Rectitude. passions, affections, as respecting such objects, and in such degrees; and of the several actions consequent thereupon. In this survey it approves of one, disapproves of another, and towards a third is affected in neither of these ways, but is quite indifferent. This principle in man, by which he approves or disapproves his heart, temper, and actions, is *conscience*.¹ "That principle by which we survey, and either approve or disapprove our own heart, temper, and actions, is not only to be considered as what is in its turn to have some influence; which may be said of every passion, of the lowest appetites: but likewise as being superior; as, from its very nature, manifestly claiming superiority over all others, insomuch that you cannot form a notion of this faculty, conscience, without taking in judgment, direction, superintendency. This is a constituent part of the idea, that is of the faculty itself; and to preside and to govern, from the very economy and constitution of man belongs to it. Had it strength as it had right, had it power as it had manifest authority, it would absolutely govern the world."² Such, in Butler's own words, is the substance of his theory of conscience; and this, so far as his words go, is unimpeachably correct. But if it be viewed as intended to furnish a theory of rectitude, it must be pronounced deficient; for, as Mackintosh observes, if to the question, What is the distinguishing quality common to all right actions? "it were answered, 'Their criterion is, that they are approved and commended by conscience,' the answerer would find that he was involved in a vicious circle; for conscience itself could be no otherwise defined than as the faculty which approves and commends right actions."³ It may be questioned, however, whether Butler be justly amenable to the charge of having offered so defective a theory. Though, with that preference for the actual to the speculative, which is characteristic of him, he chooses rather to vindicate moral truth by showing how it accords with, and is enforced by, the constitution of man, than to investigate its abstract foundation, he by no means overlooks the latter inquiry, still less does he offer his own conclusions as tending to supersede it. On the contrary, he distinctly states that the method "which begins from inquiring into the abstract relations of things" affords "the most direct formal proof," and that it and the method be has followed "exceedingly strengthen and enforce each other."⁴ From casual statements in different parts of his writings it would appear that Butler held the foundation of morals to lie in the nature of things, as understood by him (of which more hereafter), and so really belonged to the class of intellectualists on this question.⁵

B. 3. The theory which bases rectitude on sympathy stands associated with the name of Dr Adam Smith. In his charming and instructive book entitled *The Theory of Moral Sentiments; or, an Essay towards an Analysis of the Principles by which men naturally judge concerning the conduct and character first of their neighbours and afterwards of themselves*, he has developed this theory with all his wonted clearness, grace, and genius. The following sentences will suffice to place it in substance before the reader:—"To approve of another man's opinions is to adopt those opinions, and to adopt them is to approve of them. . . . But this is equally the case with regard to our approbation or disapprobation of the sentiments or passions of others." "In the suitableness or unsuit-

ableness, in the proportion or disproportion, which the affection seems to bear to the cause or object which excites it, consists the propriety or impropriety, the decency or ungracefulness, of the consequent action." "When we judge of any affection as proportioned or disproportioned to the cause which excites it, it is scarce possible that we should make use of any other rule or canon but the correspondent affection in ourselves. If, upon bringing the case home to our own heart, we find that the sentiments which it gives occasion to, coincide and tally with our own, we necessarily approve of them as proportioned and suitable to their objects; if otherwise, we necessarily disapprove of them as extravagant and out of proportion." "Originally we approve of another man's judgment, not as something useful, but as right, as accurate, as agreeable to truth and reality; and it is evident we attribute these qualities to it for no other reason but because we find that it agrees with our own."⁶ "When I endeavour to examine my own conduct—when I endeavour to pass sentence upon it, and either approve or condemn it, it is evident that, in all such cases, I divide myself, as it were, into two persons, and that I, the examiner and judge, represent a different character from that other I, the person whose conduct is examined into and judged of. The first is the spectator, whose sentiments with regard to my own conduct I endeavour to enter into by placing myself in his situation, and by considering how it would appear to me when seen from that particular point of view. The second is the agent—the person whom I properly call myself, and of whose conduct, under the character of a spectator, I was endeavouring to form some opinion."⁷ From these statements it appears that the following constitute the integral elements of Dr Smith's system:—1. That to approve of any man's sentiments or conduct is tantamount to believing that, under similar circumstances, we ourselves would have felt or acted as he has done. 2. That the propriety of affections depends upon their suitableness, as measured by the proportion borne by them to their exciting cause. 3. That of this proportionateness the only rule or measure is our own sympathy with these affections; that is, our conviction that in similar circumstances we should have entertained them and no others. 4. That we pronounce the judgment of another right for no other reason but because it agrees with our own. 5. That in judging of our own affections and conduct we use, as a measure, the sentiment which they would excite in us if viewed from the stand-point of another; and pronounce them right or wrong accordingly.

In judging of this system with reference to the point at present before us, it is necessary to keep in mind that the question is not as to the existence and functions of sympathy as a psychological phenomenon; nor is it as to the advantage, in a practical point of view, of endeavouring to place ourselves in the position of others before we pronounce any judgment on their feelings or conduct; nor is it as to the influence which the presumed judgments of others have upon our own judgments and behaviour; nor is it as to the process by which the moral faculty is historically brought into active operation in the soul of man. The question is, Does the quality which constitutes an action *right* arise out of that sympathy on the part of the spectators to which Dr Smith appeals?

¹ *Sermons on Human Nature*, p. 11, Oxf. 1826.

² Same book, p. 36.

³ *Diss.*, p. 363.

⁴ Preface to *Sermons*, p. vii.

⁵ Compare such statements as the following:—"The moral faculty may be understood to have these two epithets, *δοκιμαστική* and *ἀποδοκιμαστική*, upon a double account; because, upon a survey of actions, whether before or after they are done, it determines them to be good or evil; and also because it determines itself to be the guide of action, of life, &c." (*Diss. on Virtue*, p. 319, note a.) "Conscience, . . . whether considered as a sentiment of the understanding, or as a perception of the heart, or, which seems the truth, as including both." (p. 320.) "Moral precepts are precepts, the reasons of which we see; moral duties arise out of the nature of the case prior to external command." (*Anal.*, part ii., c. i.) "Vice is contrary to the nature and reason of things." (Pref. to *Sermons*, p. vii.)

⁶ Part i., § i. c. 3 and 4.

⁷ Part III., c. 2.

Rectitude. To this question it must be confessed that only a negative answer can be returned. Allowing to sympathy all the influence and force which Dr Smith ascribes to it, it must nevertheless be pronounced wholly inadequate to sustain the superstructure which he has sought to erect upon it. His theory stands exposed to the following among other objections:—1. It assumes a fact as given in consciousness which consciousness refuses to own. The process of transferring ourselves into the position of another, in order to judge of the rectitude of his affections by supposing them our own, or of placing ourselves in the position of a spectator, in order to judge of the rectitude of the affections we ourselves indulge, is one which could not go on without our being conscious of it. But in the multitudinous instances in which we pronounce moral judgment on others or on ourselves, how seldom is it that we are conscious of any approximation to such a process of reflection! The man who sees an unjust blow given, or who recoils from the suggestion of a tempter, passes instantaneously from the perception of the object to the moral judgment upon it; and no process of after reflection awakens in him the slightest consciousness that his *reason* for this judgment was furnished by such a transference of parties as Dr Smith supposes. Such utter unconsciousness of a process, upon which the entire validity of the judgment is assumed to rest, seems irreconcilable with the hypothesis of its existence. 2. Supposing the alleged process to take place, it affords no ground for the judgment pronounced. The conviction in the mind of A, that, if placed in the circumstances of B, he would have acted as B has acted, simply proves a similarity in his moral constitution with that of B; it proves nothing as to the rightness or the wrongness of the action itself. In order to reach this we must suppose A to approve the conduct of B as what in his own case he would have held to be *right*. But this presupposes a *previous* knowledge of the distinction between right and wrong; and, consequently, a foundation for this distinction different from, and prior to, our sympathy with the agent. In point of fact Dr Smith tacitly assumes this; and thereby lands himself in the same vicious circle as we have seen to be fatal to the theories already examined. "I cannot but regard the very celebrated theory of Dr Smith," says Dr T. Brown, "as involving, in morals, the same error that would be involved in a theory of the source of light, if an optician, after showing us many ingenious contrivances by which an image of some beautiful form may be made to pass from one visible place to another, were to contend that all the magnificent radiations of that more than ethereal splendour which does not merely adorn the day, but constitutes the day, had their primary origin in *reflection*, when reflection itself implies, and cannot be understood but as implying, the previous incidence, and therefore the previous existence, of the light which is reflected."¹ 3. Dr Smith's theory, in its primitive form, offers no account of the *imperativeness* which we invariably associate with the conception of right. That we approve the act of another as what we, if in his place, would have done, leaves altogether unaccounted for the conviction with which that approval is accompanied, that the act is such as *ought* to have been done. Dr Smith is far from overlooking this conviction; he repeatedly and emphatically asserts the imperativeness of moral rectitude. But in order to reconcile this with his theory of sympathy, he resorts to an expedient which virtually sets aside that theory. He says there is "a tribunal established in our own breasts which is the supreme arbiter of all our actions;" and this he ingeniously describes as the conception "of a person quite candid and equitable, of one who has no par-

Rectitude. ticular relation either to ourselves or to those whose interests are affected by our conduct, who is neither father nor brother nor friend to them or to us, but is merely a man in general, an impartial spectator, who considers our conduct with the same indifference with which we regard that of other people." From this it appears that it is not our sympathy with any of our fellow-men who may be supposed to witness our conduct, but our sympathy with this imaginary man, this "abstract man, the representative of mankind and substitute of the Deity," that determines the rectitude of our sentiments and actions. But what is this "man within" but some recognised standard of right and wrong existing independent of us, and recognised by us as the supreme arbiter of our actions—in reality something without us, but appearing to be within us, because realized as a conception of our mind? By this theory, then, of Dr Smith, as completed by himself, we are ultimately taken off the ground of emotionalism and conveyed to that of intellectualism for a basis of moral distinctions; so that its only advantage is, that it conducts us by a flowery and pleasant path, through a needless detour, to a conclusion more solid and sound than it promised. It is not without reason that the elaborate device of the author to save his peculiar theory, without renouncing the certainty or permanency of moral distinctions, has been compared to the expedients of the Ptolemaic astronomers who, "to save appearances," proposed to

"Gird the sphere
With centric and eccentric scribbled o'er
Cycle and epicycle, orb in orb."²

B. 4. This theory will be found most ably developed in the Lectures of Dr Thomas Brown. According to him the basis of moral distinctions lies in the emotional constitution of the human mind,—in the feeling of approbation which a virtuous action awakens in us towards the agent. He denies that right and wrong are qualities of actions, and contends that they simply express a relation to the emotional part of our nature; that which we pronounce right being that which excites in us approbation, that which we pronounce wrong being that which excites in us censure or blame. "Right and wrong," says he, "signify nothing in the objects themselves. They are words expressive only of relation, and relations are not existing parts of objects, or taken from them. There is no right nor wrong, virtue nor vice, merit nor demerit, existing independently of the agents who are virtuous or vicious; and, in like manner, if there had been no moral emotions to arise on the contemplation of certain actions, there would have been no virtue or vice, merit or demerit, which express only relations to these emotions."³ "If," says he in another lecture, "a particular action be meditated by us, and we feel, on considering it, that it is one of those which, if performed by us, will be followed in our own mind by the powerful feeling of self-reproach, and in the minds of others by similar disapprobation; if a different action be meditated by us, and we feel that our performance of it would be followed in our own mind and the minds of others by an opposite emotion of approbation, this view of the moral emotions that are consequences of the actions is that which I consider as forming what is termed *moral obligation*,—the moral inducement which we feel to the performance of certain actions, or to abstinence from certain other actions. . . . Our action in the one case we term morally right, in the other case morally wrong; *right* and *wrong*, like virtue and vice, being only words that express briefly the actions which are attended with the feeling of moral approbation in the one case, of moral disapprobation in the other case."⁴ On this

Rectitude. theory of moral distinctions the following strictures may be offered:—

(i.) This theory is incompatible with the doctrine of the *reality* and *permanency* of moral distinctions. Of this doctrine Dr Brown is himself a zealous and eloquent advocate; but he appears to have forgotten it when constructing his own theory of the foundation of such distinctions. For if right and wrong be terms expressive of a mere relation of certain actions to the human mind, it follows that, the constitution of the human mind being altered, the relation would be disturbed, might even be reversed, so that what is now wrong might become right, and *vice versa*. That which is based on what is arbitrary and mutable can never be itself essential and permanent.

Dr Brown does not shrink from the avowal that, as the constitution of the mind might be altered, our moral judgments might be the reverse of what they now are; but he endeavours to defend his doctrine from the charge that it makes rectitude precarious and changeable, by affirming that the relations of morality are not more exposed to this objection than the relations of mathematics. "It is not to moral distinctions only that this objection, if it had any force, would be applicable. *Equality, proportion*, it might be said, in like manner, signify nothing in the objects themselves to which they are applied more than *vice* or *virtue*. They are as truly mere relations as the relations of morality." Now, in arguing thus, Dr Brown has either argued irrelevantly, or he has argued against himself. It is granted that equality is the concept of a relation; but the question arises, A relation of what, and to what? Is it of a certain object to the mind? Certainly not; but of the object to some other object. Either, then, the relations of morality are of the same kind as the relations of equality, or they are not. If they are not, Dr Brown's illustration, drawn from the latter to the former, is irrelevant; if they are, their rectitude is not the relation of an action to the mind, but the relation of the action to something else out of the mind, viz., to some standard of rectitude existing independently of the mind and its feelings. The confusion into which Dr Brown has been betrayed in this attempt to defend his theory from a fatal objection becomes still more manifest as he proceeds. "Though the three sides of a right-angled triangle," he continues, "exist in the triangle itself, and constitute it what it is, what we term the properties of such a triangle do not exist in it, but are results of a peculiar capacity of the comparing mind. It is man, or some thinking being like man, whose comparison gives birth to the very feeling that is termed by us a discovery of the equality of the square of one of the sides to the squares of the other two; that is to say,—for the discovery of this truth is nothing more,—it is man who, contemplating such a triangle, is impressed with this relation, and who feels afterwards that it would be impossible for him to contemplate it without such an impression. If this feeling of the relation had never arisen, and never were to arise, in any mind, though the squares themselves might still exist as separate figures, their equality would be nothing, exactly as justice and injustice would be nothing, where no relation of moral emotion had ever been felt."¹ This passage is full of errors, and one can account for its being found where it is only by remembering with what haste Dr Brown's lectures were composed, and how they were sent forth to the public without the benefit of his superintending and correcting hand. Had he ever carefully reviewed this passage he would not, we believe, have allowed himself to appear before the public as affirming that it is the three sides of a right-angled triangle that *constitute* it what it is,—that the mind may *discover* what has no existence,—that a discovery is a *feeling*,—that the mind, by comparing, may find

out properties which do not exist,—and that two objects may be equal to each other, and yet their equality be "nothing" apart from a perceiving mind. But not to dwell on these incoherences, is it not evident that Dr Brown's illustration is altogether against his own theory? As the equality of the square of the hypotenuse to the sum of the squares of the sides of a right-angled triangle does not arise from their relation to the mind, as little does the rectitude of one action and the wrongness of another arise from the relation of such to the mind; and as the perception of the equality of objects is the result of the mind's comparing these objects with each other, so the perception of the rectitude of actions is the result of the mind's comparing these with some standard of right and wrong. From this it follows conclusively that the basis of this distinction cannot be in the mind itself.

(ii.) On Dr Brown's theory it is impossible to account for the existence in the mind of the judgment of right or wrong in reference to any action. By the hypothesis there is nothing in the action itself to originate such judgments; they arise simply and solely from the mind's feeling approbation or disapprobation on perceiving the action. But what originates this feeling in the mind? It cannot be self-caused; and if not self-caused, what is there to cause it but something in the action itself? Dr Brown's system thus leads to a contradiction. Had his position been, that rectitude is a quality of actions which the mind is adapted to approve, and that on the perception of that quality in any action a feeling of approbation arises within us in reference to the agent, all would have been clear and intelligible; but when we are told that rectitude is only a relation between a certain action and an emotion of the mind, which emotion must exist before the rectitude can be perceived, all is thrown into inextricable confusion. We have the mind approving where there is nothing to approve; an emotion arising which there is nothing to excite; and a conception formed, as the *result* of an emotion, which can only exist where that conception is presupposed.

(iii.) Dr Brown's theory obliterates the distinction between Ethics and Psychology, by identifying what *is* with what *ought to be*. No writer has more distinctly than he enunciated the necessity of keeping these two questions separate. "When we know," says he, "that man has certain affections and passions, there still remains the great inquiry as to the propriety or impropriety of those passions, and of the conduct to which they lead. We have to consider not only *how* he is capable of acting, but also whether, acting in the manner supposed, he would be fulfilling a duty or perpetrating a crime."² In pursuance of this distinction, Dr Brown has considered the emotions of moral approbation and disapprobation, viewed as affections of the mind, as falling within the psychological (or, as he chooses to designate it, the physiological) department of his course. Here he analyzes these emotions as they are, and this is all with which Psychology has to do. But when he comes to Ethics he has further to inquire into the moral propriety or impropriety of these emotions. This inquiry, however, he very inconsistently waives in reference to these emotions, and sets out with the assumption that these are what they ought to be simply because they are,—nay, are themselves the source and criterion of the propriety or impropriety of actions. If any other emotion arise in the mind, we may ask concerning it, Is it right or wrong? and to answer this we must appeal to our emotion of moral approbation or disapprobation: but when this emotion itself arises we may not ask such a question concerning it; the mere existence of it determines that it is as it ought to be. Now, why this departure in this one instance from a principle recognised and pleaded for in every other? Why

¹ Lect. lxxxii., vol. ii., p. 177.

² Lect. i., vol. i., p. 9.

Rectitude. is one affection of the mind to be assumed to be always right simply because it exists, while other affections of the mind must depend upon it for their moral character? Why, above all things, should that by which other affections are to be proved right or wrong, be *assumed* to be itself certainly right without any proof? "It is obvious," as has been justly observed, "that Dr Brown takes for granted the propriety of the feelings of approbation; and indeed he must do so. And taking this for granted, the system supplies us with no certain measure of the rectitude of any action, or of any affection of mind whatever. The correctness of the rule not being verified, we can have no confidence in relation to the correctness of anything that is measured by it. The whole system of morals is thus involved in doubt and uncertainty; and it is impossible, on this scheme, for any man to know whether he deserves the vengeance or the love of his fellow-men."¹

(iv.) It is impossible to understand, on Dr Brown's theory, in what sense rectitude can be ascribed to God. That God is right in all his ways is a dictate of all religions, as well of nature as of Scripture. But if rectitude be a mere relation of actions to the mind, in what sense can the actions of God be pronounced right? *Whose* mind is it, by their relation to which the rectitude of these actions is determined? Not, of course, that of any of God's creatures; for this were to make the character of God and his ways dependent on the feelings of a finite and perhaps erring being. Not his own mind; for we cannot without absurdity say that God's actions are right because, when He has done them, they are approved by Him, or were so when he foresaw that he would do them. Dr Brown's system seems here wholly at fault. Reason and piety alike constrain us to say that God's actions are right, because they are all perfectly conformed to an absolutely perfect standard of rectitude.

(v.) Experience teaches us that men may very sincerely and conscientiously approve actions which other men see to be wrong, and which they themselves afterwards as sincerely and conscientiously pronounce blameworthy. In such a case, according to Dr Brown's theory, the same action would be both right and wrong at the same time to different persons, and at different times to the same person. Does not such a conclusion go entirely to unsettle the foundations of morality? What confidence can one have in moral distinctions, if the mere fact that our contemplating a certain action with approbation makes it right for us to do it, and that when we change our feeling with regard to it, we become bound not to do it? Besides, does not the fact that we may change our moral estimate of actions in consequence of greater knowledge or greater mental purity, show of itself that the rectitude of actions depends upon something out of ourselves,—something appertaining to the action which we require justly to apprehend before we can feel approbation of it or of the doer of it?

On these grounds the theory of Dr Brown, ingeniously as he has illustrated it, appears altogether untenable.

Before leaving the emotional theories of rectitude, there are one or two observations of a general nature which may be hazarded in reference to certain particulars which affect them in common.

(i.) They all agree in founding moral distinctions on the existing constitution of the human mind. Dr Brown expressly avows this with reference to his theory;² and it is no less true with reference to the others. Whether we resolve rectitude into a dictate of conscience, a result of sympathy, or a perception of the moral sense, we alike base it upon something in man's existing mental constitution.

(ii.) Though the authors of these theories all agree in repudiating the doctrine which finds the basis of rectitude

in the will of God, the ground they have assumed in common is one which conducts ultimately to this doctrine. For as man is God's creature, his constitution, bodily and mental, is simply that which God willed him to have; and thus, as his constitution depends entirely on the Divine will, whatever depends upon his constitution must be resolved ultimately into that will. We may, indeed, ask why God willed man to possess such a moral constitution as He has given him; and we may find an answer to this in the position, that God ever does that which is right and best; but from such an inquiry and such an answer those who place the foundation of rectitude and goodness in certain emotions of the human soul, preclude themselves by the ground they have assumed.

(iii.) All these theories proceed upon the assumption, that the moral constitution of man remains in its normal state. This is essential to the validity of their appeal; for if man's moral constitution be in a state of disorder or disease, we can no more trust to its decisions in matters of right and wrong, as an independent and original source of moral distinctions, than we could to the reflections of an ill-polished mirror or to the sensations of a jaundiced eye. In making this assumption, however, they have overlooked a fact to which all experience, no less than Divine revelation, gives testimony, that man's moral constitution, so far from being in the state in which it ought to be, is in a condition wholly abnormal and disordered. It is true that this state does not amount to a destruction of man's moral constitution; he is still susceptible of moral impressions, still capable of moral judgments; and enough remains to enable us to determine what the order of his moral nature originally was. But with all this there is so much of perversion, confusion, and disorder, that we can have no security that what his moral tastes or affections may approve shall be on that account right and proper.

II.—*Intellectual or Objective Theories.*

We proceed to the consideration of these with a presumption that, in this department of speculation, we shall find the object of which we are in search. This presumption is founded not only on the fact that we have failed to find it in the emotional part of our nature, but also because of the intellectual character of our moral cognitions. When we say, "This is right," we do not give expression to an emotion; nor do we utter a wish; nor do we express a resolution: we pronounce a judgment. Now, as a judgment is an intellectual act, the presumption is, that the basis on which this judgment rests will be some datum or discovery of the intellect.

C. 1. This theory, according to which rectitude depends on civil enactment, is generally cited as owing for its principal exponent and advocate "the philosopher of Malmesbury," Thomas Hobbes. To this dubious honour Hobbes has contributed to raise himself by the manner in which he has repeatedly expressed his views; but it is more than doubtful whether such a doctrine can be justly fixed upon him. Mr Stewart has remarked, that "the ethical principles of Hobbes are completely interwoven with his political system;"³ and this must ever be borne in mind in estimating his views. The great problem which he has set himself to solve is apparently this:—Given a community, composed of men such as men usually are, how may peace and order be best secured in the administration of its affairs? And of the solution which he offers part is this, that men in such a community must not be allowed to judge each one for himself what is good and what is bad, what is *meum* and what is *tuum*, what is just and what is unjust; but all this must be determined by the enactment of the ruling power. Hence his writings contain such startling assertions as the

Rectitude.

Rectitude. following:—"Quod legislator præceperit, id pro bono, quod vetuerit, id pro malo habendum esse. . . . Ante imperia *justum et injustum* non extitere; ut quorum natura ad mandatum sit relativa; actioque omnis sua natura adiaphora est; quod justa vel injusta sit a jure imperantis provenit. Reges igitur legitimi quæ imperant justa faciunt imperando, quæ vetant vetando injusta. Privati autem homines dum cognitionem boni et mali ad se trahunt cupiunt esse sicut reges; quod salva civitate non potest."¹ "Culpa, hoc est peccatum, est quod quis fecerit, omiserit, dixerit, vel voluerit contra rationem civitatis, id est contra leges."² "In a state of nature nothing can be unjust; the notions of right and wrong, justice and injustice, have there no place; where there is no common power, there is no law,—where no law, no transgressions."³ "No law can be unjust."⁴ Many similar statements might be adduced from the two works from which these sentences are taken; and such statements, it cannot be denied, if taken by themselves, would fully justify the imputation to Hobbes of the opinion, that it is by the authority of political enactment that justice and injustice, right and wrong, are produced. All, however, that he appears to have intended by them is, that in a state the governing power must settle the conditions of property; and by its enactment, and not by the opinions of each individual, must the duty and the right of each, as a member of the body politic, be determined. That he did not consider his inquiry as directed to the settling of general principles of morals, but only to the determining of the authority, by which, in a state, the boundaries of good and evil should, for governmental purposes, be fixed; and that he held moral distinctions to be in themselves independent of civil enactment, may be clearly shown from many parts of his treatise *De Cive*. Thus, in reference to theft, he says,—"Non quærimus an furtum sit peccatum; quærimus quid furtum dicendum sit, et sic de cæteris similibus."⁵ According to this, his design is not to determine the moral virtues, but only to ascertain by what authority such and such acts are to be held breaches of these virtues. This obviously implies that these virtues themselves rest on something else than, and anterior to, civil enactment for their basis. Still more explicitly and fully is this stated in the following passage:—"Doctrinarum quæ ad seditionem disponunt una et prima hæc est; cognitionem de bono et malo pertinere ad singulos. In statu quidem naturali ubi jure æquali singuli vivunt, nec se per pacta sua aliorum imperio submiserunt veram eam esse concedimus, imo cap. i., art. 9, probavimus. Sed in statu civili falsa est. Ostensum enim est, cap. vi., art. 9, Regulas boni et mali, justî et injusti, honesti et inhonesti esse leges civiles, ideoque quod legislator præceperit id pro bono, quod vetuerit et pro malo habendum esse."⁶ Here the author distinctly states, that in a state of nature every man can and may judge for himself what is right or wrong; and that it is only when he has entered into a civil compact that he becomes bound to allow the state to fix the rules of rectitude for him. Such a doctrine may be very unsound politically, but it does not amount to anything like an affirmation that moral distinctions, as such, have their origin in civil enactment. On the contrary, in that part of his work to which he here refers (the first chapter), Hobbes shows at length that there are natural laws prescribing to man what he ought to do; that these

laws are immutable and eternal; that they bind man *in foro conscientiæ*; that they are nothing else than certain conclusions understood by reason concerning things to be done and things to be omitted; that they are identical with the moral law; and that they may justly be called *divine*, "not only because reason, which is itself the law of nature, has been given immediately by God to each man as the rule of his actions, but also because the precepts of living thence derived are the same as those which have been promulgated by the Divine Majesty as laws of the heavenly kingdom, through our Lord Jesus Christ and the holy prophets and apostles."⁷ These sentiments appear altogether incompatible with the theory of moral distinctions usually imputed to Hobbes. It belongs to another department to examine the soundness of Hobbes's doctrine concerning the relation of subjects to their governors.

The opinion which has been thus injuriously imputed to Hobbes was certainly, however, held by some ancient philosophers, as Cudworth has showed in his learned way by numerous citations.⁸ Unfortunately, these are for the most part given in such a way, that we have been unable to verify them all; and of those we have succeeded in tracing, all do not appear apposite to the purpose for which they are cited. When every deduction, however, has been made on these accounts, there still remains enough to prove that there were philosophers in ancient times who not only affirmed what Hobbes has affirmed as to justice and injustice, good and evil, being determined by law, but who affirmed also what Hobbes has denied, viz., that such distinctions are not also by nature.⁹ Now to all such doctrines the answer is sufficiently obvious. A law, as law, is the mere expression of the supreme will in a community, and can never confer a moral character on any act to which it relates. The utmost law can do is to indicate that a given course will be followed by a given punishment, and so to affix a character of imprudence or folly to the pursuing of that course. It can never *per se* make that which was before right to become wrong, nor that which was before wrong to become right. "A sovereign," as has been truly said, "may enact and rescind laws, but he cannot create or rescind a single virtue;" nor can any mere expression of his will, or any penalty he may attach to the violation of it, awaken one feeling of remorse or self-condemnation in the bosom of the man who transgresses the law under a clear and firm conviction that it enjoins what a regard to a higher law—the law of rectitude or of God—forbids. The mere utterance of will can never of itself add moral qualities to an act, or bring one under an obligation to perform it; and it matters not whether this will be that of an individual or of a community, for mere numbers in a case of this sort go for nothing: where $x=0$, $100x$ or $10,000,000x$ amount to no more. As Dr Brown puts it (though he erroneously ascribes this argument to Cudworth), "it must either be right to obey the law, and wrong to disobey it, or indifferent whether we obey it or not. If it be morally indifferent whether we obey it or not, the law which may or may not be obeyed with equal virtue cannot be a source of virtue; and if it be right to obey it, the very supposition that it is right to obey it implies a notion of right and wrong that is antecedent to the law, and gives it its moral efficacy."¹⁰ It is not easy to conceive what could be said in reply to this.

¹⁰ *Lectures*, vol. iii., p. 632. It is worthy of notice that Stewart as well as Brown imputes this dilemmatical reasoning to Cudworth. See *Active and Moral Powers*, vol. i., p. 240. Both were led into the mistake by Dr Adam Smith; see his *Theory of Moral Sentiments*, part vi., § 3, c. 2.

Rectitude. In the minds of many, however, there is a confused impression, that because it is morally right for subjects to obey their rulers; therefore whatever the ruler may prescribe becomes *ipso facto* right, and consequently, that it is into the will of the ruler that rectitude is ultimately to be resolved. Now a very little reflection will suffice to show, that even assuming this reasoning to be well founded, it will apply to only a very small part of what concerns man as a moral agent; by far the greater part of his moral obligations relating to a sphere within which no legislation of his fellow-men can penetrate. It will occur also to the inquirer to ask,—If the will of the ruler determine the moral obligations of his subjects, what is it that determines the moral obligations of the ruler? He is not free from these; for this would be to deny to him the attributes of an intelligent creature; and if these have come upon him from some source superior to his own will, and anterior to the exercise of it, then moral distinctions cannot be *created* by him, and consequently conduct cannot become right simply because he commands it. Further, the question will arise,—On what rests the obligation incumbent on subjects to obey their rulers? Not surely on law; for mere law can never create an obligation: it can only prescribe how a previously existing obligation is to be followed. But if not on law, then on something anterior to law and above it; so that we are again brought to the conclusion, from the very relation of governor and subject, that there is a foundation for rectitude wholly independent of any legislation or utterance of rectoral will. “It was never heard of,” says Cudworth, “that one founded all his authority of commanding others, and others’ obligation or duty to obey his commands, in a law of his own making, that men should be required, obliged, or bound to obey him. Wherefore, since the thing willed in all laws is not that men should be bound or obliged to obey, this thing cannot be the product of the mere will of the commander; but it must proceed from something else, namely, the right or authority of the commander, which is founded in natural justice and equity, and an antecedent obligation to obedience in the subject which things are not made by laws, but presupposed before all laws to make them valid. And if it should be imagined that any one should make a positive law to require that others should be obliged or bound to obey him, every one would think such a law ridiculous and absurd; for if they were obliged before, then this law would be vain and to no purpose; and if they were not before obliged, then they could not be obliged by any positive law, because they were not previously bound to obey such a person’s commands; so that obligation to obey all positive laws is older than all laws, and previous or antecedent to them.”¹ In fine, it will occur to the thoughtful inquirer, that as the obligations lying on subjects to obey their rulers is thus imposed by an authority above and anterior to that of any ruler, so the limits of this obedience must be determined by a regard to this higher authority. His authority can never ascend beyond its own source; and if, consequently, he shall command what the source of his own authority forbids, the obligation resting on his subjects to obey him necessarily terminates *quoad hoc*. This leads to the conclusion, on the one hand, that a ruler is to be obeyed only so far as he enjoins what is morally right; and, on the other, that so far from his law creating the rectitude of actions, it is by the standard of rectitude that the moral validity of his own law is to be tried.

C. 2. Closely connected in principle with the doctrine just examined, though proceeding from very different parties, and urged with very different views, is the opinion that

Rectitude. rectitude is to be resolved into the sovereign will of God. Cudworth traces this opinion to Ockham, from whom he quotes the statement, “That there is no act evil but as it is prohibited by God, and which cannot be made good if it be commanded by God; and conversely.”² But it is certain that, in holding this opinion, Ockham only followed his master, Duns Scotus, as did many others of the Scotists.³ The opinion has found many advocates in more recent times, some of whom have not shrunk from following it to the extreme consequence, that God may enjoin on us what we now regard as the greatest crimes, but which would then become as great virtues. Descartes, as Cudworth shows, throws himself so energetically into the defence of this opinion, that he does not hesitate to affirm “that God did not will the three angles of a triangle to be equal to two right angles because he knew it could not be otherwise, but because he willed the three angles of a triangle to be necessarily equal to two right angles,—therefore this is true, and cannot be otherwise;” thus resolving all truth, necessary as well as contingent, into the mere sovereign will of God. A leaning to this view may also be found in Bishop Taylor, and in several of the casuistical and mystical theologians. In judging of opinions on this subject, however, we have ever carefully to keep in view the distinction between the will of God as a rule and directory of conscience, and the will of God as a source of moral distinctions. The former opinion may be held where the latter is repudiated, as it is, for instance, by Suarez, who says, “*Hæc Dei voluntas, prohibitio aut præceptio, non est tota ratio bonitatis et malitiæ quæ est in observatione vel transgressionem legis naturalis, sed supponit in ipsis actibus necessariam quandam honestatem vel turpitudinem, et illis adjungit specialem legis divinæ obligationem.*”⁴

There can be no doubt that many who have given in to the opinion now under consideration, have done so from a pious desire to uphold the majesty and authority of God as the moral governor of the universe. Such motives are to be respected; but this must not prevent our pronouncing the opinion to which they have given currency not only unsound in principle, but most pernicious in tendency. It is at once, indeed, admitted that God can never enjoin anything but what is right and good; that whatever He enjoins, it is the duty of his creatures on whom it is enjoined to obey; that His law is the safest and surest rule by which any man can direct his conduct; and that, in actual practice, no man needs any other or higher reason for doing what God enjoins than is furnished by the simple fact that He has enjoined it. But, after all this has been conceded, the question arises: Does the mere utterance of the Divine will, pronouncing any course of conduct to be right, *create* and *constitute* the absolute rectitude of that conduct? In other words—would that which we now feel and believe to be right cease to be so, could it be shown that God has never commanded it? Or, in other words still,—would the Divine command (supposing it possible for such a thing to occur) be sufficient of itself to alter all our present moral convictions and relations, so as to make that which it is now right for us to do, wrong, and conversely? These questions the theory now under consideration would answer in the affirmative; and such answer we hold to be unsound and mischievous. In proof of this, the following observations may be adduced:—

(1.) This theory asserts that the distinction between vice and virtue is purely arbitrary; and that, consequently, there is no intrinsic excellence in virtue, no intrinsic turpitude in vice. All this is purely matter of appointment, and the

¹ *Treatise*, &c., p. 19.

Rectitude. emotions of approbation with which we regard the former, and of disapprobation with which we regard the latter, stand connected with a constitution which might have been so framed as to admire vice and abhor and condemn virtue. Had God so willed it, then, we might have been found contemplating such a character as that of Jesus Christ with aversion, and such a character as that of Judas Iscariot with admiration and rapture, as the noblest development of human excellence,—a conclusion against which our entire moral nature revolts, and which is as impious as it is immoral. It may, indeed, be said that it is impossible for God to will what is evil, and that consequently it is incompetent for us to reason on the supposition that he could. But if good and evil have no existence anterior to, or independent of, the expressed will of God, where is the impossibility of His reversing the distinctions between these which now exist? By the hypothesis, there is nothing right and nothing wrong apart from God's will; it is His command which imparts a moral character to what, apart from this, is neither good nor bad; what, then, is to render it impossible that He should will the one and not the other? If it be replied, that He must always will what is good, this gives up the theory, because in that case it is admitted that it is not because God wills it that any course is right, but because it is right that God wills it.

(ii.) This theory, whilst proffering homage to God, really dishonours Him. For it assumes that, in settling the most momentous relations of His intelligent creatures, He proceeded without reason, and left these to be determined by mere accident or caprice. If this be denied by the advocates of this theory, the question they will have to meet is, For what reason did God will His creatures to be virtuous? To this the only reply that can be given is, that He willed this because He saw it to be good and right. But this reply supposes that virtue, as seen by the eye of God, is good anterior to His willing it for His intelligent creatures; and consequently virtually renounces the theory now under consideration. If the theory be retained, the answer is precluded, and the alleged objection stands firm. It may be added, that this theory is dishonouring to God, further, by denying that there is any inherent excellence in the Divine character independent of God's will. For if the character of God be affirmed to be excellent in itself, it will follow that there is a foundation for rectitude and moral excellence independent of any act of the Divine will; and if, on the other hand, it be affirmed that the character of God is excellent simply because it is what He willed to have it, it follows that in that character there is no inherent, essential excellence, and that if God had so willed it, His character might have been marked by the very opposite qualities to those by which it is adorned. "According to this scheme, therefore," as has been justly remarked, "there is no original moral difference between the characters of an infinitely malevolent being and an infinitely benevolent one; because this difference depends on a mere arbitrary act of will, and not at all on the respective natures of the things themselves."¹

(iii.) This theory confounds the distinction between moral duties and positive duties. Every person will admit that it is right to do what God enjoins; but every person must feel that there is an essential difference between the command to abstain from murder, falsehood, or theft, and the command to circumcise every male child when he is eight days old, or the prohibition to eat flesh with the blood in it. The former are moral laws, which carry their reason in themselves, and are enjoined because they are right; the latter are positive laws, which derive their reason from the authority which enacts them, and are right because they are enjoined. But if it be the Divine command which gives

its moral character to any injunction, this distinction is baseless and fantastical. The only reason for any duty in that case is, that so it has been enjoined; and murder, falsehood, or theft, which would have been quite innocent had God not forbidden them, are not crimes to us in any other sense than a neglect to circumcise his child, or the eating of blood, would have been a crime to an Israelite. It is true that in the former case the law has existed since ever man existed, and is in force wherever man is found, while in the latter it was local and for a season; but if the rectitude of the acts in both cases be derived from the mere fact that they are enjoined by God, this difference does not seem to be of any moment.

C. 3. The general theory which derives the rectitude of actions from their consequences, divides itself into two sub-theories, according as these consequences are viewed either relatively to the agent himself alone, or relatively to other beings, or to being in general. In the former case rectitude is identified with what is advantageous or agreeable to the individual; in the latter it is identified with what is advantageous to the community or the race. In both cases it is assumed that there is no inherent, essential quality of rectitude in actions,—that happiness or advantage is the ultimate good, and that actions become right as they tend to promote this, and are wrong as they tend to hinder it. It may be of advantage to examine separately these modifications of the Utilitarian, or (to use the word suggested by Kant as more correct) Eudaimonistic theory of morals:—

(i.) The system which refers the rectitude of actions to their tendency to promote the advantage of the agent is commonly known as the Selfish System. It has found supporters both in ancient and more recent times; but it has never drawn to it any large amount of respectable support, and it may be questioned whether any one pretending to the name of philosopher would, in the present day, be found willing to appear as its formal defender. Still it exerts a sort of unacknowledged authority over the minds of very many; it is the form into which much of the popular and vague speculation at present afloat on morals among the masses would be reducible; and hence some remarks are required to show its unsoundness.

It is not to be denied, that with all right acts there is associated a certain amount of pleasure, and that the surest course to spend life happily is to spend it virtuously. The only question is, Does this gratification constitute the source of the rectitude? in other words, Is the tendency of certain actions to communicate pleasure to us the quality which confers on them the character of rectitude?

Now, in answer to this question, it is obvious to remark, that if it be the tendency of actions to convey pleasure to us which constitutes them right, the rectitude of actions will *vary* in proportion to the degree of this tendency, or the amount of pleasure which they are capable of yielding to us. Those actions, therefore, which afford us most gratification will, on that account, be most deserving of our moral approbation; and we shall be able at any time to increase the rectitude of an action by increasing its capacity of pleasing us, just as a cook may increase the excellence of a dish by augmenting its power of gratifying the palate. Nor is this all: it follows, further, from this doctrine, that what is right to one person may be wrong to another; nay, that what is now wrong to any one, because it makes him unhappy, may become right to him through some change of circumstances on his part, or by some modification of its qualities in relation to him. But are such conclusions in accordance with fact? Are they borne out by the moral sentiments of mankind? Do they find assent in the sincere convictions of any human being? On the contrary,

Rectitude.

¹ Dwight, *System of Theology*, Sermon xcix.

Rectitude. does not every one feel that, if conclusions like these were true, such words as *right* and *wrong*, *virtuous* and *vicious*, would be utterly superfluous, and calculated only to confuse and mislead.

We may apply another test to this doctrine. Were it true, it would follow that, in judging of the actions of others, we should approve those which conduce most to the advantage of the agent; for as we approve the actions of others in proportion as they are right, if rectitude depend on advantage, our approbation will necessarily be determined by our perception of such advantage as accruing to the individual. It would thus become proper for us to think well of the successful adventurer who had surrounded himself with the comforts of life by the violation of justice, and by trampling mercy under foot,—whose coffers were filled with gains collected by fraud and extortion, and who revelled in the fruits of deeds which had desolated many homes, broken many hearts, and sent many prematurely to the grave. There is, in fact, no sort of successful crime which, on this principle, we should not commend, our censure being reserved only for the unfortunate or the imprudent, who had failed to secure their own interest. On such a supposition, is it not idle to talk of moral distinctions, or to dignify man with the title of a moral agent?

Every person who reflects on the moral phenomena of his own nature must be aware that such perverted judgments are utterly impossible. Men, it is true, "will praise those that do well to themselves;"¹ for there is a certain feeling of admiration excited by all successful adventure, even when its end is purely selfish; but such praise is always limited by the condition, that in doing well to themselves men have not done ill to others; and it is excited, besides, not so much by the view of the advantage the individual has secured, as by the conviction that man owes a duty to himself in reference to the promotion of his own welfare, as well as to others. When it is evident that it is by the path of *crime* that men have passed to wealth, honour, or pleasure, there is in every human breast a sentiment of condemnation excited by their conduct, which no consideration of its successful result can mitigate. Nay, so certain and so strong is this sentiment, that even when we ourselves are made to reap the benefits of another's crime, we cannot but perceive and feel the evil of his conduct. The favourite of a despot who is enriched by his master's extortions, and whose passions are regaled by means of the license which his master's tyranny secures, has nevertheless within his bosom a sentiment condemnatory of his master's proceedings, which no sense of gratitude to his master can wholly obliterate, and which the degrading influences of a vile dependence can hardly blunt. "We can constrain our tongue to be false, our features to bend themselves to the resemblance of that passionate adoration which we wish to express, our knees to fall prostrate; but our heart we cannot constrain. There virtue must still have a voice, which is not to be drowned by hymns and acclamations; there the crimes which we laud as virtues are crimes still, and he whom we have made a god is the most contemptible of mankind, if indeed we do not feel, perhaps, that we are ourselves still more contemptible."² This description, though perhaps somewhat exaggerated, is substantially true; but if virtue lie in the tendency of any act to promote our individual benefit, why should it be so impossible for us to commend acts which directly minister to our advantage, or to approve of the character of one to whose agency we owe so much?

In reply to these strictures, it may be said that, in estimating the consequences of actions to ourselves, we must

take into account the *whole* of our being, and that in this case it will be found that, as no vicious course is ultimately beneficial, and no virtuous course ultimately injurious, true wisdom would dictate to all men to avoid a vicious and pursue a virtuous career. This is the form in which the Eudaimonistic theory was advocated by Epicurus, who maintained that "virtues are to be preferred for the sake of pleasure, not for their own sake, just as medicine for the sake of health;" but at the same time contended "that virtue alone is inseparable from pleasure," and that "no man can live pleasantly unless he live prudently, honourably, and justly;" and hence he consistently taught that prudence (*φρόνησις*) is the prime virtue.³ In this last assertion Epicurus avows what is sufficient to prove the inadequacy of the Eudaimonistic theory, even in this its improved form, to account for moral distinctions, or distinct moral judgments. After all, even on his own showing, the choice between right and wrong is a mere matter of *prudence*; there is nothing *morally* wrong in vice or right in virtue: the former is to be shunned simply because it leads to unpleasant consequences, and the latter to be followed simply because upon the whole it conduces to our happiness. On this theory it still remains inexplicable why men should censure vice and should commend virtue. If a man chooses to be vicious or selfish on the ground that that is the pleasanter course for him, we may pity him for the *mistake* he has made, but we have no right, on this theory, to blame him as having done wrong.

Besides, how on this theory are we to adjust the competing merits of a life of simple selfishness and a life of generous beneficence? Are these equally good? and, if not, why not? Let us take a case. Some person, writing in the name of Swift, says to the people of Ireland, "I have been bred in a careful way of life, and never ventured upon any project without consulting my pillow first how much I should be a gainer in the upshot."⁴ These are not Swift's own words, for at the time they were written he was hastening to the grave in a state of hopeless imbecility; but they paint a character such as may sometimes be found, and therefore are sufficient for our present purpose. Now, some twenty years before the date of this production, Swift wrote to Lord Carteret as follows, of his illustrious friend and countryman Berkeley:—"He is an absolute philosopher with regard to money, titles, and power; and for three years past hath been struck with a notion of founding a university at Bermudas by a charter from the crown. . . . He showed me a little tract which he designs to publish; and there your excellency will see his whole scheme of a life academico-philosophical—of a college founded for Indian missionaries, where he most exorbitantly proposeth a whole hundred a year for himself, forty pounds for a fellow, and ten for a student. His heart will break if his deanery be not taken from him and left to your excellency's disposal."⁵ In these characteristic sentences the sarcastic Dean of St Patrick's seeks to assist his friend in the "romantic design," as he calls it,—but which he could not help feeling to be also "very noble and generous,"—of resigning wealthy preferment, great prospects, refined society, scholarly resources and associations, to go to a distant and semi-barbarous colony as a pioneer of civilization and a preacher of religion, amid poverty and privation of every kind. Here, again, we have a character painted to us—happily this time a real character, though one not so frequently encountered in actual life as the former. What shall we say of the two characters on the Eudaimonistic theory? On that theory the motive in both cases was the same—personal advantage and pleasure.

¹ Ps. xlix. 18.

² Brown, *Lectures*, vol. iv., p. 72.

³ Diog. Laert., l. x., §§ 138, 140, &c.

⁴ *The Drapier's Letters to the Good People of Ireland*, 1745, in Swift's Works, vol. xxvii., p. 160, ed. 1779.

⁵ *Works*, vol. xvii., p. 153.

Rectitude. Were both, then, alike good? Is the pseudo-Swift, cautiously consulting his pillow before he committed himself to any project, that he might avoid all possible sources of personal loss and discomfort, to be equally commended and admired with the large-hearted and generous Berkeley, who, casting all personal considerations to the winds, is willing to endure penury, and toil, and trial, for a scheme which is to profit him nothing, even should it prove successful, but from which he hopes his fellow-men may reap benefit? Or if the latter is to be pronounced the better of the two, is his superiority to be determined by nothing else than a nicely-adjusted estimate of the superior amount of happiness which, in the upshot, the course he has selected is calculated to confer upon him?

But supposing we arrive at this conclusion, it may occur to one to ask, How did Dr Berkeley know, or how can any one know, *anterior to experience*, that the path of generous self-denial is productive of a larger amount of happiness than that of self-indulgence? Here the Eudaimonistic theory of human actions seems wholly at fault. For either the happiness which virtue confers is cognised by the mind previous to the virtuous action, or it is not. If it is not, then all acts of virtuous self-denial are performed either without any motive at all,—a position which the mind refuses to admit,—or they are performed for some other reason than the pleasure attendant on virtuous conduct. If, on the other hand, there is an attendant acquaintance with this pleasure, for the sake of which alone good deeds, it is supposed, are done, this can arise only from the generous desire being felt previous to the pleasure which the anticipated gratification of it yields. In either case, it is certain that it is not from selfish motives that the virtuous deed is done.

In fine, as Dr Brown has observed, “even if virtue were as selfish as it is most strangely said to be, it would be necessary to form two divisions of selfish actions: *one*, of those selfish actions of which self was the direct object; and *another*, of those very different selfish actions in which the selfish gratification was sought in the good of others. He who submitted to poverty, to ignominy, to death, for the sake of one who had been his friend and benefactor, would be still a very different being, and ought surely, therefore, to be classed still *differently* from him who robbed his friend of the scanty relics of a fortune which his credulous benevolence had before divided with him, and, not content with this additional plunder, calumniated, perhaps, the very kindness which had snatched him from ruin. By what perversion of language,” he justly asks, “is the same term to be given to affections so different?”¹

(ii.) The theory which refers the rectitude of actions to their tendency to promote the general good is commonly known as, by way of eminence, the Utilitarian theory. Though not unknown to the ancients, it is in more recent times that this theory has found its principal expounders and advocates. The first formally to develop it was Bishop Cumberland, in his elaborate treatise, *De Legibus Naturæ*, written in reply to Hobbes. It was subsequently embraced by Puffendorf, and has more recently been advocated by Hume, Paley, and Bentham. In substance it is the theory which lies at the basis of the ethical system of Edwards; and it has been avowed and defended by one of Edwards’s ablest followers, Dr Timothy Dwight. To these writers must be added Mandeville; for though he teaches that

Rectitude. virtue and vice are determined by enactment, and the sense of them acquired by education, yet he asserts that rulers, in fixing what shall be called virtue and what vice, have been guided solely by a regard to utility, making those actions virtuous which benefit the community, and those vicious which injure it.² All these writers agree in maintaining that the *utility* of actions (that is, their fitness to promote the welfare of being in general, of society at large, or to the greatest possible extent of the greatest possible number) constitutes their rectitude, and that the feeling of benevolence, or the desire so to act as to promote this utility, is the principle of virtue in an agent.

Now, it may be conceded that, in a sense, utility is inseparable from virtue and rectitude. By the gracious arrangement of the Almighty, all right actions are really useful; and it is not to be denied that to will the good of others, and to labour for that, is in itself good and right. But after all this is conceded, it still remains to be asked, Is the utility of an action that which, *per se* and *solely*, constitutes that action right? Those who would answer this question in the affirmative urge the consideration that, in a comparative view of human actions, our preference is always given to those which are most advantageous to the race, and that, apart from the tendency of virtue to make men happy, there seems no reason why it should be preferred to vice. Now, it may be granted that, in estimating the worth of virtuous actions, men usually prefer those which are most advantageous; but in order to judge of the bearing of this fact on our present inquiry, it will be needful to view it under two conditions: *first*, that the criterion of preference shall be moral rectitude, and not expediency; and, *second*, that the criterion being moral rectitude, it shall be ascertained that it is the utility of actions on which the mind fixes as the ground of its preference. If these conditions be enforced, we believe it will be found, not that the actions are preferred because they are most useful, but that those preferred, as morally best, are also found to be most useful because of the established connection between rectitude and utility; so that this fact determines nothing conclusively in favour of the Utilitarian theory. With regard to the other argument adduced, though it is one on which Dwight lays great stress,—asserting that “were sin, in its own proper tendency, to produce invariably the same good which it is the tendency of virtue to produce, . . . no reason is apparent to me why it should not become excellent, commendable, and rewardable, the same as virtue now is,”³—we cannot but regard it as a mere *petitio principii*. Of course, if virtue have no quality of its own to distinguish it essentially from vice, and if the only difference between the two lie in their tendencies, it is clear enough that the foundation of the former is to be sought in its tendency to utility; but all that is here assumed happens to involve the very point in dispute, and to be just what is required to be proved.

The fundamental objection to the theory of utility lies, we think, in this, that it proposes to find the basis of moral distinctions in what is not directly a moral quality at all. Utility is a physical and not a moral excellence. The test of this is furnished by the fact, that utility is not a quality which awakens in us moral approbation. It may excite admiration, delight, gratitude; but of itself it never awakens moral approbation. When a benefactor confers on us a favour, it is not the value of the favour that excites our

¹ *Lectures*, vol. iv., p. 69.

² Stewart has animadverted on the inconsistency of this with the doctrine with which Mandeville’s name is chiefly associated, “that private vices are public benefits.” The inconsistency is manifest, if Mandeville be regarded as meaning to inculcate that what benefits the public is, in any sense, or under any circumstances, a vice. But there is grave reason to doubt whether Mandeville ever taught, otherwise than hypothetically, the doctrine imputed to him. His reasoning is:—If national wealth be a benefit, and if certain vices promote it, then, on the basis of utility, these vices ought to be introduced as virtues. He himself solemnly declares that his entire treatise is *ironical*, and that he wrote it to refute the enemies of virtue, by subjecting their views to a *reductio ad absurdum*. See Whately’s *Lectures on Political Economy*, Lect. ii.

³ *System of Theology*, Sermon xcix.

Rectitude. moral approval; that is reserved for some quality in the benefactor, with which the utility to us of his donation has nothing to do: were it otherwise, we should regard the benevolent act which relieves a starving family with exactly the same emotion with which we regard the coins given by the benefactor for the purpose of his benevolence. But if utility be not a quality that excites in us moral approbation, then it must be fallacious to make it the basis of moral excellence; for this would be to affirm an entire discordance between moral truth and man's moral nature,—in other words, to deny the possibility of morality altogether. Then, moreover, utility is a quality which belongs to many objects which are irrational, and many which are inanimate, to none of which we ever think of ascribing moral excellence. A horse is useful, a cow is useful, a chair is useful, food is useful, and so of a multitude of other things; yet who ever thinks of ascribing to these objects the quality of rectitude or moral worth because of their utility? But if mere utility were the basis of rectitude, why should it be so? why should we refuse to ascribe moral excellence to an object which possesses in a high degree the quality which is the differential and constitutive element of moral excellence? If utility and virtue be equivalent terms, why should it seem preposterous to speak of a virtuous horse, or ridiculous to commend the moral excellence of a mahogany table? This objection, though urged by Dr Adam Smith, Dr Thomas Brown, and other eminent philosophers, is treated with great contempt by Dr Dwight. "This objection," says he, "it is hardly necessary to answer. Voluntary usefulness is the only virtue. A smatterer in philosophy knows that understanding and will are necessary to the existence of virtue. He who informs us that if virtue is founded on utility, animals, vegetables, and minerals, the sun, the moon, and the stars, must be virtuous, so far as they are useful, is either disposed to trifle with mankind for their amusement, or supposes them to be triflers."¹ This is sufficiently strong; but is it just? An action is pronounced morally good, and the question is asked, Why? To this the utilitarian answers, "Simply because its tendency is useful." "No," replies the objector, "for there are many things useful which we cannot call morally good." "Oh," says Dr Dwight, "that is a trifling objection, because when I speak of virtue I speak of what belongs only to voluntary agents." But is not this a giving up of the whole question? From this it appears that what constitutes virtue is not mere utility, but utility *plus* a voluntary and intelligent choice; and as the former element in this equation must, for the reasons above assigned, be eliminated, the latter remains as the only substantial basis of virtue. But virtue cannot be placed in mere choice; it can be found only in the *reasons* which have guided that choice. It follows, that in these reasons, whatever they may be, and not in the mere utility of the act, the element of its virtuousness must be sought.

We conclude, then, that it is not in the tendency of actions to promote either our own happiness or the welfare of others that the basis of virtue is to be sought. It is true that virtuous actions will promote both, and it is true that no higher or nobler end can be proposed by any man to himself, as an active being, than the promoting of the happiness and honour of universal being as far as he can. But still, as has been justly remarked, "it remains a question how far conduciveness even to these is what properly constitutes virtue or moral rectitude. Instead of its conduciveness to good constituting its essential nature, from its essential nature may arise its conduciveness to good. . . . The inquiry will remain, whether virtue is good *because it conduces to these ends*, or whether it does not necessarily conduce to these ends *because it is good*; in other words,

whether the system, even in the loftiest and most enlarged view of it, goes far enough back; whether there be not ultimate principles of moral rectitude necessary and eternal, existing previously to all possible trial and manifestation of their tendencies; and whether the actual evolution of the goodness of these tendencies, commencing of course with the earliest date of creation, instead of being what essentially constitutes moral rectitude itself, ought not rather to be regarded as the native and appropriate result of the principles of rectitude."²

We may conclude this discussion by citing the words of Cicero:—"Sive honestum solum bonum est, ut Stoicis placet, sive quod honestum est id ita summum bonum est, quemadmodum Peripateticis nostris videtur, ut omnia ex altera parte collocata, vix minimi momenti instar habeant: dubitandum non est quin nunquam possit utilitas cum honestate contendere. Itaque accepimus Socratem execrari solitum eos qui primum hæc, natura cohærentia, opinione distraxissent. Cui quidem ita sunt Stoici assensi ut quidquid honestum esset id utile esse censerent, nec utile quidquam quod non honestum."³

D. 1. This theory is identified with the name of Dr Samuel Clarke. It is stated by him as follows:—"That there are *different relations* of things one towards another is as certain as that there are different things in the world. That from these different relations of different things there necessarily arises an *agreement* or *disagreement* of some things to others, or a fitness or unfitness of the application of different things or different relations one to another, is likewise as certain as that there is any difference in the nature of things, or that differences do exist. Further, that there is a *fitness* or *suitableness* of certain *circumstances* to certain *persons*, and an *unsuitableness* of others founded in the nature of things, and in the qualifications of persons antecedent to *will*, and to all *arbitrary* or *positive appointment* whatsoever, must unavoidably be acknowledged by every one who will not affirm that it is equally fit and suitable, in the nature and reason of things, that an innocent being should be extremely and eternally miserable, as that it should be free from such misery. There is therefore such a thing as *fitness* and unfitness, eternally, necessarily, and unchangeably, in the nature and reason of things. Now, what these relations absolutely and necessarily are in themselves, that also they *appear to be* to the understanding of all intelligent beings, except those who understand things to be what they are not,—that is, whose understandings are either very imperfect or very much depraved. And by this understanding or knowledge of the natural and necessary relations of things, the *actions* likewise of all intelligent beings are constantly directed (*which, by the way, is the true ground and foundation of all morality*), unless their will be corrupted by particular interest or affection, or swayed by some unreasonable and prevailing lust."⁴ Again, he says, "The true ground and foundation of all eternal moral obligations is this, that the same reasons (*viz.*, the forementioned necessary and eternal different relations which different things bear to each other, and the consequent fitness or unfitness of the application of different things or different relations one to another, unavoidably arising from that difference of the things themselves),—these very same reasons, I say, which always and necessarily *do* determine the will of God, *ought* also constantly to determine the will of all subordinate intelligent beings."⁵ According to these statements, it appears that Dr Clarke placed the basis of rectitude ultimately in "the reason and nature of things," out of which have arisen certain essential differences in objects and their relations, which again have given birth to certain fitnesses or unfit-

⁵ Same book, p. 115.

Rectitude. nesses in the application of one thing to another, an intelligent conformity to which constitutes morality.

In judging of this theory it is important to bear in mind in what sense the author speaks of "the fitnesses of things." The word "fitness" is ambiguous; it may express the adaptation of one thing to another, or it may express the accordance of things with some standard by which they are judged. If we say "this is fitted to produce such or such an effect," we convey a very different conception by the word "fitted" from what is conveyed by the word "fit," when we say "it is fit that such or such an effect should be produced." Now, it is in the latter of these senses that Dr Clarke uses the term "fitness" when he speaks of the "fitnesses of things;" he intends by this phrase, not the adaptation of things in general to each other, but the accordance of things with the standard produced by their essential differences of nature and relation; in other words, congruity, or accordance with their relations. Had Dr Brown and Sir James Mackintosh sufficiently adverted to this, they would have spared some of the severest strictures they have offered on this theory.¹

It is further to be borne in mind, in justice to Dr Clarke, that in making morality consist in conformity to relations, he had not in view *all* relations, but only such as belong to the sphere of moral agency. It might be presumed that this was his reference from the nature of the subject he is discussing in the part of his book where this theory is developed—the Moral Perfection of God; and the well-known acuteness of the author might have preserved him from being supposed to maintain a theory which would have placed the constructing of a machine on strictly mathematical principles on a par, in point of moral rectitude, with the performance of an act of eminent piety or benevolence; nay, which would make the murdering of a man by a scientific regard to the relations of poison to the human system, as virtuous an act as the saving of a starving man's life by a due regard to the relations of food to the body. Dr Samuel Clarke was not quite the man to fall into a gross mistake of this sort; and had due attention been paid to his own words in the passage we have quoted, such a mistake would not have been imputed to him.² The fitnesses of which he speaks, as lying at the basis of morality, are the congruities of the actions of moral agents with the relations in which they have been placed by God—relations which he holds to be not accidental or arbitrary, but flowing out of the nature and reason of things. Here again his critics have done him grievous wrong.

When fairly viewed, the doctrine of Clarke is rather to be pronounced defective than condemned as erroneous. That it is true so far as it goes it seems impossible to deny. There can be no doubt that in the sphere of moral agency there are essential differences, out of which arise fixed and unalterable relations, and that there is a fitness or propriety of actions, and the contrary, thence resulting. The only questions which we think can be fairly mooted

in reference to the validity of Clarke's theory are, *first*, whether it does not leave us with too vague and indefinite an answer to the inquiry, "On what is rectitude founded?" and *second*, whether the author has not stopped short of a thorough exploration of the subject? It must be admitted that the phrases "fitnesses of things," "eternal and immutable relations," and even the phrase "nature and reason of things," are somewhat deficient in precision and clearness; but even were these phrases more distinctly intelligible than they are, it would still remain to inquire, Why is it that moral distinctions arise out of the nature and reason of things? We may say, morality is conformity to the fitnesses of things, and the fitnesses of things arise out of the fixed and unalterable relations of things; and these relations result from the essential differences of things; but still the question comes up, To what are these essential differences due? By "things" we are of course to understand here all beings with which moral agents have to do. Now of these "things," all, excepting God himself, are the creatures of His will, and have received their nature from Him. Shall we say, then, that in giving them each its peculiar nature He acted arbitrarily? No, replies Clarke; God was under no necessity to create; but having resolved to create, He must make things "so that they shall be disposed according to the exactest and most unchangeable laws of eternal justice, goodness, and truth." But is not this virtually to admit that the laws of justice, goodness, and truth—in short, moral laws generally—exist *antecedently* to the constitution of things, and regulate and determine that? and if so, must not a basis of moral truth be sought deeper down than in these relations or the fitnesses to which they give rise?

D. 2. This theory is advanced by Wollaston in his *Religion of Nature*. "Those propositions," says he, "are true which express things as they are; or truth is the conformity of those words or signs by which things are expressed to the things themselves." "A true proposition may be denied, or things may be denied to be what they are, by deeds as well as by express words, or another proposition. Every act of such a being as is before described (a being capable of distinguishing, choosing, and acting for himself), and all those omissions which interfere with truth (*i.e.*, deny any proposition to be true which is true, or suppose anything not to be what it is in any regard), are morally evil in some degree or other; the forbearing of such acts, and the acting in opposition to such omissions, are morally good; and when anything may be either done or not done, equally without the violation of truth, that thing is indifferent."³ This theory is substantially identical with that of Clarke; indeed, it is offered by the author as an improvement on that of Clarke, inasmuch as it affords a more precise and intelligible statement of the truth. What Clarke calls the fixed relations of things Wollaston calls the truth of things; and when Wollaston pronounces immorality to consist in acting so as to suppose anything not to be what it really is, he only reiterates Clarke's statement, that blame-

¹ See the acute and able reply of Dr Wardlaw to these strictures in his *Christian Ethics*, note E, 3d ed.

² To this may be added the following:—"That there is a fitness or suitableness of certain circumstances to certain persons, and an unsuitableness of others, founded on the nature of things, and the qualifications [qualities] of persons antecedent to all positive appointment whatever; also, that from the different relations of different persons one to another, there necessarily arises a fitness or unfitness of certain manners of behaviour of some persons towards others, is as manifest as that the properties which flow from the essences of different mathematical figures have different congruities or incongruities between themselves. . . . For instance, that God is infinitely superior to man is as clear as infinity is larger than a point, or eternity longer than a moment. And 'tis as certainly fit that men should honour and worship, obey and imitate God, rather than, on the contrary, in all their actions endeavour to dishonour and disobey Him, as 'tis certainly true that they have an entire dependence on Him," &c. (Vol. ii., p. 30.) These sentences leave no doubt that it was only in respect of the relations of moral agents that Clarke meant to predicate moral fitnesses. This passage is so worded also, that it ought to have preserved him from the charge of confounding moral and mathematical relations. It is evident he does not confound them, but simply states an analogy between them in their respective provinces. This charge is the more unjust, in that Clarke himself guards against it by articulately stating, that he did not, in making such comparisons, overlook the difference, "that assent to a plain speculative truth is not in a man's power to withhold; but to act according to the plain right and reason of things, this he may, by the natural liberty of his will, forbear." (Vol. ii., p. 40.)

³ *The Religion of Nature Delineated*, 7th ed., 8vo, pp. 5, 6, 29.

Rectitude. worthiness consists in acting as if "the proportions of things in morality were what they are not."¹ There is little ground, however, for Wollaston's boast that his modification of the theory is the superior of the two. His phraseology is even more vague and loose than that of Clarke. Taking his own definition of truth, and comparing that with his emphatic declaration, that he "would have it to be minded well" that when he speaks of acts inconsistent with truth, he means "any truth, any true proposition whatsoever, whether containing matter of speculation or plain fact," we may venture to say that no simply immoral act has ever been committed, or ever can be committed, inasmuch as any act is prompted by regard to some fact or other. It is only when couched in Clarke's more cautious phraseology that the doctrine ceases to be absurd.

D. 3. That virtue consists in living according to nature, was the doctrine of the ancient Stoics,² and in maintaining this doctrine they, by implication, placed the basis of morality in nature. In what sense this term is to be understood Cicero has explained: "When," says he, "we say that the world stands together and is administered by Nature, we mean thereby not such a thing as a clod or lump of stone, or anything of that sort, with no nature of cohering (*i.e.*, no force uniting the parts into one organic whole), but such a thing as a tree or an animal, in which there is no hazard, but order is apparent, and a certain resemblance of art."³ From this it appears that to live according to nature does not mean to live according to this or that special nature, but to live according to the organized and orderly system of the universe. And with this agrees what Diogenes Laertius says in his exposition of the stoical scheme of Ethics: "To live according to virtue," says he, "is equivalent to living according to the experience of those things that come to pass by nature, as Chrysippus says in his first book concerning ends (*περὶ τελῶν*); for our natures are parts of universal nature. Wherefore the end comes to be to live consequent to nature, that is, according to man's own and that of the universe, doing nothing which the common law is wont to prohibit, that is the right reason (*ὁ ὀρθὸς λόγος*) which pervades all, the same being in Jove, the ruler of all things that are." And again, "Chrysippus understands by that nature, consequent to which we are to live, both the common nature and that peculiar to man. But Cleanthes accepts only the common nature as that which ought to be followed, not also that which is partial."⁴

Thus explained, the Stoical system is not essentially different from that of Clarke, who places the basis of rectitude in the nature of things; and the objection which applies to the one system applies with equal force to the other. Define nature as generally as we please, it still remains to inquire, Whence came this nature, and what determined its essence? *Natura* from *nascor*, *φύσις* from *φύω*, imply *birth*, *generation*, *production*; and consequently we can never rest in mere nature as an ultimate basis. And even if nature be taken in the sense of essence, we shall not much forward the research; for the essence of a creature must be just as much derived as its form. These speculations, therefore, though true so far as they go, are chiefly useful in pointing out to us the direction in which we must travel if we would find the solution they fail to supply.

D. 4. Butler, who adopts the Stoical phraseology, and who in one place distinctly states that "moral duties arise out of the nature of the case,"⁵ and in another says that

Rectitude. "vice is contrary to the nature and reason of things,"⁶ protects himself against the objection above adduced against the system of Clarke and that of the Stoics, by the explanation he has given of the sense in which he understands "nature" in such phraseology. "The general course of nature," says he, "that is, not surely the words or ideas *course of nature*, but Him who appointed it, and put things into it; or a course of operation, from its uniformity or constancy, called natural, and which necessarily implies an operating agent."⁷ This latter statement may be elucidated by a previous statement in the same treatise. "The only distinct meaning of that word [natural] is *stated, fixed, or settled*; since what is natural as much presupposes an intelligent agent to render it so, *i.e.*, to effect it continually or at stated times, as what is supernatural or miraculous does to effect it for once."⁸ According to Butler, then, conformity to nature is conformity to God, from whom nature derived its constitution and order.

We are thus conducted to the theory which places the basis of rectitude in the nature of God. This theory must not be confounded with that which founds rectitude on the *will* of God. The will of God is His purpose, appointment, or edict; and although this must ever be in full accordance with His nature, it is no more to be identified with it than the purposes or commands of a man are to be identified with his nature. "We ought," says Price, "to distinguish between the *will* of God and His *nature*. It by no means follows, because certain things are independent of His will, that they are properly distinct from Him and independent of His nature." And he goes on to say, that to conceive that moral distinctions, being necessarily immutable and eternal, are independent of the Divine nature, "would involve us in the greatest absurdities and inconsistencies." "Wherever," he adds, "or in whatever objects *necessity* or *infinity* occur to our thoughts, the Divine eternal nature and perfections are to be acknowledged, to which nothing of this kind can be unallied."⁹

This theory contemplates the moral universe as constructed upon a plan; as not a happy accident, or a congeries of powers working now in convenience and now in contrariety, but as a *cosmos*, or well-ordered and beautifully composed system, in which each part and power is adjusted to the rest, and the whole is fitted to a great and worthy end. Now, such a plan involves principles, and these must have a basis. But where shall we search for the basis of principles that themselves lie at the foundations of the whole world? Where but in the eternal nature of Him by whom that whole has been conceived and constituted? It is so in the physical world. The outer universe is what it is because God is what He is. On the awful and eternal "I AM THAT I AM" the whole scheme and order of existence repose. The universe is the work of His hands; the plan of the universe is the utterance of His will; and the archeal principles which regulate that plan are resolvable only into the necessary perfections of His being. Now, as it is in the material, so is it in the moral world. There, too, all things are arranged in order and on plan. The relations sustained by intelligent beings to the sentient and intelligent universe, and the duties flowing out of these, are all fixed parts of the scheme under which such find themselves existing. To fulfil these relations, and to perform these duties, is the order of the moral world, and accordant with the plan on which it has been framed. But this plan

Rectitude. rests upon certain great moral principles or laws, and these again find their basis in the Divine nature. It is because God is such as He is that moral law is what it is, and that the moral world is constituted as it is. In the Divine essence, then, unchangeable and eternal, lies the foundation of rectitude—a foundation which, as it is perpetual and immutable, gives to moral distinctions that character of fixedness and perpetuity which all sound moralists have asserted as belonging to them.

This doctrine coalesces in the main with Plato's sublime speculations regarding ideas—the eternal, uncreated exemplars in the Divine mind, according to which all creature existence has been formed and all creature excellence determined. In one passage, indeed, he expressly calls God the idea or exemplar of the good:—"This, then, which furnishes truth by means of those things which are understood, and communicates to those who understand the power of doing so, say thou to be the idea of the good, and the cause of knowledge and truth as understood by the mind."¹ Cicero also, in one of the passages in which he refers to the unwritten law which is above all law, says, "Orta autem simul est cum mente divina, quamobrem lex vera atque princeps, apta ad jubendum et vetandum ratio est recta summi Jovis;" and still more tersely he says, a few lines further on, "Illa divina mens, summa lex est."² When writing these words he had probably before his mind the memorable dogma of Chrysippus the Stoic:—"No other beginning, no other genesis of righteousness, is to be found than that from Zeus and the common nature; for thence must everything of this sort have its beginning, if we propose to say aught about things good and bad."³

SECT. IV.—CRITERION OF RECTITUDE.

Having arrived at a conclusion as to the basis of moral truth, we have now to investigate the *standard* or *criterion* of rectitude; for, in the nature of the case, the basis lies hid from human view, and can no more become a guide to practice than the foundation of a house can become a fitting place of abode.

Now at first sight it may appear as if a simple and sufficient answer to this demand were furnished by that acknowledged quality of all right actions—their utility. If, it may be said, it be granted that all right actions are useful, it follows that we have only to inquire what courses are most for the well-being of ourselves and others, or of society, or of being at large, to be furnished with a safe and simple rule of moral conduct. But, though it may be conceded that in many cases this rule will suffice, and that in the ordinary business of life it is sometimes the only one we are able to apply, we must nevertheless demur to accepting it as adequate to the full exigencies of the case. For though it be true that all virtuous actions are useful, it unhappily does not follow that all actions which *appear* to us useful are virtuous; and as it is only by the appearance that man can judge in such matters, it is possible that a specious utility may often betray him into grievous wrong and lasting mischief. It were ill for us were there no surer and more perfect standard of rectitude than one subject to such accidents as this.

We must go somewhat deeper into the subject in order to find such a solution of the problem now before us as will abide the test. Happily the conclusion to which our previous speculations have conducted us, opens the way for such a solution.

If the ground and basis of rectitude be found in the Divine essence, it will follow that the character of God,—that is, the combined perfections of Deity as a manifested personality,—must form an absolutely perfect expression of moral excellence. God exists in the universe as He is in Himself; the outer manifestation is the efflux and interpreter of the inner glory. What we call his attributes are not qualities assumed by Him, or capable of being severed from Him or modified in Him; they are simply partial representations to our minds of that infinite and unchanging essence which we can never fully comprehend.⁴ In the revealed character of God, then, must be found the highest standard of moral truth for all his intelligent creatures; and the supreme aim of all of them, who would excel in goodness, must be to imitate God, to act so as that their characters shall resemble his. Hence we are commanded in Scripture to be "imitators of God" (*μιμηταὶ τοῦ Θεοῦ*), and to be holy according to the pattern or example of God; and the consummation of our regenerated being is set forth as consisting in our being made perfect in his likeness, changed into his image.⁵ Even Plato assures us that the only escape from the present evil state is by assimilating ourselves to God as much as may be—to God, who is absolutely and ever righteous, and whom none so much resembles as the man who becomes most righteous;⁶ and he points us to heaven as the place where alone the perfect paradigm of a State can be sought by him who would see it, and seeing it would inhabit it.⁷

But the character of God can be apprehended by us only as it is manifested to us. No man can by searching find out God. To be known by His creatures, the Infinite and Eternal must reveal Himself to them. Now, God has so revealed Himself to us. All that He does within the sphere of the sensible universe is a revelation of Him; on all that comes from Him he stamps the impress of His name. Hence creation in all its parts,—the constitution and order of nature, and the course of events, as controlled and regulated by His providence,—all, so far as they lie within our ken, supply us with information respecting the character of God. But in addition to these the world possesses a revelation of God in which He has clothed the truth concerning Himself in written words; and this He has placed before us as the fullest, clearest, and most instructive source of intelligence we can resort to on this sublime and all-important theme.⁸ From these sources may be gathered that supreme law, conformity to which is practical rectitude.

SECT. V.—HOW A KNOWLEDGE OF RECTITUDE IS ACQUIRED.

It may be asked, however, By what process does man, in point of fact, come to be acquainted with the intimations of these standards of moral decision? In reply to this, it may be said that it is by listening to the lessons of *experience*

¹ *De Repub.*, p. 508, E.; in Stallbaum's edition, vol. iii., pt. 2, p. 81.

² Οὐ γὰρ ἐστὶν εὐρεῖν τῆς δικαιοσύνης ἄλλην ἀρχὴν, οὐδ' ἄλλην γένεσιν, ἢ τὴν ἐκ τοῦ Διὸς, καὶ τὴν ἐκ τῆς κοινῆς φύσεως· ἐνταῦθεν γὰρ δεῖ πᾶν τὸ τοιοῦτον τὴν ἀρχὴν ἔχειν, εἰ μέλλομεν τι εἶναι περὶ ἀγαθῶν καὶ κακῶν. (Plutarch, *De Stoicor. Repugnantis*, Works, vol. vi., p. 55.)

³ "Attributa Divina in se ac per se considerata sunt realiter et simplicissime unum cum divina essentia." (Gerhard, *Loc. Theol.* ii., c. 7). "Sunt attributa [Dei] nihil aliud quam conceptus essentiae divinae inadæquati, ex parte rei ipsam essentiam involventes, eandemque intrinsece denominantes." (Quenstedt, *Theologia Didac. Polém.* i. 284.)

⁴ Compare Eph. v. 1, 1 Pet. i. 15, 1 Cor. xv. 49, 2 Cor. iii. 18, 1 John iii. 2.

⁵ *Theotes.*, p. 176, B. C.; in the edition of Stallbaum, vol. viii., pp. 170, 171.

⁶ *De Repub.*, b. ix., p. 592, B.; in Stallbaum, vol. iii., pt. 2, p. 295.

⁷ In this respect we may truly say of the Bible what Aristophanes says of some philosophical treatise much in vogue in his day:—

BIBAION τ' ἔχων ἑκάστος μανθάνει τὰ δεξιὰ. (*Frogs*, l. 1079.)

⁸ *De Legibus*, b. ii., c. iv., v.

Virtue. and correcting and enlarging these by regard to the teachings of *tradition* and *Holy Scripture*, that a thorough moral discipline may be best pursued. Each man's own experience will teach him that he lives in a world of which rectitude is the law; for he cannot but perceive that whatever departures men may make from this, every such departure is contrary to the primary order of things, is felt to be blameworthy even by those who make it, and is usually followed by such consequences as show that it cannot be done with impunity. What personal experience thus teaches, intercourse with other men, whose experience is found to be the same, confirms; and the concurrent testimony of past ages embodied in tradition, at once strengthens his own convictions, and corrects the mistakes into which a too partial induction may have betrayed him. And, in fine, when he is privileged to have the Holy Scriptures, he finds in them a law written which is the counterpart of the law written in the order of nature and on his own heart,

and which at the same time completes and corrects the moral beliefs which nature, conscience, and testimony, have already instilled into him. Virtue.

SECT. VI.—WHENCE THE CONCEPT OF RIGHT.

There is still another question which may be asked at this stage: Assuming that the basis of rectitude is discovered by a process of reasoning, and that the decisions of the standard of rectitude are ascertained by the same process, to what do we owe the original concept of right? Is this a simple or a complex notion? and do we arrive at it by a process of reasoning, or is it given to us by an inner revelation? These questions belong rather to Psychology than to Ethics. We shall therefore content ourselves with simply saying, that we incline to the opinion of those who regard this as a simple concept, incapable of analysis, and found in the mind as inseparable from its constitution.

PART II.—OF VIRTUE.

SECT. I.—VIRTUE DEFINED.

Virtue in individuals may be viewed under a subjective and under an objective aspect.

1. Virtue, viewed subjectively, may be described in the general as the harmony of the active with the moral nature of man. Virtue presupposes an agent of whom alone it can be properly predicated; for though we sometimes ascribe virtue to actions, this is only by an impropriety of speech akin to such metonymies as "a spirited action," "a manly career," &c.: virtue properly belongs to an agent—"appellata est enim ex viro virtus," says Cicero;¹ and it is conditioned by this that the emotional or conative energies of the agent shall be in accordance with his moral nature. Viewed as a mental state, virtue is this internal harmony in itself; viewed as an attribute of character, virtue is the habit of living to which this harmony leads, and by which it is exemplified.

Obs. Aristotle lays emphasis on the position that virtue is exclusively a *ἕξις* or *habit*, and cannot be ranked as either one of the capabilities (*δυνάμεις*) or one of the passions (*πάθη*) of our nature. By the former of these Aristotle means that part of our natural constitution by which we are capable of certain emotions; and by the latter he means the emotions themselves. Now, for neither of these in themselves, he argues, are we pronounced virtuous, but only for the due and proper exercise of them. But this presumes a deliberative choice, by which we regulate the indulgence of our desires and emotions, and by consequence our actions. Virtue, therefore, he defines to be *ἕξις προαιρετική*, a habit predetermined or fore-chosen, the object of which is our affections and actions. When, consequently, man chooses as he ought, *i.e.*, in accordance with his moral nature, virtue is the result.²

Plutarch teaches the same doctrine,—“Moral character (*ἦθος*) is the quality of the impulsive part of our nature;³ and it is so called because this quality, and the difference (=this differential quality), the impulsive part of our nature receives by custom (*ἔθος*); being moulded by the reason, which does not seek wholly to obliterate the passion (a thing neither possible nor desirable), but prescribes a

certain limit and order to it, and effects the ethical virtues; these being not passionless, but the due measures and means (*μεσότητες*) of the passions. Now it effects these by constituting, through prudence, the susceptibility of the pathetic (or emotional) in our nature into a gracious habit (*ἕξις ἀρετῆς*): for they say there are three things appertaining to the soul—capability, passion, habit; of which *capability* is the beginning and material of passion—as, for instance, capability of anger, of shame, or of bravery; *passion* is the moving of the capability,—as anger, shame, bravery; and *habit* is the strength and structure of the impulsive capability, produced by custom, and which is vice or virtue according as the passion is ill or well tutored by reason.”⁴ To the same effect, in another of his writings, he speaks of virtue as “that best and most divine habit in us which we cognise as the rectitude of reason, the summit of the rational nature, and the acknowledged congruity of the soul.”⁵

“Est virtus,” says Cicero, “nihil aliud quam in se perfecta et ad summum perducta natura.”⁶ “Quando virtus est affectio animi constans conveniensque ex ea proficiuntur honestæ voluntates, sententiæ, actiones, omnisque recta ratio; quamquam ipsa virtus brevissime recta ratio dici potest.”⁷

2. The active nature of man comprises his various appetites, desires, and passions. These have been denominated his *active* powers, because it is by them that he is impelled to action; but it would be better to term them conative energies: *energies*, because they are all mental forces,⁸ and conative, because what is common to them all is the *conation*, or effort to reach their object. Each of these has its own proper object, on which it terminates, and which it strives to attain; and though this striving may not always result in action, no action takes place without it. A mere perception, conception, or conviction, will never lead to action except as it awakens some appetite, desire, or passion.

3. The moral nature of man is summed up in the word *conscience*. Moral nature and conscience are two names of the same thing. The analysis of conscience, therefore, will unfold man's moral nature.

4. Conscience is a term describing a complex state of mind, which may be resolved into the following elements:

¹ *Tusc. Quæst.*, b. ii., c. 18. The Greek word *ἀρετή*, from *ἀρεω*, has a wider signification; it expresses the idea of *fitness*, *ability*, and hence is used of inanimate objects as well as of men. The German *tugend*, from *taugen*, *tügen*, exactly corresponds to the Greek; *tugend*=*tauglichkeit*, =fitness, ability. The Latin *virtus* has its etymological cognate in the Gothic *waitrths*, the German *werth*, and the English *worth*.

² See *Nicom. Eth.*, b. ii., c. iv. and vi.

³ *πείσους τοῦ ἀλόγου*. In what sense *πείσους* is to be taken here, the following explanation of Aristotle's third category will show:—“*πείσους* = adjectivum quo quale quid sit significatur.” (Trendelenburg, *Elementa Logices Aristotel.*, p. 53.) What Plutarch intends by *πείσους* will be best gathered from his own writings. Take the following instances:—*εἰς τὸ ἀλόγον καὶ φυσικὸν τῆς ψυχῆς*. (*Symposiaco*, 706, F.) *τὸ δὲ ἀλόγον καὶ παθητικὸν (τῆς ψυχῆς)*. (*De Amic. et Adulter.* 61, D.) See Paris ed. of Stephen's *Thesaurus*, under *ἀλόγος*.

⁴ *De Virtute Morali*, c. iv., p. 211, of vol. iii. of the Tauchnitz ed. of his Moral Works.

⁵ *De Audiend. Poetis*, c. vi., Mor. Works, vol. i., p. 56.

⁶ *Tusc. Quæst.*, b. iv., c. xv.

⁷ *De Legibus*, b. i., c. viii.

⁸ “Occulta vis dicitur *hýmnus* velut in semine, et *vis mentis* in homine.” (Erasmus on Rom. vii. 5.) In illustration of this may be cited Alexander the Aphrodisian, who, in reference to conception, says, “*ἄνεργος κατὰ τὰς αἰσθήσεις ἐνεργὼν φαντασίας λαμβάνει*.” (*De Animo*, b. i.)

Virtue.

(i.) A sense of the difference between right and wrong. Whence this arises it does not fall upon us here to inquire. It is sufficient that we signalize the fact that such a sense is common to men.

(ii.) A feeling of approval for what is right, and disapproval for what is wrong. This is a natural emotion implanted in us as part of our psychical constitution; and, like all our natural emotions, it is called into action immediately and directly on the presentation of its proper object. We commend what appears to us right, and we turn with censure from what appears to us wrong; just as we are drawn towards a beautiful object, or are repelled by one that is ugly; or as an object that pleases our palate is desired by us, while one that creates nausea is avoided. It is not implied in this that an action *is* right because it excites in those who witness it a feeling of approbation,—a doctrine which we have already sought to confute; on the contrary, we maintain that the existence of this feeling in the mind presupposes a perception or sense of the rectitude of the action, and thus implicitly assumes a standard and basis of rectitude distinct from and anterior to the emotion. Of the reality and speciality of the emotion itself every one may judge who will consider for a moment the difference between the feelings with which he regards the successful prosecution of a piece of reasoning, and the feelings that spring up within him when he contemplates a generous or righteous course of conduct: the former are those of admiration and assent yielded to the intellectual vigour or logical exactness of the reasoning; the latter are those of moral approbation called forth by the moral excellence—the rectitude and goodness of the action. It is this which the older writers had in view when they spoke of “the beauty of virtue,” of “the symmetry of virtue,” of “moral beauty,” and such like expressions; they intended thereby to convey the idea that virtuous actions are such as excite in the mind feelings of complacency and commendation analogous to those which objects of physical beauty awaken. “Of those things,” says Cicero, “which are perceived by sight, no other animal [but man] perceives the beauty, the grace, the accordance of parts; and nature and reason, transferring this analogy from the eyes to the mind, judge that much more are beauty, harmony, and order to be preserved in counsels and deeds, and guard against aught being done unbecomingly or feebly; moreover, in all opinions and acts, against aught being done or thought lustfully. Whence is collected and formed that which we seek, the proper (*honestum*); which, even though it be not celebrated, is still the proper, and of which we may truly say that even though lauded by no one it is laudable by nature.”¹ “The mind,” says Shaftesbury, “which is spectator or auditor of other minds, cannot be without its eye and ear; so far as to discern proportion, distinguish sound, and scan each sentiment or thought which comes before it. It can let nothing escape its censure. It feels the soft and harsh, the agreeable and disagreeable, in the affections; and finds a foul and fair, a harmonious and a dissonant, as really and truly here as in any musical numbers, or in the outward forms and representations of sensible things. Nor can it withhold its admiration and ecstasy, its aversion and scorn, any more in what relates to one than to the other of these subjects; so that to deny the common and natural sense of a sublime and beautiful in things will appear an affectation merely to any one who considers duly of this affair.”² To these quotations may be added the following from one of the least fanciful of thinkers—Edwards:—“Virtue is the beauty of those qualities and acts of the mind that are of a moral nature, *i.e.*, such as are attended with desert, or

worthiness of praise or blame. Things of this sort, it is generally agreed, so far as I know, do not belong merely to speculation, but to the *disposition* and *will*; or (to use a general word, I suppose commonly well understood) to the *heart*. Therefore I suppose I shall not depart from the common opinion when I say that virtue is the beauty of the qualities and exercises of the heart, or those actions that proceed from them.”³

(iii.) By this adaptation of our nature to be affected with complacency on the recognition of virtue, and with the opposite on the perception of vice, we are led to approve or blame ourselves according as we act virtuously or viciously, or rather according as *we believe* ourselves so to act, for it is our judgment of the moral qualities of actions, and not these moral qualities themselves, by which our feelings are determined. In this commendation or censure, however, does not consist the *whole* of what we feel in such cases. Besides the perception of the moral character of the act, there is also a sense of *responsibility* attaching to man as a moral agent; and besides the moral approbation or disapprobation which actions excite, there is an ascription of *merit* or *demerit* to the agent according as his actions appear to us good or bad. Responsibility or answerableness has respect to our being under government; it implies that we are subject to laws, and that if we transgress these laws a certain penalty shall be incurred by us; and as connected with moral conduct, it has respect to our being under the moral government of God, and amenable to his justice for the manner in which we act. Under the influence of this conviction we come to regard ourselves not only as objects of moral approval, or the opposite, but as having attached to us the quality of good or of ill desert. When we review our conduct, we feel constrained to believe either that we are able to meet the scrutiny of our moral governor, or that we are deserving of punishment because of our transgressions of his law. In the latter case, the painful emotions we experience may be so violent as to constitute that sense of remorse which is itself one of the severest punishments of guilt.

In the operations of conscience this last element is the one which comes most distinctly into consciousness. The sense of responsibility, and of consequent good or ill desert, is inseparable from the human mind; and though means may be used by the guilty to blunt or quiet it, these avail only for the time, and the painful consciousness seeks its opportunity of returning with augmented pungency. The lessons which are constantly read to us by the phenomena of event around us, as to the retribution which, even in this world, treads upon the heels of sin, are of themselves sufficient to quicken and sustain this sense within us. As in the physical world we cannot violate or neglect law without suffering for it, so we find in the moral world that an analogous arrangement obtains. There is perhaps no man who has not had many painful illustrations of this in his own experience, as well as in what he has observed of the history of others. Hence a universal conviction pervades the race that a man’s sin “will find him out”—that however he may conceal it from his fellow-men, so as to escape their censure or punishment, there is an Intelligence he cannot evade, a retributory Power he cannot escape; and that of all sin, however pleasant it may seem in the commission, it may be said that at the last “it biteth like a serpent and stingeth like an adder.”⁴ The impassioned utterance which the tragic poet has put into the mouth of one of his characters, expresses what the deepest convictions of the race respond to:—

Virtue.

⁴ Prov. xxiii. 32.

Virtue.

Zeῦ, Zeῦ κἀτάωθεν¹ἀποπέμπων ὑπερόποιον
ἄταν βροτῶν τλήμονι καὶ πανούργῳ
χείρῃ.¹

In consequence of the predominance of this element in the operations of conscience, some writers have contended that this is conscience, and so have identified the latter with the emotion of remorse. On the other hand, some, arguing that this emotion is a mere consequent on the judgment pronounced by man on the rectitude or wrongness of his own conduct, have resolved the act of conscience wholly into the judgment so pronounced, thereby identifying conscience with the purely intellectual faculty of judging. The truth, however, seems to be, that neither by itself completes the analysis of this complex state of mind. The emotion presupposes the judgment, and the judgment is followed or attended by the emotion; and both together constitute the main elements of conscience. With this accords the common popular usage of the term. We speak of a man's having a good conscience or a bad conscience, meaning thereby that, on looking back over his past conduct, he finds occasion either for self-commendation or self-blame, and either hopes for reward or dreads punishment, according as his conduct has been in conformity with, or opposed to, the standard of rectitude.

5. Now, according to the constitution of our nature, this moral faculty or conscience is the supremely-regulative power within us, and ought to control all the conative energies of our nature. When this takes place there is harmony between these two departments, and the consequence is a state of subjective virtue within the man; the entire system acknowledges and obeys its master-power, a just equipoise is preserved in all parts, and the whole moves easily and in order. On the contrary, when the appetites, emotions, and passions escape from this their proper control, there is a schism in the soul, order and propriety are disturbed, and vicious courses and habits usurp predominance in the life. It is possible, indeed, for the conflict between conscience and passion to become imperceptible, conscience being gradually suppressed and benumbed until it shall ultimately become wholly dormant, or, in the striking language of Scripture, "seared as with a red-hot iron;" but until this terrible consummation of depravity is reached, the conflict between the lower and higher powers of man's nature continues, and the schism within is perpetuated. Berkeley has graphically delineated the course of such an one in describing the English rake. "He is (as Aristotle expresseth it) at variance with himself. He is neither brute enough to enjoy his appetites, nor man enough to govern them. He knows and feels that what he pursues is not his true good; his reflection serving only to show him that misery which his habitual sloth and indolence will not suffer him to remedy. At length, being grown odious to himself, and abhorring his own company, he runs into every idle assembly, not from hopes of pleasure, but merely to respite the pain of his own mind. Listless and uneasy at the present, he hath no delight in reflecting on what is past, or in the prospect of anything to come. This man of pleasure, when, after a wretched scene of vanity and woe, his animal nature is worn to the stumps, wishes and dreads death by turns, and is sick of living without having ever tried or known the true life of man."²

6. Virtue, viewed objectively, is the accordance of the moral nature with the standard of rectitude. It has been already observed that we approve our conduct according as we believe ourselves to act rightly. But this belief may be founded on an erroneous estimate of what is right; and therefore, though there may be a state of subjective harmony in consequence of this belief, the man nevertheless cannot be pronounced virtuous in the full sense of the term. A truly virtuous man is one who not only walks according to conscience, but whose conscience is guided in its decisions and impulses by the dictates of the "perfect law."³

Virtue.

SECT. II.—CONDITIONS OF VIRTUE.

Aristotle has, with his usual pregnant brevity, set forth the conditions of virtue thus: "In reference to virtues, it is not enough that a thing be anyhow done so as to be justly or wisely done,—it is necessary also that the agent be in a certain way affected; *first*, he must have knowledge; *second*, he must choose, and choose for the thing's own sake; and, *third*, he must act with firm and inflexible purpose."⁴ In this passage he specifies as the conditions of virtue,—1. Knowledge; 2. Freedom of choice; 3. Choice determined by regard to virtue itself; and, 4. Stedfastness and firmness of resolution. Of these the last may be discounted as being accidental rather than essential. There remain,—

1. *Knowledge*.—This includes both the capacity of moral judging and acquaintance with the standard of rectitude. Both are essential conditions of all virtuous action. A man might stumble into the path of rectitude without either; but without the former he would be incapable of understanding what rectitude is; and without the latter he would have no sure means of ascertaining whether the path he was in was that of rectitude or not. Virtue is reached only when the agent is capable of apprehending moral distinctions, and determining the rectitude of actions by a just standard.

2. *Liberty of Choice*.—This implies that the agent is free to choose such paths as seem best to him, and that he exercises this freedom. It is no part of our present object to attempt to solve the metaphysical difficulties which surround the question of the freedom of the human will; all that it concerns us here to do is to assert the fact that man is a free agent; and to maintain that without the exercise of this freedom there is no such thing as virtue or its opposite. Let a man do the best deeds in the world or the worst, by accident or under physical constraint, and all will feel that neither praise in the one case, nor blame in the other, can be justly attached to him. It is the *choosing* to do the one or the other which constitutes the *conditio sine qua non* of virtue or vice.⁵

Obs.—"Now, since the end is the object of will, and since things having respect to the end are willed and chosen, it follows, that actions relating to these must be by choice, and voluntary; but the energies of the virtues are relating to these; hence virtue is in our power, and so is vice. For in respect of these it is in our power to act; it is also in our power not to act. . . . Some say that 'no man is willingly bad or unwillingly happy.' The former position is false, the latter true. No one is unwillingly happy, but wickedness is with the will. Else all we have above said must be repudiated; and it must be denied that man is a source (*ἀρχὴν*) and parent of actions as he is of children. If, however, this be ad-

Virtue.

mitted, and we have not to refer to other sources than those in our power, it follows that the things of which the sources are in us are also in our power, and objects of volition. To this both the private conduct of individuals and the conduct of legislators bear witness, for they punish and chastise those who do evil, provided they have not done it by force or through ignorance, of which they were not themselves the cause; whilst they reward those who do good. This they do with a view to stimulate the latter, and to deter the former; but no one is stimulated to what is not in our own power, or an object of volition. Thus, nothing would be more absurd than to persuade men not to be warm, or to grieve, or to be hungry, or such like, for not the less should we endure these." (Aristotle, *Nic. Eth.*, b. iii., c. iv. [vii]).

"Voluntas igitur nostra nec voluntas esset, nisi esset in nostra potestate. Porro quia est in potestate, libera est nobis. Non enim est nobis liberum quod in potestate non habemus, aut potest non esse quod habemus, nec voluntas esse potest si in potestate non est." (Augustine, *De Libero Arbitrio*, b. ii., c. 3.) "Semper est in nobis voluntas libera, sed non semper est bona." (The same, *De Gratia et Lib. Arb.*, c. 15.)

3. *Choice of the right for its own sake.*—The choice is determined by motives—a motive being, as the Greeks called it, τὸ ἐνεκα οὗ—that on account of which anything is chosen. Now one may choose the right from various motives. It may be chosen because it is the more convenient, or because it is the more agreeable, or because it is the more profitable course; or simply because it is the right course. It is only in the last of these cases that virtue can be predicated of the individual. It is not what is done that measures the virtue of the doer, but the intention with which it is done; "non quid fiat, aut quid detur, refert, sed qua mente."¹ Good actions done, therefore, without a distinct purpose to do good, are destitute of the quality by which alone they could reflect merit on the agent, or entitle him to be called virtuous.

SECT. III.—PRINCIPLE OF VIRTUE.

But if men can be virtuous only by acting with an intention to be so, they must live under the constant influence of an active principle of virtue operating within them. We have therefore to inquire what this principle is.

We may pass over such answers to this inquiry as those which make the love of pleasure, the desire of praise, or the sense of honour, the principle of virtuous action.² We shall notice—

1. That which places the principle of virtue in *benevolence* or *love to being in general*. This opinion has been ably advocated by the eminent American theologian and metaphysician Jonathan Edwards. According to him, "true virtue most essentially consists in benevolence to being in general; or, perhaps, to speak more accurately, it is that consent, propensity, and union of heart to being in general that is immediately exercised in a general good-will;" and in another place, he says, "That temper or disposition of heart, that consent, union, or propensity of mind to being in general, is virtue truly so called; or, in other words, true grace or real holiness. And no other disposition or affection but this is of the nature of true virtue."³ This benevolence to being in general—which the author distinctly and consistently states to be irrespective of moral character, for it "does not necessarily presuppose beauty in its object," and so has nothing of the nature of complacency in it—does not exclude particular affections; on the contrary, whilst it inclines to the highest general good, it inclines also "to each being whose welfare is consistent with the highest general good, in proportion to the degree of existence, other things being equal." The degree of existence,—that is, as defined by the author, "the having every faculty and every positive quality in a higher [or lower] degree,"⁴—

Virtue.

furnishes the *primary* ground of benevolence; a *secondary* is supplied by the existence of "virtuous benevolence itself in its object," and in this case esteem, complacency, and good-will, arise in the mind towards the being. It follows from this, that virtuous benevolence being determined in its degree, primarily, by the degree of existence in its object, and, secondarily, by the moral excellence of its object, virtue must consist in supreme love to God—who, on both grounds, infinitely surpasses all other beings—and in love to his creatures, according to the degree of existence and the moral excellence of each.

Of the most serious objections to which this theory is exposed, a condensed statement has been presented in such clear and felicitous language by the Rev. Robert Hall, that we cannot do better than extract the passage:—

"1. Virtue, on these principles, is an utter impossibility: for the system of being, comprehending the great Supreme, is infinite; and, therefore, to maintain the proper proportion, the force of particular attachment must be infinitely less than the passion for the general good; but the limits of the human mind are not capable of any emotion so infinitely different in degree. 2. Since our views of the extent of the universe are capable of perpetual enlargement, admitting the sum of existence is ever the same, we must return back at each step, to diminish the strength of particular affections, or they will become disproportionate; and consequently, on these principles, vicious; so that the balance must be continually fluctuating, by the weights being taken out of one scale and put into the other. 3. If virtue consist exclusively in love to being in general, or attachment to the general good, the particular affections are, to every purpose of virtue, useless, and even pernicious; for their immediate, nay, their necessary tendency is to attract to their objects a proportion of attention which far exceeds their comparative value in the general scale. To allege that the general good is promoted by them, will be of no advantage to the defence of this system, but the contrary, by confessing that a greater sum of happiness is attained by a deviation from than by an adherence to its principles; unless its advocates mean by the love of being in general the same thing as the private affections, which is to confound all the distinctions of language, as well as all the operations of mind. Let it be remembered, we have no dispute respecting what is the ultimate end of virtue, which is allowed on both sides to be the greatest sum of happiness in the universe. The question is merely, What is virtue itself? or, in other words, What are the means appointed for the attainment of that end?"⁵

It may be added to these admirable strictures that the system of Edwards virtually abrogates the moral sentiments in man, by leaving no place for complacency in what is morally good and lovely. For what is his secondary ground of virtuous benevolence, on which alone he professes to find space for a love of complacency? It is the perception of "virtuous benevolence itself in its object." This, according to him, is "the beauty of the being in whom it is," and it is the seeing of this alone which awakens esteem or complacency towards that being. But wherein does this essentially differ from benevolence to being in general, which, according to Edwards, has no respect to character? If the only thing which awakens complacency be the perception in another of benevolence to being in general, what is the object of that complacency but this benevolence? Edwards himself admits that it is. "Loving a being on this ground," he says, "necessarily arises from pure benevolence to being in general, and comes to the same thing." But if so, the only thing in which we have complacency,

Virtue.

morally speaking, is a thing totally irrespective of moral character. In this case what place is left for the moral sentiments? or what is approbation of goodness but merely a modified form of a feeling which has nothing to do with goodness?¹

2. Closely allied with Edwards's theory is that which resolves all virtue into love to God. This theory is as old as Augustine, who has in many parts of his writings dwelt upon this theme. From some scores of passages which might be cited we select the following, because of its fullness:—"Now, if virtue lead us to the blessed life, I would affirm that virtue is nothing else than supreme love of God. For, so far as I perceive, that which is called the four-fold virtue is named from the varying affection of love. Hence I should not hesitate to define those four virtues—of which I would that the power were as much in the minds as the names are in the mouths of men!—in such a way as that *temperance* should be love proffering itself entire to the object loved; *fortitude*, love easily enduring all things for the sake of the object loved; *justice*, love serving only the object loved, and therefore rightly ruling; *prudence*, love selecting wisely those things by which it may be aided from those by which it may be hindered. But this love we have said is not of any one, but only of God; that is, the chief good, the chief wisdom, the chief concord."² There is no great difference between this and what Edwards states when he says, "He that has true virtue . . . must necessarily have a supreme love to God both of benevolence and complacency. And all true virtue must radically and essentially, and as it were summarily, consist in this. Because God is not only infinitely greater and more excellent than all other beings, but He is the head of the universal system of existence; the foundation and fountain of all being and all beauty; from whom all is perfectly derived, and on whom all is most absolutely and perfectly dependent; and of whom and through whom and to whom is all being and all perfection; and whose being and beauty are, as it were, the sum and comprehension of all existence and excellence, much more than the sun is the fountain and summary comprehension of all the light and brightness of the day."³

In proceeding to remark upon this theory it may be necessary to premise, that no question is here raised as to the supreme moral excellence of love to God, as to the obligation resting on all his intelligent creatures to love Him supremely, or as to the nullity of all virtue which does not include love to God as its crowning and controlling element. Our only question is, Does this constitute *all* virtue? Is there no moral excellence but what is immediately resolvable into love to God?

And here it occurs first of all to ask, What, on this theory, constitutes the moral excellence of God himself? There are some who would not scruple to answer, "His love of Himself;" and, rightly understood, the answer is unimpeachable; for the highest conception we can form of God is that of a being who finds in his own perfections the object of his eternal and unmixed delight, and all whose manifestations and workings are for his own glory. But it may be questioned whether this is properly called *love to*

God. Is it not rather God's delight in moral goodness, which has its fountain-spring in his own eternal essence, and is enstamped on everything that He calls into being?

Virtue.

Descending to man, it is obvious to remark that, as used of him, "Love to God" is a phrase of ambiguous meaning. It may mean one of three things,—delight in God's holy character,—gratitude to God for his goodness,—and a desire for the Divine honour, or a rejoicing in the Divine felicity. Now, in which of these senses is the phrase used when it is said that all human virtue consists in love to God? If we take it in the last of the three, the theory coincides with that of Edwards, for love to God in this case is just benevolence directed towards Him as the greatest of beings, without respect to his goodness. If we take it in the second of the three, the theory resolves itself into the assertion, that all virtue consists in gratitude to God for blessings received; and if we take it in the first of the three, the theory is equivalent to that which affirms virtue to consist in the love of goodness for its own sake. Of these theories the first two must be rejected as inadequate, for there are surely many virtues which cannot be resolved into either a desire for the Divine felicity and glory or a feeling of gratitude to God for his goodness; indeed, to go no farther, neither of these will resolve into the other, and yet both are virtues demanded of man. The last of these theories we hold to be the true one; but we object to designating it by the phraseology now under consideration.

3. There is a theory which, borrowing from Edwards the latter part of his doctrine, resolves all virtue into general benevolence, or benevolence to the race at large. Of this theory it is part to depreciate the domestic affections, or particular affections of any kind, and to teach that the truly virtuous man is one who cultivates a cosmopolitan benevolence, and merges all claims upon his love in one common sentiment of universal philanthropy. On this theory it may suffice to observe, briefly—(1.) That it is essentially *atheistical*, inasmuch as in the scheme of moral duties to which a virtuous man is bound, it finds no place for those he owes to God; the existence of God is ignored, and a phantom god, in the shape of humanity or the race, put in his stead. (2.) This theory is opposed by the testimony of consciousness, which tells that we *have* particular affections, that these are called into constant action within us, and that in no case do they arise from any consideration of the general weal, but are awakened each by its own special object in consequence of certain relations existing between us and it. (3.) This theory impeaches the wisdom of that part of our constitution which provides, for our affections being strongest when they are confined within the narrowest limits, whilst they become weak in proportion as we widen the circle and attempt to embrace within our regards the millions of the race. (4.) This theory reverses the order in which all experience teaches us that the benevolent affections are cultivated within our bosoms; for it is not by a descending process from the position of general philanthropy to the several spheres of patriotic, social, amical, and domestic affection, that we learn to love our fellow-men, but by a process the reverse of this—a process begun in the

¹ See some additional strictures on this theory in Dr Wardlaw's *Christian Ethics*, Lect. ix., and in Sir James Mackintosh's *Dissertation*. To the following remarks of the latter of these writers, however, we must demur:—"The justness of the compound proportion on which human virtue is made to depend is capable of being tried by an easy test. If we suppose the greatest of evil spirits to have a hundred times the bad passions of Marcus Aurelius, and at the same time a hundred times his faculties, or, in Edwards' language, a hundred times his quantity of being, it follows from this moral theory that we ought to esteem and love the devil exactly in the same degree as we esteem and love Marcus Aurelius." Now, to this an Edwardsian might reply, that it is doubly wrong,—1st, by not observing that mere quantity of being cannot excite *esteem*,—that being called forth only by *benevolent* being; and 2dly, by overlooking Edwards' qualifying clause, when, speaking of degrees of existence, he includes among the objects of pure benevolence *only* those "whose welfare is consistent with the highest general good." As the devil's wickedness excludes him from the secondary ground of benevolence, this qualifying condition excludes him from the primary. Let the "quantity of his being" be what it may, he can never be the object of benevolent love, any more than of complacent love, on Edwards' principles.

² *De Moribus Ecclesiae*, b. i., c. xv.; compare also c. xxii., c. xxiv., and c. xxv. See also his *Epist.* 52 *ad Macedonium*.

³ *Diss.*, c. ii.

Virtue. cradle, when the infant first responds to the tenderness of maternal endearment, and carried on through the successive stages of domestic and social life, until in favourable natures it at last reaches a universal philanthropy, which loves man as man, and yet reserves its fullest and tenderest affections for those to whom God and Nature have given the earliest and strongest claim. *In fine*, this theory is suicidal; for, by placing all virtue in universal benevolence, it secures that there shall be no benevolence at all. "When this savage philosophy," says Hall, "has completed its work,—when it has taught its disciple to look with perfect indifference on the offspring of his body and the wife of his bosom, to estrange himself from his friends, insult his benefactors, and silence the pleadings of gratitude and pity,—will he, by thus divesting himself of all that is human, be better prepared for the disinterested love of his species? Will he become a philanthropist only because he has ceased to be a man? Rather in this total exemption from all the feelings which humanize and soften,—in this chilling frost of universal indifference,—may we not be certain that selfishness, unmingled and uncontrolled, will assume the empire of his heart; and that under pretence of advancing the general good, an object to which the fancy may give innumerable shapes, he will be prepared for the violation of every duty and the perpetration of every crime?"¹

4. We have already indicated the theory to which we incline in reference to the present object of inquiry. The principle of virtue we take to be *love of rectitude and moral goodness for its own sake*—a love which partakes of the nature of reverence, and which acts upon the mind with a force that constrains to virtue. This love of goodness is, in the Divine Being, the moral perfection of his person,—the *δικαιοσύνη τοῦ θεοῦ*,—the perfect becomingness of God, whereby "He conforms Himself to his essence, and carries Himself so fitly to Himself, that no spot, no darkness, no shadow of turning, no indecency or irregularity can possibly happen to Him."² In man this love of goodness is a serene and profound complacency in that moral excellence which has its source in the Divine nature, and is embodied in the moral law—

"The justice
Of the unbribed, everlasting law."

And inasmuch as it is embodied in such a law, this justice or moral goodness cannot be loved without being also revered. As the mind contemplates it with delight, there is also suffused over the soul a sense of awe that forbids us to rest in mere contemplation, and prompts us to obey the law lest we incur its penalties. The principle of virtue thus coalesces with that of conscience, as above described.

SECT. IV.—OF MORAL OBLIGATION.

The conclusions at which we have arrived enable us to give a definite answer to the question, What is moral obligation? This is not a mere conviction of the reason; for though reason may guide, it never by itself constrains or obliges. Nor is it a mere feeling of admiration for, and delight in, what is morally good; for however pleasing this feeling may be, it of itself exerts no motive force upon us. Nor is it a mere sense that we *ought* to do what is right and good; for though this may act in the way of urging us to the paths of virtue, it falls short of the idea of obligation, inasmuch as it is popish to conceive the existence of a sense of owingness where there is no feeling of being under any obligation to render what is due. "Obligation," says War-

Virtue. burton, "necessarily implies an obliger, [who] must be different from, and not one and the same with, the obliged;"³ and to the same effect Paley says, "Obligation is nothing more than an inducement of sufficient strength, and resulting in some way from the command of another."⁴ What obliges us to virtue is the sense of being under moral law; it is reverence for moral law involving a dread of the consequences of transgressing it; it is the voice of conscience commanding rectitude, and whispering retribution to those who neglect or contravene it.

We are not disposed to go the length to which Warburton and some others (Paley, by implication, among them) have gone in denying the possibility of a sense of moral obligation, apart from the distinct dogmatic recognition of the Divine existence and government. Assuming the possibility of a man's being a sincere atheist, we could still conceive of such an one as having a deep reverence for what Fichte calls "the idea of moral order" in the universe, and a salutary dread of the consequences which he sees to flow from violations of that order. At the same time, it is the realization of the existence and rule of God as a moral governor which gives to the sense of obligation its greatest force, pungency, and constancy; nor, if it be true that the foundation of rectitude is to be sought in the essential nature of God, can we forbear to conclude that those who deny the existence of God have placed themselves where logical consistency would extort from them a denial also of moral distinctions. In accordance with this, it has ever been found that religion is the surest promoter of morals, and that it is only as men fear the Supreme Lawgiver that they are inclined steadily and conscientiously to act the part of good men and good citizens. "We have reason to believe," says Hooker, "that all true virtues are to honour true religion as their parent, and all well-ordered commonwealths to love her as their chiefest stay."⁵

OBS. 1. Some have distinguished between an *external* and an *internal* obligation; designating by the former that force of reason by which we are constrained to actions as in themselves good, and by the latter that constraint which issues from feeling that we are under the authority and law of God. (See Burlamaqui, *Juris Nat. Elementa*, p. i., c. vi.; p. ii., c. vii, sec. 13.) This distinction has its foundation in truth; for it is very certain that before we can feel any sense of moral constraint, we must not only know that a particular course is commanded, but feel that it is in itself good. On the other hand, however, it is quite possible to feel convinced that a course is good, and yet not feel any obligation to follow it. It seems better, therefore, to say that both form elements of the one complex conception of moral obligation. "Though sin and punishment are closely connected, yet the obligation of *non licet* (*it may not be done*), is distinct from the obligation of *non impune* (*not with impunity*), as sin and punishment are of distinct consideration. But a man is bound both when he cannot do a thing without sin, and when he cannot do a thing without punishment; and both these obligations are in every [divine] law, and both concur to make the obligation of it." (Appendix to Maxwell's translation of Cumberland *De Legibus Naturæ*, by the translator, p. 55.) The reader may compare the statements of the following writers on this subject:—Clarke, *Discourse*, p. 43; Warburton, *Div. Leg. of Moses*, vol. i., p. 93, 5th edition; Price, *Review*, &c., c. 6; Horsely, *Sermons*, vol. ii., p. 189; Stewart, *Active and Moral Powers*, vol. i., p. 293; Wardlaw, *Christian Ethics*, lec. 6.

OBS. 2. "The *Autonomy* of the will is the alone principle of all moral laws, and of their relative duties: all *Heteronomy* of the arbitrary will, on the other hand, not only founds no obligation, but is rather opposed to the principle thereof, and to the morality of the will. It is in the independence of all material of the law (that is, any desired object), and along with this the determination of the will by the simple general legislative form of which a maxim⁶ must be capable, that the alone principle of morality consists. That independence, however, is liberty in the *negative*, this self-legislat-

¹ *Modern Infidelity*, Works, vol. i., p. 54. To the advocates of this theory we may recommend the Terentian Chremes as an exquisite realization of their sublime morality. "Homo sum; humani nihil a me alienum puto," exclaims the universal philanthropist; and presently we find him scolding his wife because she had not, according to his orders, made away with their infant daughter.

² Polhill, *View of some Divine Truths*, c. iii.

³ *Mor. Philos.*, c. iii.

⁴ A maxim, in the Kantian phraseology, is, as defined by Kant himself, "the subjective principle of willing" (*Met. d. Sitten*, c. i.); or

⁵ *Divine Legation of Moses*, b. i., § 4.

⁶ *Eccles. Polity*, b. v., § 1.

Virtue.

ing of the pure and as such practical reason, is liberty in the *positive*, acceptance. Hence the moral law expresses nothing else than the autonomy of the pure practical reason, *i.e.*, of liberty, and this is itself the formal condition of all maxims under which they can alone coalesce with the superior practical law." (Kant, *Kr. d. Pr. Ver.*, b. i., c. 1, sec. 8.) If by this nothing more were meant than that an act to be binding must, whether prescribed by an outward law or not, be recognised by the mind as morally right, the doctrine of this passage would not differ from that above laid down. But by "the autonomy of the will" Kant meant that the will is its own law, and finds the reason of action, the categorical imperative, in itself. To this we confess we have always found it exceedingly difficult to attach any clear idea. It is easy to see how the reason, or the conscience, may be a law to the will; but how the will can be a law to itself we find it hard to conceive. Is not *autonomy*, in any strict sense of the term, a universal impossibility? How can one and the same power be at once above itself as lawgiver, and under itself as subject to law?

SECT. V.—PRINCIPLES CONCURRENT WITH THE PRINCIPLE OF VIRTUE.

In excluding all principles but the one specified, it is not intended to affirm that others besides it do not concur to animate and confirm virtuous activity. On the contrary, while we hold reverence for rectitude to be the alone principle of virtue, as such, we would carefully recognise others which concur with it, and aid it in directing the conduct of men. Of these, Mr Stewart has specified Decency, or a regard to character; Sympathy; a sense of the Ridiculous; and Taste, considered in its relation to morals.¹ Of these, the first and the last are the only ones that can pass unquestioned: a regard to character and a refined moral taste—a taste that cleaves instinctively to "the first good, first perfect, and first fair," in preference to all other objects, and which revolts from the grossness of vice, however outwardly adorned—are unquestionably principles that operate as auxiliaries to virtue; though even with regard to them it is necessary to give great prominence to Mr Stewart's qualifying condition, that "they maintain their due place in subordination to the moral faculty," and are not suffered to "prevail in the character as the leading motive to action." Of the other two he has specified, the claims to be reckoned among the auxiliaries of virtue are, we think, very doubtful. If the sense of the ridiculous was invariably, or even by a primary affection, excited by what is immoral, it might be regarded as intended to help us in the paths of virtue; but we suspect no analysis will show any natural relation between the two, and in point of fact we know that it is rather virtue than vice that is made the object of this sensibility. As for sympathy, it depends wholly on our previous moral character whether it shall aid or impede the course of virtue; for a bad man will sympathize with the bad just as readily as a good man will with the good, and perhaps with greater force. If instead of these we substitute such feelings as gratitude to God for his goodness, benevolence towards men, a love of what is useful for its own sake, we shall have principles, the operation of which no one can doubt to be eminently serviceable in strengthening the virtuous principle within us, and aiding to confirm us in all virtuous courses.

SECT. VI.—MEASURE OF VIRTUE.

Virtue.

As in Physics a motive force may be measured by the quantity of resistance it is competent to overcome, so in Morals the measure of virtue is found in the amount of resistance which the virtuous principle in an individual is able to surmount. A man who does right because he is never tempted to do wrong, shows less virtue, so far as this particular case is concerned, than the man who, though strongly tempted to turn aside from the path of rectitude, firmly adheres to it from sheer love of rectitude. And so, generally, in proportion as the inducements to evil are many and strong, is the degree of virtue which enables a man to resist them, to conquer them, and to pursue the good.

SECT. VII.—PRACTICAL RULE OF VIRTUE.

In the ordinary business of life it is impossible for men to stop to adjust every action by the absolute standard of rectitude, even when that is within their reach in an easily consultable form. The desirableness, consequently, of some compendious rule, which, if not scientifically exact, shall yet be sound so far as it goes, and shall supply readily a practical test by which actions may be tried, has been felt by all men, and various attempts have been made to supply it. Of these, none approaches in value to that which has received the sanction of the Author of Christianity, and which He thus enunciates: "Whatsoever ye would that men should do unto you, do ye even so unto them."² This rule is not peculiar to our Lord's teaching; heathen as well as Jewish moralists have before Him inculcated the same principle;³ but He has not only enunciated it more distinctly than any other; He has, by enunciating it, given it an authority which it would not otherwise have had. Than this rule no better could be suggested. It is alike simple and comprehensive; a rule for men in all circumstances, capable of being instantly and easily applied, and such as cannot be followed honestly and intelligently without exercising a most wholesome influence on the whole of a man's conduct. Of morality as embodied in this rule it may be justly said, "It is not hidden from thee, neither is it far off. . . . It is very nigh unto thee; in thy mouth and in thy heart, that thou mayest do it."⁴

OBS. Kant's rule, "Act so as if the maxims of thine acting should, through thy will, come to be general laws of nature" (*Met. d. Sitten*, c. 2, and in many other places of that treatise, and the *Kr. d. Pr. Vern.*), has been sometimes cited as if it were identical with the rule of Christ, only presented in a somewhat more scientific form. But the identity is in appearance only. Kant's rule is really the old Stoic rule, "Live conformably to nature;" for, if we are to act only so as that our subjective grounds of acting might become general laws of nature, it seems very plain that the general laws of nature are the norm or standard to which our subjective principles of acting must be conformed.

Fichte's rule, "Act always according to the best conviction of thy duty; or act according to thy conscience" (*Sittenlehre*, p. 195), is unimpeachably sound; but before it can be acted on, one must possess all that knowledge to compensate for the want of which, in whole or in part, a short practical rule is desiderated.

PART III.—OF DUTIES.

1. Our previous inquiries have possessed chiefly a speculative interest; we now turn to investigations of a practical kind. When we have determined wherein rectitude consists and what constitutes virtue, we are prepared for,

and urged upon, the question, What practical courses are right, and such as a virtuous man will pursue?

2. This question may be answered generally by affirming that a virtuous man will do his duty; or, what comes to the

as one of his disciples has explained it, "the practical rule which determines the free-will of any being." (Kiesewetter, *Darstellung der wichtigsten Wahrheiten der Kr. Phil.*, i. 160.)

¹ *Active and Moral Powers*, vol. i., p. 306.

³ Matt. vii. 12.

⁴ Deut. xxx. 11, 14.

Duties.

same thing substantially, will exemplify the practical virtues. This, however, leaves still open the question, What are the practical virtues? what are men's duties?

3. In answering this question we shall follow the method and classification most commonly adopted in this country,—that, viz., which arranges our duties according to our relations. This we prefer as the one which most naturally falls in with the tenor of our previous speculations, and at the same time affords the best scope for a clear and satisfactory discussion of the subject.

Obs. Of other methods we may notice the following:—

1. Some have taken the leading or cardinal virtues, and showed what is peculiar to each of them, and to what practical courses each of them tends. This is the course followed by most of the ancient ethicists, though declined by Aristotle.

2. Some have inquired whether all the virtues may not be generalized into one, of which the rest are the forms or manifestations; and having ascertained this, as they believe, have proceeded to show how all the practical duties of life flow out of this one magistral and reginal virtue. So Plato.

3. Some have arranged duties according to their relation to each other. With this view, some have distinguished between duties of perfect and duties of imperfect obligation,—a distinction recognised by the Stoics (see Cic. *De Fin.* iii. 7, 9, 17, 18; *De Off.* i. 3), and adopted by some modern writers; while others prefer distinguishing between determinate duties and indeterminate, or duties of primary and duties of secondary obligation. This latter distinction may be admitted as valid; but it comes to be of use chiefly as a guide in Casuistry, and cannot form an adequate basis of general classification.

4. Kant has adopted a somewhat complicated classification. He first divides duties into Duties of Right (*officia juris*), i.e., such as are capable of being prescribed by law; and Duties of Virtue (*officia virtutis* s. *ethica*), for which no such prescription is possible, and this because they are directed to an end, to attain which is equally a duty, and the contemplation of which is an inner act of the mind, so that it cannot be effected by any outward legislation. He then distinguishes between man viewed simply under the peculiarity of his faculty of freedom,—simply in his manhood, as a personality independent of physical conditions,—man as a *noumenon*, and man as a *phenomenon*, or as subject to these conditions, and affected by them; and in relation to this he distinguishes duty as it respects—(1.) The right of manhood in our own person, from (2.) The right of men; and (3.) The end of manhood in our own person, viz., our own perfection, from (4.) The end of men, viz., their happiness. Of these, 1 and 3 are duty to ourselves, 2 and 4 are duty towards others; and 1 and 2 are perfect duty, 3 and 4 imperfect. He distinguishes also according to the subjective relation of the binding and the bound, and concludes that there is no relation of right between man and a being that has neither rights nor duties, nor between man and a being that has simply duties and no rights, nor between man and a being that has simply rights and no duties. The only relation that can be subjected to formal law is that of man to a being who has both rights and duties.¹

5. Fichte has adopted a simpler classification. He distinguishes (1.) *Mediate and conditioned duties*, from *immediate and unconditioned or absolute*; meaning by the former, duties which terminate upon ourselves, and by the latter, duties which we owe to the universe; and (2.) *General from special duties*, denoting by the former, those which arise out of positions which cannot be conferred on men, and by the latter, those which arise out of positions that can. Combining these two distinctions, he divides his subject into general and special *conditioned* duties, and general and special *absolute* duties; and the latter more particularly into duties determined by one's natural condition, and duties determined by one's special vocation.² This classification has the merit of simplicity, but some of the distinctions on which it is based are of very questionable soundness. Why, for instance, should the one class be pronounced conditioned and the other absolute? The former, says Fichte, are conditioned because "they can be derived only through this position, that if the moral law wills the conditioned,—the realization of the mastery of Reason over me through me,—it wills also the condition that I be a fitting and adapted means to this end." But is not the duty I owe to others, in so far as it is due by me, conditioned by the same requirement, viz., that I am fitted and adapted to render it?

4. The relations which man sustains have been determined for him by God; and man enters upon them as part of the constitution of things under which he has to exist.

Duties.

In a sense, therefore, these relations are arbitrary; they are the result of the Divine volition and appointment. But in another sense they are not arbitrary; for God, in constituting things as they are, had reference to the inherent and essential attributes of his own nature, so that all the relations in which man finds himself placed are such as fall in with perfect rectitude, and such as could not but be if God was to create man at all. In like manner, the duties which flow out of these relations are fixed and necessary: having established the relations, God could not but make such and such duties to flow out of them.

5. Duty is a *debt* (*debitum*), something which we *owe* to some being. But we do not owe this to *all* being, nor even to all being of the existence of which we are aware; we do not owe anything, for instance, to *angels*, though we are assured of the fact of their existence: our duty begins where our relations begin; and it grows in extent and urgency as our relations become more numerous and close.

6. The correlative of Duty is Right. Wherever one person owes a duty to another, that other possesses a corresponding claim of right over the former. His claim is called a *right*, because wherever a duty is owing, rectitude dictates that it should be paid. It may be needful to remark in passing, that we are discoursing at present only of natural moral duties and rights, not such as may be created artificially by human legislation or arrangements.

7. The relations which man sustains are distributable into three classes: 1. Those which he sustains to himself; 2. Those which he sustains to his fellow-creatures; 3. Those which he sustains to God. Corresponding with these three classes of relations are the three classes of duties to which man is bound. These we now proceed to specify, though our limits forbid our entering into this part of our subject with any fulness.

SECT. I.—DUTIES WHICH MAN OWES TO HIMSELF.

At first sight it may appear as if something of a contradiction were involved in the assertion that a man owes duties to himself; for how, it may be asked, can a man be both giver and recipient in respect of one and the same object? or how can he be the holder of a right which binds, and the subject of a duty by which he is bound, in reference to one and the same thing? We may meet this difficulty by remarking, that man may be viewed under a two-fold aspect: either simply as a *phenomenon*—a concrete being existing in the world; or as a *noumenon*—a conceived personality endowed with freedom of will. In the latter capacity he is capable of being bound to duties; and it is this inner personality which is contemplated as so bound to the concrete phenomenal man, when we speak of man's owing duties to himself.³

Viewed in his aggregate existence, man may be regarded as 1. A being having life; 2. An intellectual being; and 3. A moral and religious being. In all these respects he owes duties to himself.

1. *As a being having life*, man owes it to himself to preserve and nourish the life he has received. For this purpose he must supply himself with necessary food, and clothing, and shelter; he must avoid whatever would injure his health, impair his strength, or shorten his life; and he must use means when his health has been injuriously affected to have it restored. This duty involves that of self-defence against the assault of another, even to the extent of taking the assailant's life should that be necessary for the preservation of our own. It also forbids self-murder, and all those practices, such as intemperance, debauchery, or excessive labour, which tend to shorten life.⁴

¹ *Rechtslehre und Tugendlehre*, in vol. ix. of his collected works, p. 43 ff., p. 245.

² See Kant, *Tugendlehre*, b. i., Einleit.

³ *System der Sittenlehre*, p. 326, ff.

⁴ Comp. Xenoph., *Memorabilia*, b. ii., c. i.

Duties.

2. As *an intellectual being*, man owes it to himself to cultivate his mental faculties, to store his mind with useful knowledge, and to endeavour constantly to regulate his opinions and conduct by the free and impartial exercise of his intellectual powers. The gift of intellect should be prized for its own sake as well as for the uses to which it may be put; and means should be wisely and steadfastly employed to effect a catholic development of all the mental faculties and susceptibilities. Hence the duty of being educated—a duty which is incumbent not only on children and young persons, but which should be felt as a constant duty, to be attended to by all through life, so long at least as mental vigour is continued.

3. As *a moral and religious being*, man owes it to himself to cultivate his moral susceptibilities, to accustom himself to attend promptly and faithfully to the dictates of conscience, and to seek so to educate conscience as that its dictates shall be in accordance with what is right and good. Without culture the moral powers become feeble, and are irregular in their action; whereas, by due cultivation they are strengthened and directed, and may be brought to control with a supreme but not offensive sway the whole conduct. As a moral being, further, man owes it to himself to abstain from the indulgence of all polluting, degrading, or demoralizing passions and pursuits. He owes it to himself to be chaste, not in act only, but in imagination and purpose; to be truthful even when no other person is to be injured by his indulging in falsehood; to be moderate in his desires, not giving way to covetousness, to ambition, or to a vain love of display; to be humble, not merely in relation to others, but within his own soul; and to avoid all indolence, sloth, and apathy. As a religious being, man owes it to himself to cultivate piety, to habituate himself to a constant acknowledgment of God, to be assiduous in all religious duties, and to make the attainment of God's favour and preparation for heaven the supreme objects of his life.

SECT. II.—DUTIES WHICH MAN OWES TO HIS FELLOW-CREATURES.

Of creatures to which man sustains relations there are only two classes, his fellow-men and the lower animals.

I. Beginning with the latter as the less important, the duties which man owes to the animal creation around him are either general or special. To all animals he owes benevolence, to the extent of the avoidance of whatever would give needless pain to any of them; not that he may not pursue them and kill them either to free himself from those that are noxious, or to supply himself with food and other necessities from those that are useful, but that in either case he is not to act cruelly by giving pain beyond what is necessary for the destruction of life. To those animals which he has domesticated man owes protection, provision, and all needful care to preserve them in health and vigour, as well as kindness in the treatment of them, not exacting of them more or severer labour than they can render, or subjecting them to pain and terror for mere amusement or for the sake of gain. All such barbarous amusements as bull-fights, bull-baiting, bear-baiting, dog-fighting, cock-fighting, are to be repudiated as *wicked*; and though some excuse may be pleaded for what are called field sports, on the ground that they promote health, keep down the numbers of noxious animals, or furnish a supply of food which could not be obtained in a way less painful to the animals slain, there can be no apology for such amusements as horse-racing and steeple-chasing, where a noble animal is subjected to “a pace that kills,” merely to afford idle men and women a little excitement, and unprincipled men and women an opportunity for gambling.

Duties.

II. The duties which man owes to his fellow-men are also either general or special; the former being such as he owes to all men indifferently, the latter such as he owes to those in peculiar circumstances, and those to whom he himself sustains special relations.

1. *Duties owing to our fellow-men generally*.—“God hath made of one blood all nations of men for to dwell on the face of the earth.”¹ This fact, for the knowledge of which we are indebted to the Bible, establishes a bond of relationship between all the members of the human race simply as such. Hence we owe to *all* men certain duties. These are—

(i.) *Goodwill*.—This implies not only the absence of all malevolent feelings towards others, such as envy, vindictiveness, malice, &c., and abstinence from all the acts to which such feelings lead, but also a propensity to be interested in the well-being of our fellow-men, and a readiness to do them good by the promotion of their bodily, their intellectual, their moral, and their eternal welfare. This is that *φιλανθρωπία* which the sacred writers ascribe to God (Tit. iii. 4), and which by various precepts they inculcate upon us.²

(ii.) *Respect*.—We are to “honour all men.” This does not mean that we are to render to all an equal tribute of approbation, for some men we are bound to condemn, and in general the degree of approbation which we bestow on men ought to be measured by the degree of their moral worth. The precept means that we are to recognise the worthiness that is in man as man, and to render him corresponding respect; not despising any because of adventitious circumstances, not treating any with discourtesy however lowly, and not regarding as outcasts or unworthy of our notice even the most abandoned and base. In man as man there is a worth and a dignity that make it the duty of every man to honour all men.

(iii.) *Truthfulness*.—We owe it to all men, in conveying to them knowledge concerning any person or thing, to communicate to them exactly such a conception of the fact as we ourselves have. That conception may not be physically true, *i.e.*, the thing as conceived by us may not answer exactly to the thing as it is; but if we convey to another our own conception of it, neither more nor less, all the requirements of moral truthfulness are satisfied thereby. This implies that neither by word, nor look, nor hint, nor act, do we lead another to think of the matter of communication otherwise than it really is as contemplated by our minds. This forbids—(1.) All intentional falsehood, *i.e.*, all communications by word or deed designed to convey to another a conviction which we *know* to be false in fact; (2.) All uttering as true what we do *not* know to be true, or as false what we do *not* know to be false; (3.) All prevarication and shuffling by which we may seek to *evade* the truth, and, without directly telling a lie, may virtually do so by leaving a false impression on the mind of another; (4.) All equivocation and mental reservation, *i.e.*, the use of words which have an ambiguous meaning, for the purpose of leading the party to whom we speak to understand them in the sense which we know not to be the one consistent with the fact, and the use of words which only express part of the truth, the rest being kept back so as to mislead those to whom we speak; and (5.) All exaggeration or extenuation, so as to convey to the mind of another a stronger or a weaker impression of the fact than we ourselves entertain. In all these respects the command, “Speak every man truth with his neighbour,” is binding upon us. It must, however, be kept in mind here, that it is the *intention* to deceive that constitutes a lie or gives guilt to falsehood; if the speaker is himself mistaken, or if he uses forms of speech which, though not corresponding exactly to the fact, are yet so understood as not to con-

¹ Acts xvii. 26.

² Comp. Matt. v. 33, 47, Lev. xix. 18, Jam. v. 9, Tit. iii. 3, Eph. iv. 31, Gal. vi. 10.

Duties. vey any wrong impression, he cannot be charged with having violated the duty of truthfulness.

(iv.) *Fidelity*.—This has respect to promises and contracts. A *promise* is a declaration that we will do something to or for another. It may be made either conditionally or unconditionally. In an unconditional promise we bind ourselves by what we give the recipient of the promise to understand is our intention in reference to the thing promised. We are not bound by whatever our words may be *made* to mean, or by whatever the promisee may *imagine* them to mean; we are bound in *foro conscientiae* by what our words, fairly interpreted, express as to our intention at the time of making the promise, or what we meant them to convey to the mind of the promisee. A conditional promise is one, the fulfilment of which both parties agree to suspend on the happening of something doubtful. Thus, if A promises to give a sum of money to B, provided something B has told him shall turn out to be true, the promise is conditional, and no breach of promise ensues if, on its being found that what B said was not true, A should refuse to pay the stipulated sum. It may be added, that there is a sense in which all promises are conditional, inasmuch as all are suspended on the presumption that it is *possible* and *lawful* to do the thing promised; but in ordinary language, it is only when the possibility or lawfulness of the act is doubtful, that this is understood to impose a condition on the promise.

A *contract* is a species of conditional promise in which one party binds himself to another in consideration of something which that party has done or binds himself to do in return. Such a contract to be valid must be made voluntarily and intelligently; if either force has been used to compel to the contract, or one of the contracting parties is not of sound mind, or incapable of forming a just estimate of the obligation he is incurring, the contract is void. Abstracting from such cases, all contracts are to be faithfully kept according to the understanding which it was the intention of the contracting parties to convey to each other. If, however, the party who accepts the contract fail to fulfil his part of the engagement, the other party is *ipso facto* absolved from the obligation resting on him, and may even be entitled to compensation at the hands of the other for loss or injury he may have sustained. Under the head of contracts are included buying and selling, borrowing and lending, hiring and service, partnership in business, and such like.

Obs. The Roman jurists, who have studied all questions affecting what may be called commercial Ethics with the utmost minuteness, have been specially successful in describing the nature and law of contract. The following extract presents in a condensed form their teaching on this subject:—"Contractus est conventio sive consensus plurium in unum placitum, habens causam, i.e., civile aliquid negotium dandi aut faciendi. Contractus vero nomine venit non tantum ea obligatio quæ synallagma habet, i.e., quæ ultro citroque obligat, cujusmodi est *emptio, venditio, locatio, conductio*; verum et ea quæ ex altera tantum parte, veluti *mutuum, stipulatio*; sive etiam in suo stet nomine sive transeat in proprium nomen contractus. Quibus verbis insinuat nova contractuum divisio in Nominatos et Innominatos. Nominati dicuntur quibus certum et proprium a legibus nomen est attributum ut *emptio, locatio, societas* ex quibus certa nominataque actio datur veluti actio *empti*, &c. Innominati vero qui certum et legitimum nomen non habent quique non ita juris vinculo continentur, cum in iis locus sit penitentiae, re integra, seu quamdiu alteruter tradendo non implevit a sua parte; suntque contractuum ejusmodi quatuor genera *Do ut Des; Do ut Facias; Facio ut Facias; Facio ut Des*; ex quibus certa et proprii nominis actio non datur sed actio præscriptis verbis, ita dicta quod ex præscripto conventionis datur." (Perezzius, *Institutiones Imperiales erotematibus distinctæ*, b. iii., tit. 14, p. 325, 8th edit. Comp. the more copious comment of Vitriarius, *Universum Jus Civile*, p. 439, ff.)

(v.) *Justice*.—Justice, as an attribute of a voluntary agent,

is the habit of mind which disposes such an one to leave all other men in the undisturbed enjoyment of whatever possessions, advantages, and privileges they may rightfully have. Self-love naturally prompts us to seek for ourselves whatever we see to be desirable; but justice teaches us sacredly to refrain from depriving our neighbour of aught that belongs to him (unless it be something which he has the power to give, and which we take with his free consent), however much the possession of it might benefit or delight us. It teaches us also not to take from our neighbour (or, what is in principle the same thing, to injure or diminish in value) anything that he prizes, even though we do not or cannot transfer it to ourselves. More specifically, justice requires us—

(1.) To abstain from injuring another man's *person*. This may be done in various ways. It may be done by inflicting wounds or blows upon him to the dismemberment of his limbs or to the interruption of the healthy action of his organs. It may be done by withholding from him necessary food, or by giving him unwholesome food, or by exposing him unnecessarily to pestilential vapours, or by preventing him from needful exercise, or by exacting from him undue and exhausting labour. It may be done also by exerting painful or depressing influences over his spirits, by which his general health is affected. When such treatment is not the result of pure accident, or of causes not subject to our will, but is to be traced to evil intention against another, or to careless indifference about another's welfare, it is to be condemned as a breach of what justice to our fellow-men demands.

(2.) To abstain from taking away the *life* of another. When this is done with deliberate and malicious intention, from revenge or for some sinister end, it is *murder*, by whatever means perpetrated, whether by blows, or by poison, or by some subtle agency the operation of which cannot be made obvious to the senses, and whether directly by our own agency or indirectly by that of others. A mitigated form of this offence is when life is sacrificed through our carelessness or thoughtlessness, without evil design on our part. This the law discriminates as *culpable homicide*. Where pure accident has caused the death of others, the instruments of this calamity are to be exempted from blame. In cases also where life has been taken in self-defence, the party must be held guiltless; for where an assailant has forced on us the alternative of either taking his life or allowing him to take ours, a duty higher than any we owe to him requires us to adopt the former of these courses. This plea, however, will not cover the practice of *duelling*; for we have no right *voluntarily* to place ourselves in such an alternative; and if it be said that the usage of society forces this alternative upon us as the only course by which, when we have been insulted, we can retain our place in society, the question then comes to be, whether the retaining of our place in society be of equal obligation with the duty of refraining from imperilling our own life or that of another—a question which the moralist can answer in but one way, in the negative.¹ It may be added, that the law which holds of the taking away of life holds equally of the preventing of life. If that be done by violent means, a crime of a very flagrant nature is perpetrated. Hence the Roman law enacted, "Si mulierem visceribus suis vim intulisse, quo partum abigerit, constiterit; eam in exilium præses provinciæ exiget."

(3.) To abstain from injuring another's *property*. A man's property is that which, by his own labour or by gift from others, has so become his, own that an abstract right belongs to him to do with it as he chooses. Hence, if he chooses to give it to others, they violate no duty in accepting it, according to the maxim of the civil law, "Volenti

¹ See a full and able discussion of duelling in Wardlaw's *Systematic Theology*, iii. 517.

Duties.

non fit injuria." But so long as he chooses to retain it, others have no right to appropriate it, in whole or in part. To do so is to be guilty of robbery, which may either be perpetrated by violence, as in highway robbery and house-breaking, or by cunning and artifice, as in pocket-picking, pilfering, and swindling. Justice to our neighbour also requires that we shall not take advantage of his ignorance to over-reach him in business or defraud him of gains which ought to be his; and also that in all transactions where we profess to transfer a portion of his property to ourselves, on the ground of giving him an equivalent for it, there shall be no deception practised with a view to make him regard as an equivalent what is not such, no fraudulent abstraction of any part of the offered equivalent after it has been accepted, and no substitution of something else in the place the very thing agreed on.

(4.) To abstain from injuring the *reputation* of others. This may be done either by saying of them what is false, or by saying of them what is true. In the former case the offence is forbidden alike by the law of veracity and the law of justice; in the latter case the law of justice prescribes that we are not to propagate what would injure our neighbour's reputation, unless some higher obligation than what we owe to him in this respect compel us to do so. Thus, if we have reason to suspect or believe that a person is dishonest, it may become our duty to give information of this, that others may be protected from his attempts; or if we know a party to have committed an offence, and are called to bear witness against him in a court of law, it will be our duty to do so; but all gratuitous and malicious tale-bearing, vituperation, or slander, whether openly uttered or conveyed by means of hint and inuendo, are direct violations of what justice to others demands.

(5.) To abstain from injuring the *virtue* of others. We may injure their virtue by misleading their judgment as to what is right and what is wrong; by tempting them to think lightly of what is immoral; by recommending vice to them through means of seductive stories or attractive representations; by appealing to their passions, or placing them in circumstances where these are appealed to; by provoking them to evil by our own example, or by using force or ridicule to constrain them to do what is wrong. Such conduct is highly criminal. It robs our neighbour of his most precious possession, a good conscience; it destroys his self-respect and mental tranquillity; it may lead to courses which end in ruin and suicide;¹ and it endangers the safety of his immortal soul. Surely, if those who maim the body or destroy life are held guilty, much deeper is the guilt of those who do their endeavour to pollute, degrade, and utterly and for ever ruin the soul.

2. *Duties owing specially to Particular Classes and Individuals.*—These may be enumerated thus:—

(i.) *Duties arising out of the Difference of Sex.*—The great duty binding on the sexes in their relation to each other is that of chastity. The law of chastity forbids not only all promiscuous and licentious intercourse between persons of different sex, but also all carnal connection between parties nearly related by blood to each other, whether under the tie of marriage or not; all polygamy, concubinage, and marriage dissolvable at the pleasure of either or both parties. It forbids also all practices tending to licentiousness; the indulgence of impure thoughts or feelings; the publication or use of obscene songs, descriptions, jests, or pictures; indecent conversations, looks, or gestures; and, in

short, whatever tends to inflame the sexual passion and loosen the restraint which should be imposed upon it.²

(ii.) *Duties arising out of the Domestic Relation.*

(1.) *Of Husband and Wife.*—Marriage is the perpetual union of one man with one woman for their mutual solacement and benefit, and with a special view to the procreation and education of children. This union is to be based on the mutual affection and free choice of the parties; all marriages formed without mutual affection, for purposes of mere convenience, for the sake of gain, or through the adhibition of force or fraud, are immoral in their nature, and seldom, if ever, are productive of happiness to the parties.

This primary law of marriage is violated where polygamy is tolerated. By such a practice all the advantages which marriage is designed to promote are precluded; woman is degraded from the companion and helpmate of man into a mere slave of his lusts;³ the happiness arising from the consociation of hearts, united by affection, is prevented; all the benefits of sympathy and united counsel are superseded; constant jealousies and quarrels invade the domestic circle; and the children, deprived of proper care and discipline, often perish in infancy, or grow up with untamed passions, jealous and hateful of each other, and without any just sense of the duties or responsibilities of life.

The law of marriage is also violated when the union of the parties is treated as dissoluble, or when it is actually dissolved, without sufficient cause. By "sufficient cause" is meant such conduct on either side as virtually destroys the consociation implied in marriage. Such is adultery, and such also, as it appears to us, is cruelty used by the one party towards the other to such an extent as renders cohabitation impossible. In such cases the marriage is really at an end, and consequently the formal separation of the parties may legitimately follow. But to dissolve a marriage for any inferior reason is immoral and mischievous.

Of the parties united in marriage the *common* duties are—(1.) The cultivation of mutual affection; (2.) Fidelity to their conjugal engagements, not in deed only but in thought and word; (3.) Care for each other's health, honour, and comfort; (4.) Mutual helpfulness, both as respects duties and sorrows, both as respects this life and that which is to come; and (5.) Mutual confidence, leading to an entire community of knowledge and interest. The *special* duties of the parties arise out of the modifications which that love which is the basis of their union receives from their respective constitutional and social differences. The husband is to give scope to his love for his wife by protecting her; providing for her maintenance and comfort; acting as her head and guide with all wisdom, patience, and gentleness; giving her honour, not only before others, but when alone, and that not in word only, but in deed; and nourishing and cherishing her as his own flesh. On the part of the wife, love is to show itself not only in the caresses of a womanly tenderness, but still more in consulting for her husband's comfort at home and for his reputation abroad; in revering him and submitting to him as her head; in taking care of his property; and in saving him from all household cares that do not properly fall to his lot.

(2.) *Of Parent and Child.*—The duties which parents owe to their children are those of nurture and education; including under the former all that is required for the physical welfare, and under the latter all that is required for the intellectual, moral, and religious up-bringing of their offspring. In their intercourse with their children, also, it

Duties

¹ Aristophanes makes Æschylus charge on Euripides the guilt of having brought many ladies, the wives of honourable men, to drink hemlock, in consequence of being brought to shame through the effect of his immoral representations. (See *The Frogs*, l. 1016.) This is but one of many instances in which the drama has had to answer for domestic misery and disgrace, ruin and suicide.

² "Nos autem," says Cicero, "naturam sequamur, et ab omni quod abhorret ab oculorum auriumque approbatione fugiamus. Status, necesse, sessio, accubitus, vultus, oculi, manuum motus, teneant illud decorum." (*De Off.*, i. 35.)

³ Animus multitudine distrahitur, nullam pro socia obtinet, omnes vires sunt. (Sallust., *De Bello Jugur.*, c. 80.)

Duties. is requisite that the law of kindness should ever be on their lips, and that their own example should be such as to command and enforce the precepts they inculcate. In the matter of discipline, the extremes to be avoided are undue laxity and indulgence on the one hand, and undue severity on the other. "A child left to himself bringeth his mother to shame;"¹ but when fathers correct in a passionate or tyrannical spirit, they are apt to increase the very evil they desire to allay; they "provoke their children to wrath," and discourage them from the path of obedience and love.

The duties of children to their parents are those of gratitude, reverence, and obedience. They are to honour their father and mother, to listen to their instructions, to avoid wounding their feelings, to be careful of their reputation, and to obey promptly and cheerfully all their commands. It is their duty also to solace the declining years of their parents by every means in their power, and, if necessary, to repay the care which nourished them in early life by supporting their parents in as much comfort as their means will allow.

(3.) *Of Brothers and Sisters.*—The duties of the fraternal relation are chiefly those of mutual goodwill; and they differ from those of the same kind which we owe to men in general only in the priority of their claim and the intensity of the affection. Goodwill to the race must be learnt in the nursery and around the domestic hearth by the exercise of goodwill and kindness between the children of the family. And all through life this, which was the first lesson to be learnt, ought to remain the strongest in its influence upon us. Other things being equal, a brother or a sister has a prior and a stronger claim on our sympathy, our kindness, and our aid, to any one standing without the family circle. "Quis amior quam frater fratri? aut quem alienum fidum invenies si tuis hostis fueris?"²

(4.) *Of Master and Servant.*—The relation of master and servant arises, except where slavery prevails, out of a contract formally or virtually made between the parties, and the duties devolving on each must be, to a considerable extent, determined by the terms of their contract. Besides these, however, there are duties of a purely moral kind which no contract can determine, and which no human legislation can enforce. It is the duty of servants not only to do what they have contracted to do, but to do it cheerfully, and with scrupulous integrity, so as to give their masters the full benefit of their time and powers. It is their duty also to show all respect to their masters, to be courteous in their manners and speech towards them, and to be always ready to vindicate their reputation as well as to protect their property. The master, on the other hand, must take care not to be unreasonable in his demands on his servants' energies, nor to treat them otherwise than with that kindness and respect which is due to his fellow-men, avoiding all overbearing deportment, all harsh and hurtful speeches, all contemptuous treatment, and all passionate threatening, in his intercourse with them. The master who not only gives his servants "that which is just and equal," but treats them respectfully and kindly, will find his own interest greatly promoted thereby; whereas "he that troubleth his own house shall inherit the wind."³

(iii.) *Duties arising out of Difference of Condition and Circumstances.*—Of these the most important are those created by differences of rank and of property. In most states some persons are raised to an artificial dignity, which is symbolized by a title or by some personal decoration; in all states where order prevails some are invested with official rank; and everywhere the distinctions of rich and poor, prosperous and suffering, obtains. Out of these arise certain moral obligations, resting on one or both parties. The duty of the great and wealthy is to show kindness to

their inferiors in society, and especially to employ their influence and resources to alleviate the sufferings of the unhappy, and to provide for the support of the destitute. Institutions for the cure of disease, for the education of the ignorant, for the reclaiming of the profligate, and for the comfort of the aged and the indigent, are entitled to look for support to those whom Providence has blessed with plenty; and the duty of charity to the poor is one of constant obligation on all who have anything to spare. On the other hand, those who are in possession of rank and dignity are entitled to expect from their inferiors in society that respect and homage which belong to their station; honour is to be given to whom honour is due. The poor also owe to their benefactors the duty of gratitude for benefits received, and the duty also of scrupulously abstaining from unnecessarily taxing their generosity, or laying a burden on their resources.

(iv.) *Duties of Teacher and Taught.*—The duty of the teacher is to use every endeavour to make himself thoroughly master of the subject which he has to teach, to divest himself of all prejudices and interests that would preclude his seeking after and embracing truth, to aim at clearness and precision in all his communications with his learners, and to use the influence he possesses under a constant sense of responsibility, and with a sacred regard to the cause of morality and religion. This applies not only to the professed teacher, but to all who by tongue or pen seek to influence the opinions or conduct of others. To his teacher the learner owes respect, docility, deference, and gratitude, but not abject submission to his dogmas, nor an acceptance of his *ipse dixit* in lieu of all reason or argument.

3. *Duties connected with the Relations of Civil Society.*—Civil society is the ordinance of God,—not that He has in any code enacted that men shall live in such society, or anywhere prescribed any particular form of civil polity as alone accordant with His will; but that He has so constituted man that to live in society is not only natural to man, but necessary for the full development of his capacities and for his well-being. "Man by nature," says Aristotle, "is a political animal (*φύσει πολιτικὸν ζῷον*), and if any one lives out of society by choice and not by misfortune, he is either a bad man or better than man;" and again he says, "If any man is incapable of associating, or through self-sufficiency needs it not, he is no part of a state,—such an one is either a beast or a god." "By nature," he adds, "there is a propensity in all to such association; and he who first instituted it became the author of the greatest benefits."⁴ It should consequently be esteemed a privilege to be a member of a state; for even in the worst ordered states the condition of the people is better than it would have been had there been no civil society at all; and in proportion as the constitution under which we live is wisely and righteously ordered, in that proportion does it demand the reverence, the support, and the love of the citizens. The body of the citizens, indeed, constitutes the state, and it is for their benefit, and theoretically by their will, that it exists; but the state, as an organic whole, may be thought apart from the individuals that compose it, and thus two parties may be represented to the mind as owing civil duties to each other,—the *πολις* or state, and its citizens (*πολίται*). Practically this distinction resolves itself almost wholly into that of rulers and ruled.

(i.) *Duties of States to each other.*—These are analogous to those of individuals to each other. States, in their dealings with each other, are bound not merely by artificial compacts and accidental treaties, but by the dictates of that great moral law which, as Cicero sublimely says, "is not one at Rome and another at Athens,—one now and

Duties.

another afterwards; but it is one and the same eternal and immortal law which holds together all nations through all times; and one God, the common master, as it were, and commander of all, who is the discoverer, the umpire, the enactor of this law; and the man who obeys Him not is untrue to himself, and contemns the nature of man, and on this very account shall endure severest punishment, even although he may escape other penalties, as they are considered."¹ Hence nations are morally precluded from making aggressions on each other's territory, or doing aught gratuitously, avariciously, or vindictively, to damage the prosperity of each other. Instead of this, there ought to be a firm alliance among the nations, binding them to respect each other's rights, to refrain from in any way seeking each other's injury, and to refer all disputes that may arise between any to the arbitration of some common tribunal. In the present state of the world, however, especially where states in very different stages of civilization are placed in close contact with each other, such a state of things can at the best be only approximately reached, and in many cases not at all. Hence aggressions will be made by the stronger on the weaker, by the more restless and needy on the more civilized, industrious, and wealthy; and constantly cases will be arising of misunderstanding and conflict between even those states which are most devoted to the arts of peace. In such cases the resort will in all probability be to arms, as the only arbitrement to which the dispute can be referred; and however horrible in many of its aspects such an expedient may be, there does not appear to be any ground on which the moralist can condemn it, apart from circumstances. Nations as well as individuals possess the right of self-defence; and if either their liberties or their possessions are forcibly invaded, they not only are morally at liberty to resist force by force for the protection of these, but they are bound, by a duty higher than any they owe to the invading power, to do their utmost to repel its assault. It is only an extension of the same principle when nations are justified in going to war for the purpose of restraining the ambition or repressing the advances of some warlike power; which, though it may not have directly attacked them, is pursuing a course such as cannot but bring it into collision with them, and that under circumstances less favourable to them than if the collision took place now; for if it be right to repel an attack when made, it is on the same ground-right to prevent, if possible, the attack from being made when it might be impossible to repel it. It is less clear whether nations are justified in going to war for causes which do not touch upon either their liberties or their possessions,—such as questions of commercial prerogative, national honour, theoretical policy, or dynastic alliance. On a calm survey of such cases, the balance seems to decline in favour of the negative side of the question, and it can only be in very urgent cases that so frightful an expedient as war can be justified for any such cause.

(ii.) *Duties of States to their Subjects.*—The prime duty of a state to its subjects is that of affording protection to their lives, liberties, persons, and properties; for which ends laws must be enacted, courts of justice instituted, and an efficient executive force maintained. In the enacting of laws, sacred regard is to be had to the interests of the community as a whole, as the end for which the law is made; and in the judicial administration of them impartiality is scrupulously to be maintained, without any respect of persons, either through fear or favour. The supreme duty of the executive consists in fidelity to the trust reposed in them, to be shown by vigilance in the detection of offenders, and unflinching performance of what the law enacts, and the

judge has determined, as due to the offence; but with this should be united the utmost possible avoidance of all personal feeling against the culprit, and the exhibition of as much of gentleness and forbearance as may be compatible with the faithful discharge of official duty. But though protection be the principal duty of a state towards its subjects, it may legitimately extend its operations beyond that, and make provision for the advancement of the commercial prosperity of the community, for the prevention of influences prejudicial to public health or morals, for the education of the people, for the relief of the poor, and for the cure of disease.

(iii.) *Duties of Subjects to the State.*—These are,—(1.) Subjection to the constituted authorities—"the powers that be." It is not implied in this that subjects are bound to approve of every law or act of their rulers, nor that they may not use means to obtain the repeal of oppressive or unwise laws; but simply that, in their capacity as citizens, they are not to set themselves against their rulers, nor to refuse obedience to the laws which are in operation. To this obedience there is but one limit, and that is, when the law requires what it would be plainly a sin against God to perform. In this case a higher law demands that the law of the human legislator should be disobeyed; only this must be done as quietly and as respectfully to the authorities as possible. (2.) The rendering of homage and respect to the magistrate as such, to be shown in the avoidance of all impertinent familiarity, all uncourteous language or deportment, and all severe and railing censure. (3.) The prompt as well as honest payment of all the taxes appointed to be levied by the proper authorities, regarding this as a debt due to government for the benefits it secures to society, and esteeming it a privilege that the amount we have to pay for this is *fixed*, so that it neither depends on the caprice of individuals, nor is left to the dubious and perplexing settlement of our own conscience. (4.) The being ready to make sacrifice of personal ease, property, and, if need be, safety, for the defence of our country, and the being forward to promote, as we have the means, the intellectual, moral, social, and political improvement of the community.

Duties.

SECT. III.—DUTIES WHICH MAN OWES TO GOD.

Some German philosophers and theologians have advanced the opinion, that it is incompetent for philosophy to attempt to determine the duties we owe to God; and some have even gone so far as to assert that man owes no duties to God distinct from those which he owes to himself and his fellow-creatures. With those who hold pantheistic views, such conclusions are unavoidable; for if God be not personally distinct from the universe, it becomes absurd to speak of our owing anything to Him as a being with whom we have special relations. But the opinion is not confined to the pantheistic school; it is advanced also by some who strenuously uphold the belief in an extra-mundane Deity. Of these we may take Kant as *instar omnium*; and it may suffice here to notice what he has said on the subject.² After asserting that, "in respect of an essence which lies entirely beyond the sphere of our experience, and yet is, as respects its possibility, found in our ideas,—namely, the Deity,—we have indeed a duty, which is called duty of religion, and this consists in the recognition of all our duties as divine commands," he goes on to say,—“But this is not the consciousness of a duty *towards* God; for since this idea proceeds entirely from our own reason, and is made by us with a theoretical view only to illustrate the conformity to purpose of the universe, or to serve as a motive

¹ Fragment of the 3d book of the treatise *De Republica*, preserved by Lactantius, Inst. vi. 8.

² See also Garve's *Philosophische Abhandlungen*, appended to his translation of Cicero, *De Officiis*, vol. ii., p. 55, ff., 6th ed.; Tieftrunk, *Grundriss d. Sittenlehre*, vol. i., p. 272, ff.; Niemeyer, *Handbuch für Christliche Religionslehrer*, p. 66, ff.

Duties.

affecting our behaviour, it follows that we have here before us no given being *towards* which our obligation binds us. In order to this, his actuality must be first proved by experience (or revelation); but it is a duty of man to himself to apply this idea, which inevitably presents itself to the reason, to the moral law in us, where it is of the greatest moral fruitfulness.¹ Now, without adverting here to other questionable doctrines taught in these sentences, let us confine ourselves to the argument they contain against the possibility of our realizing duties towards God. This, it will be seen, rests solely on the assumption that we can be under moral obligation only towards beings whose actual existence we know by experience. But is this assumption tenable? Is experience the only medium through which we may arrive at a conviction of the actual existence of any being? And provided we know a being actually to exist, and to exist in relation to us, is it of the least moment *how* we acquire that knowledge, in respect of the duties which our ascertained relation to this being imposes on us? In the case before us, if we have sufficient assurance that God exists, and that He is a being with whom we have to do, we surely know enough to enable us to go some length at least in determining the duties we owe to Him. But it may be said, as Kant has, in the passage quoted, distinctly affirmed, that our knowledge of God does not amount to such assurance of His existence and of our relation to Him, but exists merely in the form of an idea or unavoidable conclusion of reason. Now, if the whole amount of what reason constrains us to conclude on this subject were, that something is conceived by us as theoretically possible, and is assumed by us to exist in order to complete our theory of the universe, it must be granted that towards such a being we could have no duties to perform. But we may appeal with confidence to the consciousness of the race, whether this be the only idea of God instilled into us by natural reason. At the very least, the something which is conceived of as accounting for the evidences of design and purpose in the arrangement of the universe is conceived of as a *causal* something, as a being who has brought into actual manifestation what previously existed potentially in himself, and must have been contemplated as the object of purpose in his mind. Kant himself admits this in another part of his writings. "The existing world," says he, "presents to us so immense a scene of variety, order, adaptation, and beauty, . . . that the universal All must sink into the abyss of nonentity, unless we assume something that, outside of this boundless realm of the contingent, and existing primarily and independently for itself, upholds it, and, as the cause of its origin, secures to it also its continuance."² But if men know this much, they know enough to enable them to perceive a relation between themselves and this being, and enough consequently to enable them to determine that they owe *some* duties to Him. It is granted that the knowledge thus acquired is limited and imperfect, but it is sufficient to lay the basis of duty on the part of man towards God.

There is a sense in which all our duties are duties to God, inasmuch as all are comprehended in obedience to His will. But there are some duties of which He is directly the object, and it is to these we have now to attend.

(i.) It is our duty to seek earnestly to have just views of the being and perfections of God. Such views lie at the basis of all true piety: we are pious just in proportion as we think worthily of God; all religious emotion which does not spring out of just conceptions of God is mere superstition,

and is only offensive to Him. "Primus est Deorum cultus Deos credere," says a heathen philosopher, "deinde reddere illis majestatem suam."³ Hence the duty binding on all to follow up the convictions which nature may have impressed on them respecting the existence of God, by inquiring diligently whether He have given any more precise and complete revelation of Himself, and the duty of candidly examining the evidence of that book which professes to contain such a revelation.⁴

(ii.) It is our duty to cherish proper affections towards God. It behoves us to regard Him with reverence and holy fear, and to speak of Him with awe; to exercise constant dependence on Him, trust in Him, and submission to Him; to cultivate entire and cheerful resignation to His will; to delight in Him as the All-Perfect and All-Holy; and to gratefully love Him as our bountiful Father, from whose favour a continual stream of benefits descends upon us.

(iii.) It is our duty to exemplify our devout feelings towards God by appropriate acts. We are bound to receive with implicit belief whatever He makes known to us, assured that He neither can deceive nor be deceived; and on the same ground we are bound to have faith in that constitution and order which He has established in nature, including those natural sources of knowledge which He has opened in our own souls. We are bound to offer Him formal worship as an expression of internal love and reverence,—celebrating His praises, commemorating His goodness, and "speaking of the glorious honour of His majesty." We are bound to pray to Him for what we need, with confession of our sins and acknowledgment of His constant care and kindness. We are bound to swear only by His name; but we are not to take that name upon any trivial matter, on any matter of less than urgent importance; and having sworn by Him, we must dread, as a sin of enormous magnitude, the violating in the minutest particular of our oath. We are bound to practice the most steadfast obedience to all His commandments, and to use all our energies, and capacities, and opportunities, so as to serve Him and manifest His glory.

(iv.) It is our duty to imitate God's character and methods of acting, so far as may be competent to us. Infinitely as we are beneath Him in knowledge and power and goodness, we yet find in Him not only the source of all moral excellence, but the perfect model to which we, as moral agents, have to conform. All our studies, therefore, of his character and ways should be directed towards an assimilation of our characters to His, and our conduct to His. So important a place does the imitating of God occupy in the moral and religious life of man, that it is presented in Scripture as the counterpart and complement of our filial relation to God: "Be ye imitators of God, as dear children."⁵

SECT. IV.—COLLISION OF DUTIES.

Strictly speaking, there can be no collision of duties: in themselves, and viewed in the pure light of reason, all duties are in perfect harmony with each other. Nor can there be any real collision of duties practically; for when two duties appear opposed to each other, either the reasons in morality urging to the one exactly balance the reasons urging to the other, in which case the agent is placed in a moral lock, where one of the conditions of virtue, liberty of choice, is denied to him, so that neither of the two is a duty for him in the circumstances; or the reasons for the one overbalance the reasons for the other, in which case the latter ceases in the circumstances to be his duty. Cases, however, frequently

¹ *Tugendlehre*, Works, ix., 300. See also *Rechtslehre*, p. 46 of the same volume.

² *Kritik d. Reinen Vernunft*, p. 650.

³ Seneca, *Ep.* xcv. Comp. Epictetus, *Ench.*, ch. xxxi.: τῆς πρὸς τοὺς θεοὺς εὐσεβείας, ἡδὴ ὅτι τὸ κυριώτατον ἐκείνῳ ἐστὶν ὁρᾶς ὑπολαβεῖν περὶ αὐτῶν ἔχειν, &c.

⁴ Eph. v. 1. Not far from the same thought is the sentiment of the heathen Seneca,—*"Satis illos (Deos) coluit quisquis imitatus est."* (*Ep.* 95.)

⁵ See Chalmers, *Natural Theology*, ch. ii., Works, vol. i., p. 56.

Duties.

Happiness. occur in actual life, where of two duties only one can be performed by us, and it is in reference to such cases that the phrase "collision of duties" is used.

In all such cases the question which each man has to determine is, on which side the overbalance of obligation lies; and this can be determined only by ascertaining which of the duties is urged upon us by the greater force of moral reasons. In pursuing this inquiry care must be taken to abstract from all considerations of expediency or advantage; for these do not enter into a moral calculation, and if allowed to sway the judgment may lead to an immoral conclusion.

To lay down rules for the guidance of conscience in such cases belongs to the science of Casuistry, or, as Kant calls it, "The Dialectic of Conscience." We can only here suggest one or two rules of a general kind.¹

(i.) We must distinguish duties of *universal* obligation from duties of *particular* obligation, and assign to the former a superior moral authority to that of the latter. Thus, to speak the truth is a duty of universal obligation, whilst the duties arising out of social or domestic relations are of particular obligation; hence, if the latter cannot be performed without violating the former, they cease in such a case to be binding.

OBS. A question has been raised and discussed by all casuists, whether cases of necessity do not justify the telling of a lie—the case, e.g., where, by telling the truth, we may cause serious injury, perhaps death, to a friend or relative. On this point the following remarks of Fichte are worthy of attention as going far to settle the question:—"The justification of a lie of necessity, or in general a lie for the sake of some good end, is without doubt the most senseless and the most perverse that can be heard among men. It is the most senseless. Thou sayest to me, that thou hast convinced thyself that a lie of necessity is permitted. Now, if I am to believe this, I must no less disbelieve it; for I cannot know whether thou, even whilst thou art speaking, mayest not, for the sake of some praiseworthy end—who can know all thy ends?—be making use of thy maxim against me, and whether, consequently, thine assurance that thou holdest a lie of necessity allowable, may not be itself a lie of necessity. Whoever really holds such a maxim can neither declare that he holds it, nor wish to make others hold it: he must carefully shut it up in himself, and wish it to be held only for himself; communicated, it destroys itself. . . . Without doubt, then, it is pure nonsense to demand belief for what, if it is believed, annuls itself. The justification of such a lie is further the most perverse that is possible for man: the justifier thereby discloses his thoroughly corrupt mode of thought. That the lie should have occurred to you as a possible means of escape from certain contingencies, and that you

can seriously deliberate whether one may avail himself of such, is **Happiness.** the true seat of your corruptness. In nature there is no instinct toward lies; the ethical mode of thought knows not the lie; there needs for this thought something positively evil, a reflective searching after some crooked way, and desire not to follow the straight path which offers itself to us. To the virtuous man this expedient does not occur; and were it left to him, the concept of lying would not be brought into the system of human concepts, nor the question as to the morality of a lie of necessity into ethics."²

(ii.) We must distinguish duties of *primary* from duties of *secondary* obligation, and give the former the preference in cases of apparent collision. Thus, to do justice is a duty of primary, to be generous a duty of secondary obligation; and hence we can be generous only when we have fulfilled the requirements of justice.

(iii.) As our duties arise out of our relations, their comparative urgency—i.e., the degree in which we are morally obliged to perform them—varies according to the number and closeness of these relations. Hence our duty to God, to whom we sustain the most numerous and intimate relations, far transcends any duty we may owe to creatures, and must be allowed, consequently, to take precedence of all such duties: we must obey God rather than men, and love and honour Him above all beings. On the same principle, our relations and friends and fellow-countrymen have a claim upon us which is strong in proportion to their proximity to us, and in that order must the calls of duty in relation to them be obeyed.

(iv.) We must distinguish between what is simply *right* and what is *meritorious*. As a mere matter of rectitude, for instance, no man is required to prefer the interests of others to his own; but when a man chooses to sacrifice what he owes to himself for the good of others, he not only does no wrong, but he acquires merit and deserves reward. Hence, if my duty to myself requires me to follow one course, and the duties I owe to others require me to follow another, no one can justly blame me if I follow the former, but as little can any commend me unless I follow the latter.

(v.) Sometimes *mere circumstances* may determine us in our choice of duties. Thus, if I see several persons in danger of drowning, all equally indifferent to me, and of whom I can save only one, the question, *Which* one? may be best determined by circumstances, such as proximity of position, ease or certainty of success, &c.

PART IV.—OF HAPPINESS.

1. Happiness is the repose of an intelligent being in the full enjoyment of all that, according to its nature, it seeks. The term describes a purely subjective state, which must not be confounded with the objective possession of what is desirable; for a being may have everything that he can desire, and yet not be happy. Of happiness it has been justly said,—"Its home is within us rather than without us; to be happy depends less on what is possessed, than on how one regards and uses the possession."³

OBS. Kant defines happiness thus: "Happiness is the condition of an intelligent being in the world, to whom, in the whole of his existence, everything happens according to will and wish; and it rests, consequently, on the accordance of nature with his whole aims, by implication with the essential determining motives of his will." (*Kritik. d. Prakt. Vern.*, b. ii., chap. ii., sect. 5; vol. viii., p. 264, of his collected works.)

"Actual or formal felicity," says Leighton, "is the full possession and enjoyment of that complete and chief good [that, namely, which most perfectly supplies all the wants and satisfies all the cravings of our rational appetites]. It consists in a perfect tran-

quillity of the mind; not a dull and stupified indolence, like the calm that reigns in the Dead Sea, but such a peace of mind as is lively, active, and constantly attended with the purest joy; not a mere absence of uneasiness and pain, but such a perfect ease as is constantly accompanied with the most perfect satisfaction and supreme delight; and if the term had not been degraded by the mean uses to which it has been prostituted, I should not scruple to call it pleasure." (*Theological Lectures*, p. 18, Eng. tr., Lond. 1763.)

2. To aim at the attainment of happiness is inseparable from the constitution of man, or, indeed, of any intelligent agent; for it would be absurd to suppose a being, capable of happiness and endued with intelligence, who should be indifferent whether he was happy or not. Hence, as the schoolmen were wont to say, "in beatitudinem fertur voluntas, non ut voluntas sed ut natura,"—the will is borne towards happiness, not as will, but as nature. Happiness is, indeed, as Pope calls it, "our being's end and aim,"—

"That something still which prompts the eternal sigh,
For which we bear to live, or dare to die."⁴

¹ See Ames, *De Conscientia et ejus jure vel casibus*, Amst. 1630; Perkins, *Cases of Conscience*, 4to, Lond. 1635; Sanderson, *Casus Conscientie*, Cant. 1688; Taylor, *Ductor Dubitantium*, &c., fol., Lond. 1660; Kant's *Tugendlehre*, &c. ² *System der Sittenlehre*, pp. 371-3. ³ Weissäcker in Herzog's *Real-Encyclopädie*. ⁴ *Essay on Man*, Ep. iv., l. 3, 4.

Happiness. But though universally sought, happiness is not always or generally wisely sought by men. It is too often after a "confused manner," as Barrow expresses it, that they pursue their quest; "they rove through all the forest of creatures, and beat every bush of nature for it, hoping to catch it either in natural endowments and improvements of soul, or in the gifts of fortune, or in the acquists of industry,—in temporal possessions, in sensual enjoyments, in ludicrous diversions and amusements of fancy, or in gratification of their appetites and passions. They all hunt for it, though following a different scent and running in various tracks; . . . but all search in vain, or without any considerable success; finding at most, instead of it, some faint shadows or transitory flashes of pleasure, the which, depending on causes very contingent and mutable, residing in a frail temper of fluid humours of body, consisting in slight touches on the organs of sense, in frisks of the corporeal spirits, or in fumes and vapours twitching the imagination, do soon flag and expire; their short enjoyment being also tempered with regret, being easily dashed by any cross accident, soon declining into a nauseous satiety, and in the end degenerating into gall and bitter remorse."¹ Besides being true to the life, this passage suggests some of the causes, natural, and resulting from acquired habits, by which men are misled in their pursuit of happiness, or prevented from attaining it.²

3. The simple psychological law of happiness is, that the conative energies of our nature should terminate on the object to which they are directed. Thus happiness, so far as dependent on the appetites, is secured by the gratification of these; and so in respect of all our desires and passions, happiness, in so far as dependent on them, is secured by the attainment of the object by which they are excited. It is evident, however, that this psychological law will not cover all the requirements of the case; for unless there be some power to control and regulate our conative energies, man may enlarge his desires so as to render the supply of them impossible, or he may so fix his affections on unworthy objects as to do violence to his own higher nature. To this psychological law, therefore, must be added an ethical one that shall prescribe the order in which the various objects of human affection are to be sought, and the degree in which each is to be desired.

4. This ethical law may be presented under two forms: either we may determine among things desirable that which is most worthy of human pursuit, and enjoin upon man the attainment of this as his supreme end, and of other objects in the degree of their relative importance as compared with this; or we may analyze man's own nature, and making an estimate of the relative value of each of its parts, exhort him to cultivate and satisfy them, in the order and degree of their relative value.

The former of these methods was that chiefly affected by the ancient philosophers, whose ethical speculations terminated on the determination of the *summum bonum* or chief good of man. Their success, however, was not such as to prepossess us in favour of this method of prosecuting the inquiry; for their researches plunged them in endless diversity and controversy,³ and tended ultimately rather to give a handle to the mockeries of the sceptic than to guide the sincere inquirer. Besides, if happiness depend rather on the mental condition of the individual than on the actual attainment by him of any outward good, it would seem altogether the more rational and hopeful course, in attempt-

ing to lay down rules for the attainment of happiness, to survey the subject in relation to man's own tendencies and capacities.

5. To man there may be said to belong two natures,—a higher and a lower. Of these, the latter embraces his animal functions, and the appetites and desires pertaining to these; and to the former belong his intellectual and moral capacities, with the desires and affections connected with them. In virtue of the one, man is connected with the brutes that perish, however much he may surpass them in excellence and beauty; in virtue of the other, man is assimilated to God, however far below Him in majesty and perfection; and hence there can be no doubt that the one is properly denominated the higher, *i.e.*, the more dignified, the more important, the more precious; the other the lower, that is, the less worthy and estimable. On this distinction, then, would we erect the ethical law of happiness. It may be enunciated thus:—So live as to secure primarily the full development and free activity of the higher powers, tendencies, and desires of your nature, and let the lower be attended to, ever as in subordination to these.

But in the higher nature of man there are also degrees. Embracing as it does the moral and intellectual being of man, it contemplates him as a creature made for religion, for virtue, and for intelligence. Now these do not stand on the same level either in dignity or worth. However precious be intelligence, it is not equal to virtue; and virtue, which falls short of religion, fails to provide for man's loftiest susceptibilities and most weighty interests. The order, then, in which these claim the attention of man is that in which we have named them. Religion occupies the highest place, and demands his supreme attention; virtue next; and knowledge, as subordinate to these.

6. When, then, religion and virtue predominate in man's nature, when his intellectual powers are exerted in the pursuit of knowledge as in subordination to piety and morality, and when all his animal propensities are kept under the control of reason and conscience, he obeys the great ethical law of happiness, and cannot fail to secure that measure of it which is attainable in the present life, and the fulness of it in that life which is to come.

7. If these remarks are just, it will not be difficult to answer a question which sometimes has perplexed inquirers, *viz.*, In how far the pursuit of pleasure, as pleasure, is consistent with morality? On this question it is possible for the moralist to take much too high ground, and, by denouncing too vehemently and unqualifiedly all pleasure-seeking, to place his teachings in antagonism with the natural constitution of man and the obvious will of God. For man is made to seek pleasure as an end; and it is to be inferred that God wills it to be so, inasmuch as He has bestowed upon us so many susceptibilities of pleasurable enjoyment, has opened for us so many sources of pleasure, and has impressed upon us so strong a tendency to seek pleasure for its own sake. But there are limits to this pursuit within which alone it can be legitimately indulged.

These limits are transgressed—1. When men make mere enjoyment the sole or the supreme end of life; when they make nothing a study, nothing a duty, nothing a work, but are solely or chiefly occupied in flying from amusement to amusement; when, whether they are intellectually amused or sensually amused, they find in the mere amusement their end, and never rise beyond this in either case.

2. When men pursue pleasure to the neglect of duty;

¹ Barrow, *Sermon xliii.*, Works by Hughes, vol. iii., p. 136.

² Mr Stewart has treated, with his usual sagacity and at length, the same aspect of the subject in his *Philosophy of the Active and Moral Powers*, vol. ii., p. 376, ff.

³ *Alii in animo, alii in corpore, alii in utroque fines bonorum posuerunt et malorum. Ex qua tripartita velut generalium distributione sectarum, M. Varro in libro de Philosophia tam multam dogmatum varietatem diligenter et subtiliter scrutatus advertit ut ad ducentas octaginta et octo sectas, non quæ jam essent sed quæ esse possent, adhibens quasdam differentias facillime perveniret.* (Augustine, *De Civ. Dei*, b. xix., c. i.)

Happiness. whether the duty neglected be one owing to themselves, such as temperance and moderation, or one owing to others, such as equity and honesty, or one owing to God, such as worship and obedience. 3. When men pursue pleasure so as to enervate their intellectual faculties, to blunt their moral susceptibilities, and to create a sensitiveness of the nervous system or the æsthetic faculty which unfits for the actual business of life. In all such cases pleasure is pursued immorally and to the permanent injury of the party; so that what our bountiful Creator gave us for a blessing is perversely turned into a curse; and what was intended to add to our happiness becomes a source of misery.

8. It only remains that we should advert to the question touching the relation to each other of goodness and happiness as supreme ends of human effort. As man is bound to both, they cannot be antagonistic to each other. But how are they connected with each other? Is the one to be absorbed in the other, or are they distinct and independent of each other?

By the ancient philosophers, with whom this question was one much discussed, the former of these positions was universally maintained; they differed only as to which of the two was the superior and absorbing power. On this point the Epicureans and the Stoics occupied the antipodal positions; the former of whom held that virtue was an accidental element of happiness, the latter that happiness was an accidental element in virtue. "To be consciously influenced by maxims that lead to happiness is virtue," exclaimed the Epicureans. "To be conscious of virtue is happiness," rejoined the Stoic. Kant, however, has shown¹ that such a connection of the two is untenable; that they are so different in kind, that identity cannot be sought between them. He maintains, further, that the connection between them is not causal; for experience shows us that neither is the desire for happiness a motive to virtue, nor is virtue an immediate cause of happiness, otherwise all virtuous persons would be happy in proportion to their goodness. He would, therefore, keep the two distinct as independent ends for man. There thus emerges what, in the peculiar phraseology of his school, he calls "the antinomy of the practical reason;" i.e., not a case where two assumptions contradict each other, so that if one of them be true, the other must be false; but a case in which two propositions are both known to be true, yet cannot be construed in their harmony to the mind. Man is bound to pursue virtue; man cannot but pursue happiness; and yet neither are these identical, nor does the one lead directly to the other. This antinomy can be resolved only by taking into account the whole extent of man's being as destined for immortality, and spending now a probationary life for the future; and along with this his relation

to God, in whom perfect holiness and perfect happiness **Happiness.** are eternally conjoined; and who, having all things under his control, not only can reward the obedience of his servants here by a futurity of blessedness, but can make even present sufferings and sorrows conducive to future felicity. It is by living at peace with Him, through that reconciliation which He graciously offers to us, and by constantly serving Him, that virtue and happiness are to be united. Though we cannot directly command happiness, we shall thus follow a course which shall secure for us, along with the pleasure that springs from doing what is right, the prospect of perfect felicity above, and the consolation amid present ills which such a prospect, and the assurance that these ills will themselves be made conducive to a higher measure of felicity, cannot but communicate.

9. The conclusion at which we thus arrive is that in which alone the mind can rest. If we confine our view to the present state, it becomes impossible to show whether happiness or virtue should be the supreme object of pursuit. "When disputing with my friend," says Augustine, "concerning the ends of good and bad, I would have given the palm to Epicurus in my own mind, had it not been for my belief in the soul's life and the reach of deserts after death."² The natural conclusion of the majority of men, when the moral government of God and a future state of rewards and punishments, consequent upon our conduct in the present, is denied or overlooked, is that expressed by the words, "Let us eat and drink, for to-morrow we die." On the other hand, to the cultivated few the beauty of virtue, and the advantages of it, may appear such as to induce them to prefer it to all sensual indulgence; and they may loudly and eloquently commend the same course to others. But if, after all, the decision is to turn merely on which course produces the largest amount of present enjoyment, the majority will still be on the side of pleasure; and rightly, for if there be no futurity and no final retribution, a life of careless ease and sensual enjoyment is on the whole to be preferred to one of self-denial, toil, and struggle. It is only when the mind realizes man's true condition, as the subject of a moral government which is administered on a scheme of rewards and punishments, consequent on the desert of conduct, that the supreme importance of virtue and holiness is perceived; and men are disposed to count nothing a loss by which these are secured, and nothing a gain by which they are forfeited or missed.

"Si ergo quærat a nobis quid civitas Dei de his singulis interrogata respondeat, ac primum de finibus bonorum malorumque quid sentiat, respondebit æternam vitam esse summum bonum, æternam vero mortem summum malum: propter illam proinde adipiscendam, istamque vitandam recte nobis esse vivendum."³ (W. L. A.)

Morales
||
Moratin.

MORALES, AMBROSIO, a Spanish historian and antiquary, was born at Cordova in 1513. After studying at the university of Salamanca under his uncle Fernan Perez de Oliva, he assumed the garb of the Dominicans at the age of nineteen, and became a strict and zealous ecclesiastic. At the same time his literary abilities were raising him to notice. He was afterwards appointed a professor at Alcala, and his learning as an antiquary procured for him in 1570 the office of historiographer to Philip II. It was at this period, when he was sixty-seven years of age, that he began to write his continuation of Ocampo's *Chronicle of Spain*. He had brought down the narrative as far as the union of the crowns of Castile and Leon, when he died in 1591. The best edition of Morales' *Chronicle* is that of Madrid, 6 vols. 4to, 1791. To this are generally added his *Spanish Antiquities*, 2 vols., 1792, and his miscellaneous works, 3 vols., 1793.

MORALES, Luis, surnamed *El Divino*, from his character as a painter of sacred subjects, was born at Badajos in 1509. He made himself a proficient in his art by visiting the principal cities in Spain, and studying carefully the works of the different masters. His pictures of the "Saviour" and of "Magdalene" became especially famous for their faithful representation of intense bodily suffering blended with serene meekness. Morales was dragging out his old age in severe poverty, when Philip II., passing through Badajos in 1581, sought him out, and conferred upon him a pension of 300 ducats. He died at his native city in 1586. The masterpiece of Morales is his picture of "St Veronica," in the church of the Bare-footed Trinitarians in Madrid.

MORANO, a town of Naples, in the province of Calabria Citra, picturesquely situated on a conical hill on the western slope of Monte Polino, 5 miles W.N.W. of Castro-villari. The summit of the hill is occupied by an ancient Gothic castle; and the town has some manufactures of silk and woollen stuffs. Pop. 8352.

MORAT (Germ. *Murten*), a town and lake of Switzerland, in the canton of Fribourg. The town, which is situated on the eastern shore of the lake, stands on a rocky eminence surmounted by an ancient castle. The lake is about 5 miles in length by 3 in breadth, and is 60 fathoms in depth. It discharges its waters by the River Broye into the Lake of Neuchâtel. This place is celebrated as the scene of the victory gained by the Swiss in 1476 over the troops of Charles, Duke of Burgundy, in which the latter lost 15,000 on the field of battle, besides many others drowned in the lake. The bones of the dead remained for three centuries piled up in a building called an *ossuary*; but this was destroyed, and most of the bones carried away, in 1798, by the soldiers in the Burgundian legion of the French army. The few bones that remained were buried, and an obelisk raised over them on the spot where the ossuary formerly stood.

MORATIN, LEANDRO FERNANDEZ, a celebrated Spanish dramatist, was the son of the poet Nicolas Fernandez Moratin, and was born at Madrid on the 10th March 1760. Under the tuition of his father he evinced a strong devotion to poetry and painting; but it was thought a part of parental duty to divert his thoughts from such profitless aspirations towards some lucrative calling. He was therefore apprenticed at an early age to a jeweller. His poetical studies, however, were continued; and at the age of eighteen he appeared before the world as the gainer of the second prize awarded by the Spanish Academy for a heroic poem on the conquest of Granada. The winning of another prize in 1782 for a satire against poetasters, entitled *Lección Poética*, encouraged him to abandon his trade, and to hope for some more congenial calling. At the recommendation of the famous statesman Jovellanos, he was appointed secretary to Cabarrus in 1786. Attending his master in the following year at the court of Versailles, he acquired that

Moratin.

intimacy with the French drama which formed so important an element in his dramatic education. On his return to Spain in 1789, the minister, Florida Blanca, presented him with a benefice in the archbishopric of Burgos, and Moratin had only to take the tonsure to become the occupant of a sinecure of 300 ducats annually. Thus fortified against all pecuniary anxiety, he turned with enthusiasm to the prosecution of the drama. His first comedy, *El Viejo y la Niña*, was produced on the stage in 1790. Strongly marked with that regularity of plan, liveliness of dialogue, and elegance of style which afterwards became the chief basis of Moratin's fame, it called forth great applause. His *El Café*, or *La Comedia Nueva*, acted in 1792, was equally successful, and may be said to have completed that reformation of the Spanish theatre which had been begun sixty years before. In the same year Florida Blanca was disgraced; but Moratin immediately found another patron in Godoy, who bestowed upon him a pension of 600 ducats, and even supplied him with money to gratify his desire for foreign travel. He accordingly visited in succession England, Holland, Flanders, Germany, and Italy, studying the dramatic literature of each of these countries, and extending his knowledge of men and manners. On his return he began to translate the *Hamlet* of Shakspeare, the *Médecin Malgre lui* and the *École des Maris* of Molière. His most popular comedy, *El Si de las Niñas*, appeared in 1806. It was acted to crowded houses for twenty successive nights, ran through four editions in one year, and was afterwards translated into many languages. Moratin was now in the noonday of his prosperity. He was among the wealthiest of poets; he was a frequent guest in the mansions of the great, and he could retire at pleasure to indulge his æsthetic tastes in a luxurious country retreat. In 1808, however, his good fortune began to wane. His patrons were forced to flee before the French invasion, and relinquish the throne of Spain to Joseph Bonaparte. It was in vain that Moratin bartered his patriotism for the continuation of his pensions, that he temporized with the invaders, and that he allowed himself to be appointed chief librarian to the usurper. He saw himself compelled in 1812 to abandon the sinking fortunes of the French, and to take refuge in the camp of the patriots. He was received with cold distrust, his private property was sequestered, and his revenues and pensions were withheld. Even after he had been pardoned and restored to his privileges by Ferdinand VII. in 1814, his dread of official assassins would give him no rest until he had crossed the Pyrenees, and had taken up his abode at Paris. In 1821 Bordeaux became his settled residence; and there his learned work, *Origenes del Teatro Español*, was elaborated. He returned to the French capital in 1827, and died there in June of the following year. Moratin also wrote the three dramas of *El Barón*, *La Lugareña orgullosa*, and *La Mogigata*, and several lyric poems. There are several editions both of his lyrical and of his dramatic works.

MORATIN, Nicolas Fernandez, an eminent Spanish poet, was descended from an old Biscayan family, and was born at Madrid in 1737. He became at an early age a convert to the opinions of those who were attempting to drive the romantic drama off the Spanish stage. His friendship with Montiano, a cultivator of the classical tragedy, confirmed his zeal; and his earliest efforts were devoted to the cause of theatrical reform. In 1762 he published a comedy, *La Petimétra*, written in accordance with French models, and three discourses against the old drama and the *Autos Sacramentales*. The comedy did not succeed. The discourses were so far successful, that the *Autos* were condemned by a royal edict in July 1765. His ultimate measure in behalf of the reformation of the drama was taken in 1770, when he produced on the stage his tragedy of *Hormesinda*, written in entire obedience to the canons which governed

Morava
||
Moray.

Corneille and Racine. It was received with favour. Meanwhile Moratin had been displaying his finish of diction and his harmony of versification to greater advantage in several poetical works. He had published in 1764 a collection of short pieces, under the title of *El Poëta*, and in the following year a diadactic poem on the chase, entitled *Diana*. In 1765 had appeared his greatest work, the spirited historical epic styled *Las Naves de Cortès Destruídas*. Although intimate with several of the chief courtiers, Moratin disdained to cringe for promotion by hanging on the skirts of some great man. He chose rather to live in retirement, and to drudge at the uncongenial pursuit of law for the support of his wife and son. At length his appointment to succeed Ayala in the chair of poetry in the Imperial College placed him in his proper sphere. He directed his professorial instructions to that life-long aim of his, the improvement of the taste of his fellow-countrymen. To further the same project, he gathered around him the principal literary men of the capital. A club was formed, and met regularly in the "Fónda de San Sebastián," to discuss contemporaneous literature, both native and foreign; and, above all, to devise methods for reviving the decaying spirit of the country. Moratin died in 1780. A collection of his poems, with a Life, was published at Barcelona in 1821 by his son, the dramatic poet Leandro Fernandez Moratin. He was also the author of several prose works.

MORAVA, the principal river of Servia, formed by the confluence of the East and West Morava, about 30 miles W. of Nissa. The united stream flows northwards to the Danube, into which it falls at Kullica, 6 miles N.E. of Semendria, after a course of 115 miles, and the upper branches are each about 150 miles in length.

MORAVIA. See AUSTRIA.

MORAVIANS. See BOHEMIAN BRETHREN.

MORAY or ELGINSHIRE, a maritime county of Scotland, on the Moray Firth, bounded N. by the same, W. by Nairnshire, S.W. by Inverness-shire, part of which severs it into two parts, and S.E. and E. by Banffshire. The northern portion of it, lying between Inverness-shire and the sea, is 26 miles in length by 23 miles in breadth; the southern portion, inclosed by Inverness-shire, 14 miles long by 12 miles in breadth; while both together have an area of 340,000 statute acres. In its physical aspects Morayshire presents the characteristics of the Lowlands as well as those of the Highlands of Scotland. The former constitute the maritime section of the county, and the latter the interior. A light, gravelly soil, resting on a Devonian bottom, characterizes the surface of the maritime portion of the county, extending from 4 to 6 miles from the sea-coast. Undulations spread through this district, and in the parishes of Duffus and Elgin become hills of slight elevation. Southward, in the interior, the land becomes always more and more mountainous, until, on the borders of Inverness-shire and Banffshire, it attains a very considerable elevation. The geologic system of this, the highland section, is primary, with here and there strata of mountain limestone. Gneiss is the most prevalent rock among the hills, but it frequently approaches to granite in its structure, especially on the borders of Banff and Inverness shires. The climate of the county is generally considered healthy. On the coast, where the soil is gravelly, and consequently of a dry nature, the temperature is mild; but on the uplands it is more changeable and more subject to extremes. Westerly winds prevail in Morayshire for nearly three-fourths of the year; but most of the heavy gales that visit this county are from the N. or N.W. Easterly winds, however, are prevalent in spring, to the great injury of vegetation. The annual fall of rain upon the N.E. part, near Speymouth, is stated to be little more than 25 inches, and the mean temperature of the year to range from 45° to 50°. In the hilly region, however, the winter is long and often severe, and

the harvesting is generally late in being brought to a close. Moray, however, has the other advantages of an extended sea-coast, and large rivers traversing its valleys. The former stretches for about 30 miles along the Moray Firth, from the mouth of the Spey to beyond the Findhorn. It presents to the sea several bold headlands, such as Burgh and Stotefield Heads, and has likewise considerable inlets at the mouths of the Findhorn and Spey rivers. The harbours on the coast are, however, few and insecure. The principal streams of Morayshire are the Spey, on its eastern boundary; the Findhorn, on the W.; and the Lossie, in the centre of the county. The first of these rises from Loch Spey in Inverness-shire, and has about one-half its entire course in that county, after which it enters Moray at Tomachrochri. It then bounds the parish of Abernethy on the W. for about 3 miles, and afterwards separates it from the parish of Duthil. After traversing the detached part of Inverness-shire, the Spey again enters Morayshire, and forms its boundary on Banffshire for the greater part of its course downwards. The stream at last reaches the sea, below the town of Speymouth, by means of a wide mouth studded with islands, after a course of about 110 miles. It has a very rapid and tortuous course; and, after the Tay, discharges the largest volume of water of any stream in Scotland. No part of it is navigable, but it is much used for floating down timber. From the great bends in its course, together with the rapidity of its flow, the strath or valley has been long subject to very destructive inundations. The scenery on the banks of this river is frequently of a highly picturesque character. The Findhorn, which enters Moray on the west, is next in importance to the Spey. Rising among the mountains of Badenoch, it takes its meandering course north-eastwards through Inverness, and entering Nairnshire a little above Balknockan, traverses that county in the same direction. It enters Moray at Kilmoney, when it gradually turns to the N., and after receiving the waters of the Dorbas and other smaller tributaries, falls into Loch Findhorn, an inlet of the sea. Its total course is about 50 miles, for 10 of which it flows through Moray, but its waters are not navigable. Valuable salmon-fisheries pertain to the stream. Like the Spey, it is noted for sudden and destructive inundations. The "Moray floods" of 1829 were caused by a great outbreak of the Findorn. The only other river worthy of mention is the Lossie, which, rising from a loch of the same name, traverses the centre of the county by an irregular N. by E. course, receives the Lochty on its left, and, after passing the town of Elgin, empties itself into the Moray Firth after a course of 25 miles, all within this county. The surface of Morayshire is otherwise diversified by several small lakes. In regard to its soil and agriculture this county may be divided into the maritime or lowland and the highland districts. Of the first, the soil is open and well suited for both wheat and oats. The highlands, on the other hand, are, with the exception of some parts of the valleys, exclusively devoted to pasture, especially for sheep. The breeds that are fed on the hills are mostly Cheviots and black-faced, while crosses with the Leicestershire and South Downs are generally confined to the lowlands. Most of the cattle are crosses between the native breed and those of Teeswater or Aberdeenshire. The great stimulus given to the agricultural interest in the production of stock, corn, and other commodities for the metropolitan markets, by the ready communication obtained either by sea or railway, has been the cause of many improvements in farming, as well as of a steady rise in the price of land. In 1857 there were 82,401 acres in the county under rotation of crops, against 80,413 acres in the preceding year; and the following statistics for the year 1857 give the acreages as returned:—There were in that year 28,560 acres under grass and hay, 17,213 under oats, 12,737 turnips, 9522 barley, 8749 wheat, 3190 po-

Moray.

Morbihan. tatoes, 776 rye, 481 bere, 409 tares, and 284 under bare or summer fallow. Of live stock in the same year there was an aggregate of 88,916, against 90,982 in the preceding year. In 1857 the following were the specified numbers:—56,336 sheep, 23,231 cattle, 5024 horses, and 4325 swine. The number of occupants of arable lands was in the same year 1146, or 1 to every 72 acres of arable farmage. In 1856 the valuation of the county (excepting the two burghs) amounted to L.116,851, against L.113,954 in 1855, and L.62,312 in 1811. Morayshire is not rich in mineral resources; excellent sandstone, however, and limestone are to be had in the county, which latter is shipped in considerable quantities. Peat is plentiful among the hills, and is much used for fuel. Large plantations of fir, larch, and other trees, supply the county with plenty of timber, which is generally floated down the streams in rafts. The manufactures are insignificant, and consist chiefly of beer, whisky, woollens, and ropes. The Great North of Scotland Railroad traverses the lowland part of the county, and sends off a branch line from Elgin to Lossiemouth on the coast. Regular communication with the south is also kept up by means of steam-packets. Moray unites with Nairnshire in returning a member to Parliament. It belongs to the northern circuit, and the assizes are held in Aberdeen. Ecclesiastically the county pertains to the synod of Moray; and in 1851 it contained 62 churches, with 28,293 sittings. Of the former, 24 belonged to the Established, 20 to the Free, 8 to the United Presbyterian, 4 to the Independent, and 2 each to the Episcopal, Baptist, and Roman Catholic denominations. For educational purposes there are 65 public schools and 31 private seminaries. The county shares with those of Banff and Aberdeen in the Dick Bequest, left for the purpose of increasing the salaries of teachers in these three counties. The number of poor relieved in the year ending May 14, 1856, was 1472, out of a population of 39,494 (in 1851); and the total amount collected for this purpose was, in the same year, L.8904, against L.8659 expended. The present Morayshire formerly occupied the middle district of the old county of Moray. Its earliest reliable history commences with the invasion of its territory by the Danes in 1008, when Malcolm II. of Scotland marched against them, but was defeated near Forres. They afterwards brought over their wives and children, and established a settlement here; but their possession of the country was disturbed by defeats which they sustained on three different occasions at the hands of the Scots, who ultimately forced them to leave the country. Moray was then incorporated in the kingdom of Scotland. There are many antiquities in this county, one of the principal of which is Pluscardine Abbey church, on the Lossie, near Elgin, a fine cruciform edifice, with a square tower of hewn stone. It was founded in 1230 by Alexander II., and bestowed upon the monks of Valles Caulium, a reformed order of Cistercians. Darnaway Castle, in the parish of Dyke and Moy, is likewise a building of great antiquity, and has been the seat of the Earls of Moray, of the Randolph, Douglas, and Stuart families. Besides other interesting reliques, some remains of Danish monuments and fortifications are still extant. Of the former, the most remarkable is Sweno's Stone, near Forres, a large slab covered with representations of beasts, &c., 23 feet in height by about 4 in width, and said to reach into the ground for more than 10 feet. The aggregate population of the whole county was, in 1821, 31,398; in 1831, 34,498; in 1841, 35,012; and in 1851, 38,959. Of the last, 20,768 were females, and 18,191 males. Of towns containing more than 2000 inhabitants there were only two here in 1851,—viz., Elgin, the capital (6337), and Forres (3468), both of which are parliamentary and municipal burghs.

MORBIHAN, a department in the W. of France, bounded on the N. by that of Côtes-du-Nord, E. by Ille-

VOL. XV.

Morbihan. et-Vilaine, S. by Loire-Inferieure and the Bay of Biscay, and W. by Finistère. It lies between 47. 27. and 48. 15. N. Lat., and 2. 1. and 3. 38. W. Long.; and its length from E. to W. is 72 miles, by 52 in extreme breadth. Area, 3627 square miles. The coast is very much indented, and contains one remarkable inlet called the Morbihan, from which the department takes its name. The entrance is narrow, but it spreads out to a large extent inland, and contains numerous islands. To the west of the entrance of the Morbihan is the peninsula of Quiberon, extending southwards into the sea for 10 miles, and connected with the mainland by a narrow isthmus, which is covered with water at the highest tides. The bay to the east affords excellent anchorage, and is capable of containing a large number of vessels. It is protected by a fort built on the peninsula. Several islands lie off the coast of the department, the largest of which is Belle-Isle, to the south of Quiberon. The surface of Morbihan is rugged and hilly. In the north there is a range of hills covered with barren moors and heaths; but in the lower grounds there are many fertile valleys. The soil is not deep, except near the coast. The rocks of the department belong principally to the primary formation, but in some places stratified and crystalline deposits occur. There are numerous rivers, but none of any great size: they flow generally from N. to S., and some are navigable for a short distance from their mouth. The most important are,—the Blavet, Oust, Auray, and Vilaine. Morbihan is traversed by two canals, one of which follows the course of the Blavet; the other, connecting Nantes with Brest, crosses the department from S.E. to N.W. The climate is mild, but foggy; and the principal wind is from the S.W. Agriculture is not in a very advanced state, and the cultivated land is comparatively small in extent, amounting to about 666,500 acres. The pasture land occupies 170,637 acres; woods, 88,372 acres; and the moors and heaths, 720,415 acres. The department produces corn in greater quantity than is necessary for the supply of the inhabitants, so that a considerable part is exported. Rye and buckwheat are the kinds principally grown. Maize, potatoes, hemp, flax, and apples for cider, are also among the productions of Morbihan. It is further estimated to contain 295,000 horned cattle, 255,000 sheep, 10,000 goats, 60,000 swine, and 42,000 horses. Bees are kept in large numbers, and produce a very excellent quality of honey. The department contains iron and tin mines, which are worked to a considerable extent, besides quarries of granite and other building stones, slates, clay, &c., and salt-pans at various places on the coast. The manufactures of Morbihan consist chiefly of iron, linen, cloth, leather, paper, and porcelain. Ship-building is carried on to a great extent, especially at Lorient, where many of the best men-of-war in the French navy are constructed. The fisheries, especially of sardines, in which branch alone 500 boats are engaged, give employment to a large number of the inhabitants of the coast, and yield annually more than L.60,000. The principal articles exported are horses, cattle, corn, rye bread, honey, wax, fish, salt meat, &c. Morbihan is divided into four arrondissements, as follows:—

	Cantons.	Communes.	Population (1851).
Vannes	11	74	132,171
Pontivy	7	45	105,984
Lorient	11	49	148,779
Ploermel	8	61	91,238
	37	229	478,172

In 1856, however, the department contained 234 communes and 473,932 inhabitants. The capital is Vannes; but the most populous town is Lorient, which has nearly twice as many inhabitants. The people of Morbihan, like those of the other parts of Brittany, are of Celtic origin, and speak a language similar to the Welsh and Cornish dialects of our island, which have the same origin. They

Morcelli
||
Mordaunt.

are very much behind the rest of the French in civilization, and preserve almost unchanged the dress, manners, and superstitions of their ancestors. Morbihan forms the bishopric of Vannes, and has two tribunals of commerce at Vannes and Lorient.

MORCELLI, STEFANO ANTONIO, a learned antiquary, was born at Chiari in 1737. While attending school at the neighbouring city of Brescia he attracted the notice of the Jesuits, was drawn by them within their society, and was sent to study at Rome. The chair of eloquence in that city was conferred upon him in 1771. In this situation he continued zealously to advance the cause of learning, both by his teaching and by his works on antiquarian subjects, until the suppression of his order in 1773. He was then received into the house of Cardinal Albani, where, in the magnificent library of his patron, he passed several years of literary leisure, composing his chief work, *De Stilo Inscriptionum Latinarum, Libri III.* It was published at Rome in 1780. In 1791 Morcelli was recalled to Chiari to be provost of the chapter. The rest of his life was characterized throughout by self-denying benevolence. He refused the archbishopric of Ragusa, through a desire to end his days in his native town. He founded and endowed an institution for the education of young females, restored the schools, repaired the churches and other public edifices, and presented his library to his fellow-citizens. His death took place in 1821. Some of Morcelli's other works are,—*Inscriptiones Commentariis Subjectis*, 4to, Rome, 1783; *Kalendarium Ecclesiæ Constantinopolitanæ*, 2 vols. 4to, Rome, 1788; and *Africa Christiana*, 3 vols. 4to, Brescia, 1816.

MORCONE, a town of Naples, province of Molise, is situated on a hill 15 miles S.S.W. of Campobasso. It has a fort, and is surrounded by walls. The manufacture of woollen stuffs is carried on here. Pop. 5000.

MORDAUNT, CHARLES, Earl of Peterborough and Monmouth, celebrated for his extraordinary exploits both by sea and land, was the son of John, Lord Mordaunt, Viscount Avalon, and was born about the year 1658. He was brought up at the profligate court of Charles II., where he learned early to advocate scepticism and play the libertine. Sated with court pleasures and longing for adventure, he joined Sir John Narborough's fleet in his seventeenth year, and set out for the Mediterranean waters to strike a blow at the Algerine corsairs who then preyed upon the industry of the British trader. On the night of the 14th January 1675 he witnessed the destruction of the corsair ships in the harbour of Tripoli, and fought gallantly by the side of Lieutenant Cloudsley Shovel, who had the command of that daring expedition. On his return to England in 1677 he succeeded to the titles and estates of his father, who had died during his absence; and before he had attained to man's years he married a daughter of Sir Alexander Fraser of Dotes in Kincardineshire. This marriage had not the effect of improving his character: the quiet of domestic life did not suit his temper; and his wild, restless spirit burned for adventure either by flood or field. In 1678 we find him once more engaged in some fierce scuffles with the Algerine rovers; and during the following year he saw much hard fighting at the siege of Tangier. He had no sooner returned to England than he entered Parliament, and assumed his first political position as a "peer of the realm" by offering a determined opposition to the royal proposal to remove the Parliament to Oxford. From that hour he employed all his influence to thwart the royal race, against whom he had cherished a bitter hatred from his very boyhood. He had qualities in him, moreover, which rendered him a formidable opponent. He had already a reputation as a daring soldier and a bold sailor, and was well known to be an accomplished scholar and a ready wit. His mind had ever been as active as his body. Whether he was

Mordaunt.

occupied in "naying up his hangings" on Sabbath, and shocking the chaplain with his profanity while tossing about in the Bay of Biscay, or hotly engaged in boarding an African rover in the Mediterranean, he never neglected to snatch a quiet hour for reading and culture. Despite the dark menace of Judge Jeffreys and his infamous supporters, this enthusiastic young lord became an earnest partisan of Lord Russell and Algernon Sidney. He stood by those noble men to the last, and accompanied Sidney to the scaffold. Yet these ennobling associations could not wean him from indulging in occasional bursts of mad frolic and wild eccentricity. He delivered his first speech in Parliament on the 19th November 1685, in opposition to the keeping up of a standing army. It was characterized by great power and boldness, and was full of impetuous, fiery eloquence. Among his friends it excited great hopes, and among his enemies it rendered him a marked man.

His prodigal generosity, combined with a limited income, had led him into pecuniary embarrassments, and he resolved to seek that employment abroad which was denied him at home. He had a hearty hatred of Popery and despotism; and in 1686 he quitted England for Holland, then the home of liberty and Protestantism. After vainly urging the Prince of Orange to an immediate invasion of England, he took up his abode in Holland, and remained there till the Revolution. Here he formed an intimate friendship with John Locke, who was then meditating his great *Essay* in exile. Mordaunt accompanied the Prince to England in 1688, received a lieutenant-colonelcy, and did good service during that critical period. On the 9th of April 1689 he was made first commissioner of the Treasury, and on the day following was created Earl of Monmouth. He stood by his royal patron in his signal defeat in the matter of the Test Act; but many months had not elapsed before he became jealous of his Majesty, and assumed a position of hostility which cost him his office. Monmouth formed one of the council of nine appointed by the King to aid Queen Mary in directing public affairs during the absence of her royal husband in Ireland. "The nine kings," disliked and suspected each other, and Monmouth strove sedulously to damage his fellow-councillors in the eyes of the Queen. He was accused of writing the notorious *lemon letters*, and intrigued hard for the sole command of the fleet. The restless ambition and immoderate vanity of the man here, as elsewhere, proved his greatest snares. He was obviously getting tired not only of the existing government, but of the royal family itself. The campaign of 1691 gave scope to his activity; and after serving with distinction on the Continent at the head of his regiment, the Royal Horse Guards, he returned to England and went into retirement. Here he sought the society of men of letters, cultivated his mind and his garden, made a boast of his immoralities, and sneered at religion. His Majesty did not seem disposed to recall him to power, and the Earl's growing dislike to royalty continued. In 1696 he got involved in Fenwick's plot, which deprived him of all his employments, and sent him to the Tower. Here "he was as violent as a falcon just caged;" but William, with his accustomed leniency, gave early orders for his release. In the midst of his disgrace he found that he had inherited the earldom of his house; and with an undaunted front and characteristic energy, he resolved to atone for the tarnished scutcheon of Monmouth by adding fresh lustre to that of Peterborough. The way was not yet clear before him, however, and he found time to visit the pious Fenelon. On coming away, the sceptic remarked, "If I stay here another week, I shall be a Christian in spite of myself." The King died in 1702; and Marlborough had no sooner come into power under Queen Anne, than Peterborough, with his graceful flattery and brilliant wit, was by the side of Lady Marlborough, and had already conquered her dislike, and won

Mordaunt. her esteem. The war of the Spanish succession had now to be engaged in, and the Low Countries and Spain were the chosen battlefields for the arms of England. Marlborough reaped fame and fortune on the one, Peterborough amazed all Europe on the other.

Early in 1705 an English fleet and army were equipped for the Mediterranean shores of Spain, and Peterborough was named commander of the troops, and joint commander of the fleet with his old fellow-soldier, Sir Cloudsley Shovel, who long years ago had fought by his side in that fiery midnight exploit among the corsairs of Tripoli. The generous Earl well nigh beggared himself in fitting out his raw and undisciplined army of 5000 men. After much fruitless manœuvring on the Spanish coasts, he at last besieged Barcelona, and by a series of dexterous movements, characterized by unparalleled boldness, and transcendent military skill, he succeeded in making the city his own. Having left King Charles III. to the protection of his Catalan subjects, Peterborough turned his attention to the reduction of Valencia and Catalonia. This, with the means at his disposal, would have appeared to any other man an absolutely hopeless undertaking. Before him lay an enemy many thousands strong and well disciplined, commanded by able officers and secured by strong positions; while he, instead of an army, had only a small escort, imperfectly equipped, and in a hostile country beset with incredible difficulties. Against such fearful odds this audacious general, with his gallant little band, undertook to reduce the Spanish Peninsula, and commenced one of the most extraordinary campaigns to be found in the annals of warfare. What he could not effect by material strength and valour, he resolved to accomplish by superior sagacity, and, if need were, by the most unblushing deceit. He magnified his numbers by every fanciful artifice, circulated the most mendacious intelligence respecting his strength and movements, scoured the sierras with the most incredible swiftness, and swept down upon the affrighted foe with the speed and nimbleness of a falcon. He frightened his enemies by the incomprehensible mystery which the rapidity of his movements cast over all he did. All their calculations were at fault: ordinary military skill was of no avail against this wild reckless adventurer, whose very folly proved wiser than the concentrated wisdom of the enemy's council. The most successful exploits were not unfrequently achieved "without money and without men;" while his opponents, many thousands strong, with all Spain at their back, could not succeed in keeping him out of their strongest cities. "A skeleton in outward figure," as Swift says of him, he was capable of the most incredible physical endurance, and seldom indulged in a moment's rest, except when the dark-eyed señoras of Spain lured him for a short hour from his prey. His military daring, his gallantry to the fair sex, and his courtesy to the priesthood, made him a universal favourite with the Spaniards. If they showed resistance, he made them quail by the very wind of his stroke; and once within their gates, he put up his sword, and won the rest by the smoothness of his tongue and the light of his eyes. He relieved Barcelona when greatly harassed by the French by sea and land, and drove the Duke of Anjou out of Spain, with his 25,000 Frenchmen at his back. He soon gained possession of Catalonia, of the kingdoms of Valencia and Aragon, with part of Murcia and Castile, and had prepared the way for Charles making a safe entry into Madrid, which would in all probability have put an end to the campaign, and have secured him his throne. His Majesty, however, put more confidence in his dull German advisers than in the brilliant Earl, who, it must be said, was less obsequious to royalty than those jealous and stupid councillors from beyond the Rhine. Peterborough, who saw that this silliness would cost Charles his kingdom, and undo all that had been already achieved, urged with un-

common patience and devotion the necessity of pursuing an opposite course. But it proved of no avail. The Earl's immoderate vanity had combined with his success in making him be heartily hated by the mean and incompetent; and the foulest lies regarding his conduct had found their way to the ears of his royal mistress in England. Dissensions at length arose among the allied generals. Lord Galway claimed the sole command of the armies in Spain; Stanhope insisted upon offensive measures, Peterborough on defensive; and the disastrous battle of Almanza subsequently proved that the latter was right. Peterborough's counsel was neglected, however, and the prince for whom he had well nigh won a crown, treated him with careless ingratitude. The proud warrior turned his back on the land of his romantic career, and with bitterness in his heart, and a "God preserve any country from the best of German ministers" on his lips, he embarked at Valencia on the 14th May 1706, and bade adieu to Spain. He made his way for Turin, where he remained for some time; but his recall being urgently repeated, he returned to England on the 20th August 1707. Public opinion ran high in his favour on his arrival. Anonymous authors penned extravagant pamphlets in eulogy of him, grave pulpits sounded his praises, and Swift wrote quaint doggrels in honour of "the rambling-est lying rogue on earth." The House of Lords, after much jealousy and a great parade of ceremony, condescended publicly to thank him for his "wonderful and amazing success."

The war, which enriched Marlborough, well nigh beggared Peterborough. The latter hated the Whigs almost as heartily as he did the Tories; and it was considered a great relief to get him despatched for a time to the court of Vienna on some piece of imaginary diplomacy. On his return to London he retired to his residence at Parson's Green, where he gathered round him the leading wits of the day, and gave many "a jovial supper," cooked by his own hands, to Pope, Prior, Lewis, Gay, Friend, and the gruff Dean of St Patrick's, who "loved the hang-dog dearly." In 1709, and a very short time after the death of his two brilliant sons, Peterborough lost his wife, "a lady of admirable wit and judgment," whom he seems to have neglected much more than was meet. After her death he consoled himself for his loss by marrying Anastasia Robinson, a sweet dramatic singer of unblemished reputation, who cherished his declining years with much care. To vary the monotony of married life, he engaged in a sort of Platonic correspondence with Mrs Howard, the mistress of George II., and afterwards Countess of Suffolk, which is still preserved, and is full of much solemn nonsense and lamentably poor verses. His iron constitution had for some time been rapidly giving way, and having undertaken a voyage to Lisbon for the benefit of his health, he died on reaching that city on the 25th of October 1735.

The character of Peterborough, with all its faults and excellences, has not had justice done it. Samuel Johnson said of him once, "he is a favourite of mine, and is not enough known; his character has been only ventilated in party pamphlets." Sir Walter Scott seems also to have taken an interest in his history, as it is known that he was engaged on a Life of the Earl, which he never lived to complete. A highly interesting *Memoir of Charles Mordaunt, Earl of Peterborough and Monmouth, with selections from his Correspondence*, 2 vols., appeared in 1853, from the pen of Eliot Warburton.

MORDEE BAY, on the east coast of the island of Bombay, in Hindustan. The site having been pointed out as an eligible locality for the terminus of the Bombay Railway, a project has been sanctioned for its reclamation from the sea. Lat. 18. 56., Long. 72. 54.

MORE, SIR ANTHONY. See MORO, *Attoni*.

MORE, *Hannah*, an eminent writer of religious and moral works, was born in 1745 at Stapleton in Gloucestershire,

More,
Hannah.

where her father held the humble situation of village school-master. Being afterwards appointed to the parochial school of St Mary Redcliff at Bristol, his daughter gained the intimacy and patronage of Dr Stonehouse, who enabled her to set on foot a flourishing school for boarders and day pupils, which continued to be conducted with great success by her sisters. Her first literary efforts were some poetical pieces, and amongst them was a pastoral drama. Manuscript copies of these effusions were seen and admired by several persons of literary taste and discrimination at Bristol, who strongly recommended their publication. They accordingly appeared; and the drama, which was entitled the *Search after Happiness*, soon became very popular. This flattering reception induced the author to try her strength in the highest walk of dramatic poetry; and she successively brought upon the stage her tragedies of the *Inflexible Captive*, *Percy*, and the *Fatal Falsehood*. Garrick was warmly attached to her; and it was owing in no small degree to the talents of that distinguished player that the second of these compositions was enacted at Drury Lane during fourteen successive nights. Soon after the production of her first tragedy she published two legendary poems, entitled *Sir Eldred of the Bower* and the *Bleeding Rock*, founded upon popular traditions current in Somersetshire. These pieces had very great success, as had also her volume of *Essays for Young Ladies*, which she afterwards expunged from the edition of her works published in 1801, on the ground that the book was superseded by her *Treatise on Female Education*.

In 1782 Hannah More greatly added to her reputation by the publication of a volume of *Sacred Dramas*, to which was annexed a poem called *Sensibility*, much commended by Dr Johnson. In 1786 this indefatigable writer gave to the world two poems—*Florio, a Tale*, and *Bas Bleu, or the Conversation*. The first is a respectable and not ill-natured satire on the frivolous manners of the young gentlemen of the period. The second, also a satire, is directed against the Blue-Stocking Club, which met at Mrs Montagu's in Portman Square, and was so called from one of the members, Mrs Jerningham, always wearing stockings of a blue colour. Other works successively proceeded from her pen. Of these the principal are,—a *Poem on the Slave Trade*, printed in 1788; a tract entitled *Thoughts on the Manners of the Great*, which appeared the same year; *An Estimate of the Religion of the Fashionable World*, published in the year 1791, and esteemed one of her best productions; *Remarks on the Speech of M. Dupont in the National Convention on Religion and Education*; and further, with the view of opposing the propagation of sedition and infidelity, she, in 1795, commenced at Bath the *Cheap Repository*, which was published in monthly numbers, and contained several very pleasing tales. This periodical obtained a very wide circulation, and was said to have had considerable effect in calming the public mind, then agitated by the doctrines so prevalent in France.

Hannah More now removed from Bristol to Cheddar, where the ignorance and destitution of the place having deeply affected her, she opened a number of schools for educating the poor children and alleviating their misery. Her benevolent designs were at first strenuously opposed; but she ultimately succeeded in establishing a number of schools, not only at Cheddar, but all round the Mendip Hills; and the good effects which they produced soon became apparent. In 1799 appeared her *Strictures on the Modern System of Female Education*, three editions of which issued from the press during the same year. This work was censured by some of the critics as too austere; but notwithstanding this circumstance, she was called upon by the highest personages in the realm to put her sentiments in writing on the proper course of instruction to

be adopted for the infant heiress to the British throne. She set diligently to work at the command of royalty, and produced in 1805 a work in two volumes, entitled *Hints towards forming the Character of a Young Princess*. It gave high satisfaction generally; but offence was taken in one quarter, and much abuse was in consequence poured upon it. In the year 1809 was published *Catechs in Search of a Wife*; two years afterwards appeared *Practical Piety and Christian Morals*; in 1815 came out an *Essay on the Character and Writings of St Paul*—an attempt more ambitious than successful; and in 1819 her literary career terminated with the publication of *Modern Sketches*. She was now aged and infirm, but still continued to take a great interest in the welfare of charity schools, bible and missionary societies, and other benevolent and religious institutions. Her piety supported her in her later afflictions; and she expired with the composure, and full of the hope and faith, of a Christian, on the 7th of September 1833. She is said to have realized L.30,000 by her works, a very considerable proportion of which she bequeathed to religious and benevolent societies.

The works of Hannah More have always been highly esteemed by the religious world, and she is generally considered as one of the most distinguished of that class of writers who unite great piety with considerable literary talent, and dedicate the creations of fancy as well as the deductions of reason to the service of religion. Her poetry is not much prized, except by a select few, for the piety and sound judgment which it displays. Her prose is justly admired for its sententious wisdom, its practical good sense, its masculine vigour, and the dignified religious and moral fervour which pervades it. *Catechs* passed through six editions in one year; and since its first appearance it has frequently been reprinted, besides being translated into several foreign languages. A collected edition of her works has been published in 11 vols.; and *The Memoirs and Correspondence of Mrs H. More*, by W. Roberts, were published in 4 vols. 8vo, 1834. A new and abridged edition of this Life, with selections from her correspondence, 12mo, appeared in London in 1856.

MORE, Henry, an eminent English philosopher and divine, was born at Grantham in Lincolnshire on the 12th October 1614. His father, Alexander More, a gentleman of property in that county, was a staunch Puritan, and educated his family in the strictest principles of Calvinism. At the age of fourteen, Henry was sent to Eton, with many affectionate charges to stand fast to the principles of his hereditary creed. Young More, however, who had always been of a retiring and thoughtful disposition, had already secret misgivings as to the soundness of the predestinarian doctrine; and now that he no longer breathed the Calvinistic atmosphere at home, he gave freer scope to his speculative tendencies. While the Eton boys bounded after the ball, Henry More "with his head on one side, and kicking now and then the stones with his feet," was dimly working his way to the bold conclusion that the doctrine of predestination was inconsistent with the justice and goodness of God. He was, moreover, prepared to maintain this position at all hazards; and with characteristic ardour and genuine speculative courage, he stoutly disputed the question with his elder brother, who, in company with his uncle, shortly afterwards visited him at Eton. This uncle of his, who was a blunt, matter-of-fact sort of man, and who believed more in the rod than in the reason, threatened the young heretic that if he did not give over these immature philosophizings, he would subject him to a wholesome course of corporal punishment. Henry of course did not give over his speculations, but continued to vex his young brain with quite insoluble problems. He seems, however, even in those boyish years, to have been remarkable for sincerity and humble purity of heart. At the advice of his uncle—

More,
Henry.

More,
Henry.

who seems to have monopolized the direction of his education—he was, after a three years' residence at Eton, removed to Christ Church, Cambridge, in 1631, just a year before John Milton left it. Here the young philosopher displayed an extraordinary thirst for knowledge, and read eagerly the works of Aristotle, Cardan, Julius Scaliger, and other thinkers of that class. But such writers could not satisfy his longings for higher light. They made him more sceptical than when he began; and renouncing the guidance of the logicians for ever, he directed his attention to the Platonic writers and mystic divines, and discovered the long-looked for treasure in the dreamy pages of Marsilius Ficinus, Plotinus, and Trismegistus. "That golden little book," ascribed to John Tauler, the *Theologia Germanica*, "pierced and affected" him more than all the rest. The simple knowledge of phenomena no longer had any charm for him; he sought for the proper food of the soul among those archetypal ideas which were believed to lie behind all sensible objects. He learned to think away all objects of sense, and strove with his "illuminated" teachers to live alone with God in a supersensible world. The earthly body, however, clogged the upward progress of the spirit; and what he gained in fancied illumination he lost in bodily strength. After a few years practice of this course, the poor youth found himself reduced to a very skeleton, and from his strange talk about "particular experiences," his friends began to charge him with enthusiasm. Some idea may be formed of his state of mind during this period from his philosophical poem called *Psychozoia, or the Life of the Soul*, published in 1640. He took the degree of Master of Arts in 1639; and on being chosen a fellow of his college, he became tutor to several persons of distinction, and among others to the brother of Lady Conway. At the request of this lady, who was a noted disciple of William Penn, More wrote, among other treatises, the *Conjectura Cabalistica*, and the *Philosophia Teutonice Censura*; and if he did not succeed in converting her from Quakerism, he at least secured her friendship, and at her death a legacy of £400, which the benevolent mystic devoted to purposes of private charity. If ever man strove to be true to the light that was in him, it was Henry More. He repeatedly declined the most flattering offers of church preferment, choosing rather to linger about the quiet halls of Christ Church, and muse as he listed, than enjoy the honours of a bishopric at £1,600 a year. The rectory of Ingoldsby, which had been purchased for him by his father, he resigned in 1642, and afterwards presented it to his college. He even declined the mastership of his own college in 1654, when the celebrated Cudworth was appointed; and if he accepted a prebend in the church of Gloucester in 1675, it was only to make it over to his friend Dr Fowler. Not that he lightly regarded the wants of his country. He is said to have wept over its miseries. But he believed himself to be more in his proper sphere using his pen in studious retirement, than mingling with the busy turmoil of the world. He was no doubt a little of the "intellectual epicure," as Norris of Bemerton called him; but yet his pen was constantly occupied in behalf of what he judged the cause of religion and virtue. He engaged in a correspondence with Descartes during 1648–9; and three of More's letters, with the replies of the French philosopher, are still to be read at the end of most editions of Descartes' works. More had a great esteem for Descartes, and judging from those letters, the admiration must have been mutual. Not that the English Platonist began with Cartesianism and ended with mysticism, as Cousin in his hasty generalization (*Cours de l'Histoire de la Philosophie*, Leçon 12me) seems to convey. On the contrary, while More always admired the Cartesian philosophy as "a fine, neat, subtle thing," he constantly maintained that "for the true ornament of the mind, it bears no greater proportion to that principle I told you of

More,
Henry.

[viz., the divine sense], than the dry bones of a snake made up elegantly into a hat-band is to the royal clothing of Solomon." More pursues a still more passionate and unjust strain of invective against Cartesianism in his *Enchiridium Metaphysicum*, published in 1671. In this work we obtain a more profound and methodical view of More's metaphysical system—if system it can be called—than in any of his other writings. Metaphysics, according to him, is the science of incorporeal existence, and admits naturally of a two-fold division. The one demonstrates the existence of other substances than bodies; the other determines the essence and principal attributes of those substances. His proof of the existence of immaterial things is threefold: first, space, which contains all matter, cannot be itself material; secondly, matter is contingent, for it is possible to think it away, while space is necessary, no such abstraction being possible for it; thirdly, the general series of natural phenomena come and go, begin and end, ceaselessly change, in a word, are contingent; but this supposes some necessary existence beyond the sphere of the sensible world, from the bosom of which the contingent emerges. In attempting to demonstrate the latter position, More ranges over all the sciences with the ease of a master, displaying a knowledge at once extensive and profound. As a speculator, More was perhaps more of the eclectic than the mystic, but his thoughts always gravitated towards mysticism, and found their last expression there. After his own doctrines, More preferred Descartes' to all others; just as Hobbes is said to have preferred More's system to every one but his own. Indeed, the extravagant admiration which More always showed for his own conceits and fancies, no matter how groundless, stood in marked contrast with his acknowledged learning, charity, and humility. His allusions to himself and his own productions in the *prefatio generalissima* to the Latin edition of his works, and elsewhere, betray more than a mere amiable egotism,—they savour much more of personal vanity. More, however, while sometimes extravagant, seldom falls into the rude fervour or weak sentimentalism of the ordinary mystics, and has always the good sense and proper feeling to avoid the gross profanity which often characterized the English mystics of that age. He even wrote an express treatise in 1656, entitled *Enthusiasmus Triumphatus*, in which he traces the nature, causes, and cure of enthusiasm, and concludes by ascribing this abnormal state of mind mainly to bodily causes. If he was sometimes credulous, he was very generally shrewd and sagacious; and with all his defects, he unquestionably occupies a high place among that bright though small constellation of thinkers known as the English Platonists of the seventeenth century. Some of his books seem to have met with an extensive sale. *The Mystery of Godliness* was said by a London bookseller to have "ruled all the booksellers" for twenty years. Yet the appreciation which they met with did not quite satisfy their author, and he seems to have occasionally appealed to that "perspicua et pacifica posteritas"—that wise and peaceful posterity—which is to remodel the temple of fame. The young could not understand him, and the old thought him mad. Yet his merits were duly appreciated by such men as Cudworth and Norris. Three hundred pounds were left by an admirer to have some of More's pieces translated into Latin; a circumstance which induced the author to publish the whole of his works in Latin in three folio vols. in 1679. After completing this task, he does not seem to have written any work of importance. His last work was the *Medela Mundi, or Cure of the World*, which he did not survive to finish. His health had never been robust, and in 1686 he was seized with a fever, from the effects of which he never recovered. He died on the 1st September 1687, in the seventy-third year of his age. Besides the complete Latin edition of More's works already referred to, the greater number of his productions

More, Sir Thomas, appeared in English, under the title of *A Collection of several Philosophical Writings*, folio, London, 2d ed., 1662, and 4th ed., 1712. *The Life of the Learned and Pious Dr Henry More*, 8vo, London, 1710, was written by the Rev. Richard Ward, an enthusiastic and not very discriminating partisan of More's system. (See also the *Biographia Britannica*, the *Dictionnaire des Sciences Philosophiques*, and *Hours with the Mystics*, by R. A. Vaughan, 2 vols. London, 1856. A detailed list of Dr More's works will be found in Watt's *Bibliotheca Britannica*.)

MORE, Sir Thomas, the greatest Englishman of his day, was the only son of Sir John More, one of the judges of the King's Bench, and was born in 1480 at Milk Street in the city of London. His first lessons were received from Nathaniel Holt, an eminent schoolmaster of that day in Threadneedle Street. It was at that time a custom with genteel parents to allow their sons, for the benefit of their training, to serve as pages to the nobility or to the high dignitaries of the church. More was accordingly placed, about his fifteenth year, in the family of the aged Cardinal Morton, a man of great wisdom, learning, and virtue. His residence there seems to have been both pleasant and profitable. He daily heard, as he waited at table, the conversation of the noble and learned guests that frequented his master's board. During the merry-makings of Christmas, when the household was assembled to witness the rude plays peculiar to the season, he was wont to step up among the players, form a character for himself on the suggestion of the moment, and delight the audience by his extempore jests. The old cardinal was charmed with the lively and ingenuous wit of his young ward. He was fond of pointing him out to his visitors, and of remarking that "that child would prove a marvellous rare man."

In 1497 More entered the university of Oxford as a student of Canterbury, a college which was afterwards abolished to make room for Christ Church. His whole appearance and bearing at that time were peculiarly fitted to prepossess men in his favour. He had a well-proportioned figure, of a middle stature; his small gray eyes twinkled with innocent pleasantry; and his countenance beamed with good nature and benevolence. In a short time Grocyn, Linacre, and William Latimer, three of the most learned men of that day, had drawn towards him. Erasmus, too, who was then sojourning at Oxford in the height of his fame, would often leave the company of his eminent and aristocratic admirers to visit the young student of seventeen, in his solitary rooms in St Mary's Hall. The heart of the great scholar was touched with an affection almost womanly for the youthful Englishman, and a friendship sprung up between the two which all the toils and troubles and wanderings of after years could not impair. In the society of such men the susceptible nature of More could not fail to catch a noble ardour for learning. The scanty means of support to which he was restricted by his prudent father kept him back from the haunts of idle indulgence and dissipation. All his time was therefore devoted to his intellectual culture. He became an enthusiastic student of the Greek language, which was then slowly forcing its way amid much opposition to a place among the regular studies at Oxford. He composed Latin epigrams, both witty and sentimental. He also resolved his hard and rugged mother-tongue into the soft and flexible forms of poetry, and wrote many English verses sparkling with harmless quips and merry conceits.

After completing the ordinary curriculum at Oxford, More studied law first at the New Inn and then at Lincoln's Inn. He was subsequently appointed to lecture at Furnival's Inn on jurisprudence, and at St Lawrence's church on Augustine's *De Civitate Dei*. About this period a bitter-remorse for his youthful sins began to haunt and torment his soul. That he might take refuge, as it were, in a holy atmosphere, he fixed his abode near the great Carthusian

monastery called the Charterhouse, and daily attended the spiritual exercises of the priests. Every form of penance was also employed for mortifying the flesh. He kept Fridays and high fasting-days with severe austerity, and began to wear a shirt of hair next his skin. He often flung himself down to sleep on the cold floor, or on a bare settle, with a hard log under his head, and woke up after four or five hours' repose to watching and prayer. As the last stroke in this process of self-crucifixion he was meditating to consecrate his life to the priesthood, when an event occurred which diffused a sunshine over his gloomy condition and still gloomier prospects. A certain Mr Colt, a hospitable country gentleman, and the father of a family of daughters, was wont to invite the young lawyer to spend his holidays at the mansion of Newhall in Essex. More became fascinated with the artless and pious conversation of the young ladies, and thought of making one of them his wife. His taste would have led him to choose the second of the sisters; but his sympathetic heart shrunk from seeming to slight her who had a claim to his preference by her priority of birth, and so he married the eldest.

Towards the close of the reign of Henry VII. More had risen into professional eminence. There was scarcely an important case brought before the courts in which he did not appear as one of the counsel. He also held the honourable office of judge of the Sheriff's Court in the city of London. His merit was recognised about the same time by his being appointed a Burgess in the Parliament which the King had summoned in order that he might obtain a grant of three-fifteenths for the marriage of his eldest daughter with the King of Scotland. It was then that More became, as Sir James Mackintosh asserts, the restorer of political eloquence. For this noble achievement the qualities of both his head and heart peculiarly fitted him. A moral courage unsurpassed for its serene dignity was supported by a ready power of thinking, an equally ready command of language, a polished wit that could wound deeply but not harshly, and a tone of speech that could conciliate an opponent without sacrificing a single opinion. Accordingly, no sooner was the royal demand laid before the House, than he stood forth to oppose it in a vigorous and eloquent speech. The silent and timorous burgesses, while astonished at the unwonted voice of opposition that sounded so boldly through the Parliament-hall, responded to the appeal of the orator, and refused the request of the King. Henry heard with indignation that "a beardless boy had disappointed all his purpose." He resolved to be revenged. But as the young offender had no possessions upon which the avaricious King might seize, old Sir John More, on some pretext, was cast into prison, and fined L.100.

About 1509, the year of the accession of Henry VIII., all the available time of More was engrossed with his professional avocations. Yet in the few hours stolen from sleep his studies were diligently prosecuted. His attention was chiefly directed to the composition of *The Life and Reign of King Edward V.* This was the first history of England written in the vernacular, and it was also the first specimen of real classical English prose. It therefore forms no ordinary landmark in the annals of the literature of England. One of its more marked characteristics is the easy, sweet, and spirited flow of the narrative,—a striking type of the author's own disposition. More had scarcely finished this work in 1510, when he was appointed undersheriff of London. In the same year he received a visit from his friend Erasmus. The household scene which the eminent scholar then saw, and which he afterwards described, was a perfect picture of domestic felicity. More's first wife had died, leaving one son and three daughters. A widow—elderly, shrewish, and worldly—had succeeded to her place. Yet even she proved no obstruction to the well-ordered domestic routine. In the morning the inmates

More,
Sir Thomas

More, of the house knelt together round the family altar. Then they busied themselves with studies, reading, or the quiet and cheerful discharge of more special duties. In the evening the head of the house returned to chat with his family round the hearth. His very presence diffused harmony and good order. The impatient exclamations and worldly saws of "Mistress Alice," as he called his wife, were drowned in a flood of merry jests; the studies of his children were stimulated by an overflowing kindness; and the lessons of virtue and piety were inculcated by quaint and pleasant similes. He also spoke a kind and fatherly word to his servants, and saw that they were maintaining their good character. The day was then closed, as it had been begun, with family devotion.

Such domestic felicity filled the soul of More, and expelled from it every hankering after political preferment. There was also a wariness fitting in exactly with the other parts of his well-balanced character, which kept him back from climbing the unsteady ladder of ambition. Accordingly, the attempts which were made at the beginning of the reign of Henry VIII. to entice him into the service of the state were all in vain. Even after he had been employed in two embassies to the Netherlands, in 1514 and 1515 respectively, he returned immediately to his privacy, and refused the pension by which the King sought to buy his services. At length, in 1516, More was persuaded to venture into the arena of politics, and was elected a member of the Privy Council. The favours with which he was immediately loaded prevented his speedy retreat. The King became excessively fond of the company of his new councillor. On days of council he consulted with him, and on holidays he jested with him. In his grave moods he conversed with him on theology. When the nights were clear he took him up into the leads to observe the courses of the planets, and to discourse about astronomy. Then he would take him down to a private supper, and would crack jokes with him far on into the night. Even when the courtier had contrived to throw off these encumbering favours for a while, and thought himself safe in the bosom of his family at Chelsea, the King would drop unexpectedly in to dine. After dinner he would walk in the garden in deep consultation, with his arm round his favourite's neck. These great honours would have completely intoxicated the majority of men; but they did not even affect the strong head of More. His clear eye detected the bloated selfishness from which they all proceeded. "If my head," said he at that time to his son-in-law Roper, "would win the King a castle in France when there was war between us, it should not fail to go." Therefore, instead of dwelling upon the preferment which the royal kindness portended, his mind was quietly engaged in the composition of his *Utopia*. This work, written in good Latin, was published at Basle in 1518, became speedily popular among the scholars of France and Germany, and was soon afterwards translated into French, Italian, Dutch, and English. It is a description of the laws and customs of an imaginary island of America, feigned to have been discovered a short time previously. Of the principles of polity described many are wildly chimerical, some are plausible, and others are just. At first sight the book appears to be nothing else than a freak of the author's fantastic and exuberant fancy. There is a likelihood, however, that it has a hidden character. At this time the large mind of More cherished several wide and catholic opinions—such as the principle of religious toleration—which were obnoxious to the spirit of the age. To profess these sentiments openly would have been to dare the unscrupulous vengeance of Henry. It is probable, therefore, that in accordance with his ordinary custom of uttering a grave truth in the garb of a gay jest, he employed the cunningly-devised romance of *Utopia* for a cover to his earnest political opinions.

More had entered on the road to preferment, and he was now carried rapidly forward. A knighthood and the office of treasurer of the exchequer were conferred upon him in 1521. About the same time, greatly against his taste and home-feelings, he was employed in the artful negotiations which Wolsey carried on with France. In 1523 the Parliament that was then convoked elected him to be their speaker. On this occasion he stood forth once more as the restorer of political oratory and the champion of parliamentary freedom. The grant of a very heavy subsidy had been demanded from the House by the government. That the members might be awed into compliance, Cardinal Wolsey appeared with all his attendants and insignia, and made a solemn speech in support of the subsidy. The burgesses replied to it by a dogged silence. At length the speaker was demanded to return an answer for the rest. After calmly vindicating the ancient liberty of the Parliament to speak or to be silent, Sir Thomas More, with all due reverence, said, that though the members had entrusted him with their voices, yet they had not entrusted him with their heads, and therefore he could not answer his grace in so weighty a matter. The cardinal hurried from the House in a great rage against the speaker; yet the King, in spite of this thwarting of his wishes, continued his favour toward Sir Thomas, and in 1526 appointed him chancellor of the duchy of Lancaster. It was about this time that More began to occupy himself specially with the controversies against the Reformers. His attachment to that old form of religion through which he had derived so much pious comfort, and his natural love of peace and good order, made him cling fast to the sinking cause of Popery. Accordingly, mustering all his learning, wit, and acuteness, he set himself industriously to wage a war of pamphlets against Luther, Tindal, and other Reformers. The excitement of debate hurried him into an exaggeration of statement, and a bitterness of feeling, into which he had never fallen before; yet perhaps he was as fair and as charitable as any other writer that ever ventured on this same irritating controversy.

In 1527 Henry VIII. began to search for reasons for divorcing Queen Catherine. The opinion of Sir Thomas More, who stood so high in the estimation of the country and of Europe in general, was especially desirable. He was therefore sounded on the great subject that was perplexing the public mind. To advocate the divorce would have been to offend his conscience; to condemn it would have been to offend his liberal benefactor the King. He therefore evaded returning a direct answer. But Henry was not to be diverted, and resolved to overwhelm the scruples of his favourite by a great benefit. Accordingly, on the 25th October 1529 More was raised to the position of lord chancellor, that high and giddy seat from which Wolsey had just fallen. The duties of his new office were performed with all his native benevolence and unpretentious industry. He sat daily in his own hall to receive the petitions of the poor; he kept his hands clean from bribes; and, without being cruelly intolerant, he did his utmost to suppress heresy. But this conscientious performance of duty was not all that was expected by his royal master. His opinion on the divorce was repeatedly demanded. Again and again did More reply that he was neither worthy nor willing to be his Majesty's adviser. At length, foreseeing that he would soon be required, in his official capacity, to countenance the King's marriage with Anne Boleyn, he resigned the great seal in May 1532.

Sir Thomas More laid aside his robes of office as poor a man as when he had put them on. The establishment at Chelsea, in which, like a patriarch of old, he had gathered all his children and grandchildren under one roof, was immediately broken up. His sons and daughters went to their several homes. He himself retired to the chapel in his garden to prepare his soul by meditation and devotion

Moreau.

for the storm that was coming in the distance. It soon came. Commissioners arrived to exact from him an assent to the King's recent marriage. They first tried to wheedle him, by reminding him of the royal favour towards him. But his conscience accused him of no ingratitude. They then tried threatenings. "Terrors are arguments for children, not for me," replied he, placidly. At length, in 1534, the act of succession for securing the throne to the issue of Anne Boleyn was passed. More was demanded to assent to it by an oath. He refused to swear, and declined to give any reasons for his refusal. Four days afterwards he was lodged in the Tower. There he lay for more than a year, resisting calmly every attempt to break his resolution, receiving the visits of his friends with his usual outflow of quaint and pious apophthegms, and writing devotional treatises and letters to his favourite daughter, Margaret Roper, with fragments of coal. On the 1st July 1535 his trial came on. He was indicted under the act of supremacy passed towards the close of 1534, for constituting the King supreme head of the church. His refusal to swear to this act was declared high treason, and he was condemned to death. On the 6th July he appeared on the scaffold in that same jesting humour which was a part of his nature. His head was already on the block, when he desired the executioner to stop until he had removed his beard, "for that," said he, "hath committed no treason." The next moment the fatal blow fell.

The best English translation of the *Utopia* is that of Bishop Burnet. More's English works were published at London, 1557, and his Latin works at Louvain, 1556. There are Lives of More by his son-in-law Roper, 8vo, 1626; Hodgesden, 8vo, 1652; his great-grandson Thomas More, 4to, 1726; and Sir James Mackintosh, 1844.

MOREA (anc. *Peloponnesus*) forms the southern part of Greece, and one of the three great divisions of that kingdom. It extends in N. Lat. from 36. 23. 20. to 38. 26. 4., and in E. Long. from 21. 5. to 23. 29., being 7920 square miles. (See GREECE.)

MOREAU, JEAN VICTOR, one of the greatest generals of the French revolution, was born at Morlaix in 1763. He was the son of an advocate who had destined him for the same profession, but having early contracted a decided predilection for the army, he enlisted in a regiment, in which he served for a short time, until his father purchased his discharge, and sent him to resume his studies. He did so with considerable success, and at length became *prévôt de droit* at Rennes, where he exercised a sort of supremacy over the students, by whom he was greatly beloved. In 1787, when the ministry wished to effect a revolution in the magistracy, he joined in resisting the attempt; and having figured in the early troubles as chief of the youth of Rennes, he was called "the General of the Parliament." At the commencement of the revolution he raised a company of volunteer gunners, of which he became captain; and having organized and instructed it, he continued to serve in the same capacity until the year 1792, when he enrolled himself in a battalion of volunteers which was then setting out to join the army of the north. He made his first campaign under Dumouriez, as commandant of a battalion. In 1793 he became general of brigade, and the following year he was promoted to the rank of general of division, on the recommendation of Pichegru, who immediately confided to him a corps destined to act in maritime Flanders. Moreau took possession first of Menin, then of Bruges, Ostend, Nieuport, the island of Cassandria, and lastly of Sluys, which capitulated on the 26th of August. At the moment when he made this conquest for the republic, the revolutionists of Brest were sending his aged father to the scaffold as an aristocrat. This venerable old man, whom the people of Morlaix called the "father of the poor," had undertaken to manage the property of some emigrants; and this was

employed as a pretext to destroy him. Moreau had already become disgusted with the revolutionary system, and such an event naturally increased his detestation. He conceived that he had no longer any country but the camp, nor any home but his tent in the field.

Moreau.

He commanded with great distinction the right wing of the army of Pichegru during the celebrated winter campaign of 1794; and when that general assumed the command of the army of the Rhine and Moselle, Moreau was promoted to the command of the army of the north. After the retreat of Pichegru, he placed himself at the head of the army of the Rhine and Moselle, and in the year 1796 opened that campaign which became the foundation of his military fame. Having driven back Wurmser towards Mannheim, he effected the passage of the Rhine near Strasburg, attacked the Archduke Charles at Rastadt, forced him to abandon the course of the Necker, and on the 11th of August fought a battle near Heydenheim, which lasted seventeen hours. The Austrians having retired on the Danube, Moreau advanced and soon found himself opposed by General Latour, who was daily receiving reinforcements; but believing himself supported by the diversion, or rather the parallel invasion of Jourdan towards Ratisbon, he continued his forward movement. The discomfiture and retreat of Jourdan, however, disconcerted all his combinations, and leaving his flank completely uncovered, obliged him to retire. This retreat commenced on the 11th of September, and though severely criticized by Napoleon, is unquestionably one of the finest operations of the kind recorded in the history of war.

At the opening of the next campaign in 1797, Moreau effected the passage of the Rhine in the face of the enemy ranged in order of battle upon the opposite bank. The immediate consequences of this brilliant action were, the surrender of the fort of Kehl, and the capture of nearly 40,000 prisoners, besides several standards. Owing to some misunderstanding with the executive directory relative to his old friend Pichegru, Moreau was obliged, on the 7th September 1797, to resign, and to shelter himself in retirement. He remained comparatively unemployed until April 1799, when the misfortunes which had attended the recommencement of war rendered his talents necessary. Moreau was therefore sent to Italy, where he superseded Schérer in the command of the army. On the 11th of May he repulsed the Russians near Bassignano, and then passed the Bormida; but being assailed by the greater part of the forces under Suwaroff, he was obliged to evacuate Valentia and Alessandria.

Moreau had just been appointed to the chief command of the army of the Rhine, when Joubert arrived to replace him in that of Italy. Being on the point of fighting a battle,—which, by the fall of Mantua and the junction of Kray with Suwaroff, had become inevitable,—Joubert wished to leave the direction of it to him; but he refused, and begged permission to combat under the orders of the new chief of the army. At this battle, which was fought at Novi, and in which Joubert fell, Moreau ran the greatest risks, having had three horses killed under him, and his uniform pierced by balls. After a fierce conflict, the French army was defeated; but Moreau conducted his retreat with so much superiority that he almost nullified the victory which the allies had gained.

On the arrival of Bonaparte, who had escaped from Egypt, Moreau consented to serve under the orders of that general, and by his influence and means to promote the revolution which was then preparing. But scarcely had it been effected at St Cloud, on the 9th of November 1799, when he saw reason to apprehend that he had concurred in giving a tyrant to his country. Being almost immediately called to assume the command on the Rhine and the Danube, he introduced several important changes into the constitution

Moreau. of the army. His plan was not approved by Bonaparte, who, thinking only of reconquering Italy, wished to make the army of the Rhine merely an army of observation. But Moreau stuck firmly to his plan, and resisted. Napoleon felt greatly offended; and this dispute as to the co-operation of the two armies proved the germ of that mutual hatred which sprung up between these celebrated rivals, and which was probably one of the causes of their common ruin. Napoleon saw it necessary, however, to yield, and to leave to Moreau all the honour of the conception of the plan of campaign, and all the means for carrying it into execution.

The success of the campaign which ensued was throughout decisive. He encountered the enemy, first at Stockach, where he defeated him, and then fought successively the battles of Engen, Moeskirch, and Biberach, in all of which he was victorious. Those victories gained by Moreau facilitated the conquest of Italy; and he even detached a corps of 12,000 men to reinforce the army of the First Consul. Finding, however, that neither his demonstrations nor his rapid incursions into Bavaria, could induce Marshal Kray to quit his unexpugnable position at Ulm, Moreau advanced beyond the Lech, attacked the Austrians along their whole line, crossed the Danube at Blenheim, and in the plains of Hochstadt, obtained, by similar manoeuvres, on the 19th of June, an advantage similar to that which Bonaparte had gained at Marengo only three days before. Kray having at length abandoned his position at Ulm, Moreau marched in pursuit of the marshal, whom he once more vanquished at Neuburg; he then entered Bavaria, again defeated the Austrians at Landshut, and only suspended his operations after having caused them to sign, on the 15th of July, the armistice of Parsdorf.

This suspension of arms continued until the end of November, when Moreau was attacked by the Archduke John with an army of Austrians amounting to 120,000 men. Moreau retreated from the banks of the Inn, and continuing his movement on Hohenlinden, succeeded in drawing the enemy into the defiles near that place. The moment for striking a blow had now arrived. Accordingly, on the 3d of December 1800 was fought that bloody and decisive battle, in which there was not a French corps that did not come into action and cover itself with glory. Eleven thousand prisoners and 100 pieces of cannon fell into the hands of the victors. More than 6000 Austrians remained on the field of battle, whilst the loss of the French did not exceed 2500 men killed and wounded. To the congratulations of his generals, Moreau replied by attributing to them the principal share in the glory of the day, adding at the same time, "My friends you have conquered peace."

The archduke having taking refuge behind the Inn, Moreau pursued him without intermission, gained another victory at Lauffen, and having passed the Salza, occupied Salzburg; and, continuing his advance, carried terror to the gates of Vienna. Nor did he suspend his march until the Archduke Charles, who had been again placed at the head of the imperial army, announced to him that the Emperor had resolved to make peace, whatever might be the determination of his allies; and this declaration served as the basis of the armistice of Steyer, signed on the 25th of December. This campaign of twenty-five days placed Moreau in the rank of the greatest captains, and entitled him to the homage of public admiration, which was paid to him on his return to Paris. Bonaparte presented him with a pair of pistols magnificently mounted, observing that he had wished to have had his victories engraved on them, but found that there would not be room. Despite this show of personal admiration, Napoleon could not forgive the success of Moreau, and especially the affection with which he was regarded by his officers. Moreau, who was deficient in civil prudence, acted in such a manner as to in-

crease the suspicion with which he was regarded. His house became the rendezvous of persons avowedly inimical to the consular government; and he was by imperceptible degrees drawn into that fatal connection with Pichegru and his associates which eventually proved the cause of his ruin. (The particulars of this affair, with the arrest, imprisonment, trial, and sentence of Moreau, will be found narrated in the historical portion of the article FRANCE.) On the 10th of June 1804 he was sentenced to two years' detention, which, by the influence of Fouché, was commuted into permission to travel, on condition that he should retire to the United States, and not return to France without the leave of Bonaparte. He accordingly set out for Spain, escorted by gendarmes, and in 1805 embarked at Cadiz for the United States, where he resided for about eight years, beloved and respected by all who knew him.

After the disasters which befel the French grand army in the retreat from Moscow, the Emperor Alexander, aware that he had no general capable of contending with Napoleon, made secret overtures to Moreau; and the latter having decided to embrace the offers of the Czar, and join him in the approaching contest, embarked on the 21st of June 1813 with M. de Svinine, chancellor of the Russian embassy, and on the 24th of July entered the port of Gottenburg. At Stralsund he passed three days with his old companion in arms Bernadotte, then Crown Prince of Sweden, and having concerted with him the plan of the ensuing campaign, proceeded to join the allied sovereigns at Prague, where, as might have been expected, he was received in the most flattering manner.

The plan of the allies consisted in debouching from Bohemia with their grand army, in order to turn and attack Dresden, which formed the pivot of Napoleon's operations. The attack commenced on the 26th of August, and was resumed the following day, when Moreau, having advanced to observe a movement of the French, was struck by a cannon-ball, which fractured the knee of the right leg, and, passing through, carried away the calf of the left. He fell into the arms of Colonel Rapatel, exclaiming, "I am done for, but it is pleasant to die in so good a cause." Being removed to an adjoining house, he there underwent amputation of the right leg, and the same operation was performed on the left, which had been too much shattered to admit the possibility of its being saved. In this horribly mutilated condition, the allied army being now in full retreat, he was transported as far as Laun, where he lingered in agony till the morning of the 2d of September, when he expired. At the time of his death he had prepared for publication a proclamation to the French, which the Emperor Alexander had approved, and in which he explained the object of his return to Europe,—the most questionable act of his life,—namely, to assist the French in emancipating themselves from the despotism of Bonaparte, and to sacrifice his life, if necessary, to restore prosperity to his country, all the true sons of which he invited to rally round the standards of independence. As a warrior, Moreau was superior to all the generals of the Revolution, Napoleon excepted; he combined the caution of Fabius with the cool determination of Turenne; in every succeeding campaign his genius shone forth with increased splendour; and his last achievement at Hohenlinden exhibited a union of scientific combination with precise and vigorous execution which has seldom been equalled and never surpassed. (J. B.—E.)

MORECAMBE BAY, in England, separates Lancashire into two parts, and washes the coast of Westmoreland, where it receives, by a wide estuary, the River Kent. The bay is very shallow; and at low water a large extent of sand is left dry, and may be crossed without danger or difficulty.

Morell
||
Morelli.

MORELL, ANDRÉ, an eminent antiquary, was born at Berne, in Switzerland, on the 9th of June 1646. He turned his attention early to the study of numismatics, and in 1680 he went to Paris, where his reputation procured him admission into the society of the learned, and where, in 1683, he published *Specimen Universæ Rei Nummarie Antiquæ*, a second edition of which, corrected and enlarged, appeared at Leipsic in 1695. The encouragement which was originally held out to him in Paris was not confirmed; and after being imprisoned for three years in the Bastille for the heinous offence of claiming the remuneration promised him as joint-keeper of the Royal Cabinet of Medals, he went to Germany in 1694, on the invitation of Count de Schwartzburg-Arnstadt. Here he prosecuted the preparation of a great work on numismatics, but his labours were closed by death in 1703. Havercamp having collected and arranged his scattered materials, published, in 1734, *Thesaurus Morellianus, sive Familiarum Romanarum Numismata Omnia*, in 2 vols. folio; and, in conjunction with Schlegel and Gori, published in 1752, from Morell's MS., the *Thesauri Morelliani Numismata Aurea, Argentea, Ærea, cujusque moduli xii. priorum Imperatorum*, Amsterdam, in 3 vols. folio.

MORELL, Thomas, an eminent classical scholar and editor, was born at Eaton, in Buckinghamshire, on the 18th of March 1703. Having graduated at King's College, Cambridge, he was appointed curate of Kew in 1731, and for some time officiated in the same capacity at Twickenham. In 1737 he was made rector of Buckland; and in 1775 we find him acting as chaplain to the garrison at Portsmouth. He died on the 19th of February 1784. His principal works are,—*A Collection of Theological Poems, original, and translated from the Latin of Vida*, with notes, London, 1732-36, in 8vo; an edition of Chaucer's *Canterbury Tales*, with modern imitations, London, 1737; an edition of the works of Spenser, 1747; the *Hecuba, Orestes, Phœnissæ*, and *Alcestes* of Euripides, with ancient scholia and notes, London, 1748; an English translation of the *Hecuba*, with annotations; the *Prometheus* of Æschylus, with scholia, notes, and an English translation in blank verse, 1767; *Two Letters on Greek Inscriptions found upon an altar at Corbridge in Northumberland*; editions of the *Greek Lexicon* of Hederick, and of the *Latin Dictionary* of Ainsworth; *Thesaurus Græcæ Poëseos, sive Lexicon Græco-Prosodiacum*, Eton, 1762, in 4to, an imitation of the *Gradus ad Parnassum*, since considerably enlarged by Dr Maltby; Cambridge, 1815; and various other works, particularly Annotations on Locke's *Essay*, 1793, 8vo.

MORELLA, a town of Spain, in the province of Castellon-de-la-Plana, is situated on the S. slope of a mountain, 45 miles N. of Tortosa. It is surrounded by Moorish fortifications, and on the top of the hill stands a strong castle, with a Moorish tower. The streets are steep and irregular, and though many of the houses are handsomely and substantially built, a great part of the town is in a ruinous state. The principal church of Morella, built in 1317, is remarkable for its internal architecture. There are also two other churches, three convents, several schools, a town-house, a theatre, and an hospital. The manufacture of blankets and sashes, which is carried on here, gives employment to 1500 hands; and these articles, together with wheat, form the exports of the place. Morella was taken by surprise in 1838 by Cabrera, who kept possession of the town till it was retaken by Espartero in 1840. Pop. 5180.

MORELLI, GIACOMO, a celebrated librarian of Venice, was born in that city on the 14th of April 1745. He was educated by the Dominicans, and was in due time admitted to the priesthood. The subject, however, which chiefly interested him was that of bibliography, in which

he was destined to attain to great eminence and distinction. In 1774 he printed his *Dissertazione Storica della pubblica Libreria di S. Marco*. In 1785 he published his Latin version of the Oration of *Aristides against Lepidines*, the Declamation of *Libanius for Socrates*, and fragments of the second book of the *Harmonic Elements* of *Aristoxenes*, all from Greek manuscripts. One of his most important publications is that of the *Fragments* of Dion Cassius on Roman history, with new readings, which appeared in 1798, and was followed by a great variety of other works and editions. In 1802 the Emperor Francis conferred on him the title of aulic counsellor; in 1816 he received the decoration of a knight of the iron crown. He died in 1819, at the advanced age of seventy-four. A list of his dissertations on history, philology, literature, and the fine arts, will be found in the first volume of his *Opuscoli*, Venezia, 3 vols. 8vo., 1820, preceded by an interesting notice of the author by Moschini.

MORERI, LOUIS, author of the *Dictionnaire Historique* which bears his name, was born at Bargemont, in Provence, on the 25th of March 1643. He received the elements of his education at Draguignan and at Aix, and after studying theology at Lyons, where he acquired a knowledge of the Italian and Spanish languages, he took priest's orders. At the age of eighteen he composed the *Pays d'Amour*, a frigid allegory, and, under the title of the *Doux Plaisir de la Poésie*, made a collection of pieces in verse possessing but little merit. But the idea which had long occupied his mind was the composition of his Dictionary, which appeared at Lyons in 1673, in one volume folio, when he was only thirty years of age. The immense erudition displayed in this work excited general admiration; but, as might have been expected, it was found to be very incomplete. The author, however, applied himself with great vigour to enlarge it; but was cut off by death at Paris on the 10th July 1680, at the premature age of thirty-eight. The second edition, in two volumes folio, was printed at Paris in 1681, the year after his death. The third edition, which appeared in 1683, is merely a reprint of the second; but in 1689 a third or supplemental volume was published; and the whole, revised, corrected, and enlarged by Leclerc, was afterwards printed at Amsterdam, 1691, in four volumes folio. To the imperfections of this dictionary we are indebted for that of Bayle, who at first proposed only to correct the errors or supply the omissions of Moreri. The principal defect of Moreri's work consists in the inaccuracy of the geographical portion, in the awkward jumble of mythology and history, in his perplexed nomenclature, and the number and prolixity of his genealogies; but he has nevertheless the merit of being the author of the first work in which are found the names of all those personages who have any title to celebrity. Moreri was also the editor of the *Vies des Saints*, in three volumes, and of De Chinon's *Relation Nouvelle du Levant*, or treatise on the religion, government, and customs of various eastern nations. Besides collecting materials for an historical and bibliographical dictionary of celebrated Provençals, he had commenced a History of the Councils; and left in manuscript a treatise on New Year's Gifts.

MORESQUE. See ARABESQUE, and GROTESQUE.

MORETO-Y-CABANA, AUGUSTIN, a celebrated Spanish dramatist, flourished in the former half of the seventeenth century. A few isolated facts are the only record of his personal history. He shared in the patronage which Philip IV. extended to literary men, and he stood second to Calderon alone in the favour of the theatre. In wealth of fancy, fertility of invention, and rapidity of composition, he was inferior to the greatest of his contemporaries. Yet his power of depicting character was rivalled in few of the dramas of his predecessors. So strikingly life-like was his

Moreri
||
Moreto-y-Cabana.

Moreton
Bay
||
Morgagni.

picture of *The Handsome Don Diego*, that the name in a short time came to be used as a national synonyme for a fop. He also showed an infallible dexterity in constructing dramas on borrowed plots, which in course of time superseded their originals in the public favour. The best of all his plays, *Disdain met with Disdain*, was founded on the great Lope's *Miracles of Contempt*, and drove it off the stage. But he was fated to be imitated as well as to imitate. The play last mentioned was copied, though unsuccessfully, by Molière in his *Princesse d'Elide*; and it has since been translated into German, and altered to suit the German stage. Some of Moreto's dramas were religious, such as *The Most Fortunate Brothers*; and a few were heroic, such as *The Brave Justiciary of Castile*. But the greater number were comedies of familiar life, or, as they were called, "comedies of cloak and sword." A collection of Moreto's plays was published in three volumes, 1654 and 1681. Meanwhile their author, renouncing literature, had retired to a religious house at Toledo in 1657, and had died there in 1669.

MORETON BAY, a bay of Australia, on the coast of New South Wales, about 27. 15. S. Lat., and 153. E. Long., is formed by the islands Stradbroke, Moreton, and Bribie; and is about 60 miles in length, by 20 in breadth. It may be entered by two navigable channels; that to the N., between Bribie and Moreton Islands, being 8 miles wide, and that to the S., between Stradbroke and Moreton, being neither so broad nor so secure. The bay abounds in fish, and turtles and crabs are also obtained.

MORETON-HAMPSTEAD, a town of England, Devonshire, situated on a hill on the borders of Dartmoor Forest, 11 miles W.S.W. of Exeter. It has an ancient parish church, with a lofty tower; also Independent, Baptist, Methodist, and Unitarian places of worship; and several schools. Leather and ropes are manufactured here, and granite is quarried in the neighbourhood. There are near the town some Druidical remains, and the ruins of two castles. Pop. of the parish (1851), 1858.

MORETON-IN-THE-MARSH, a town of England, Gloucestershire, 28 miles E.N.E. of Gloucester. It has a parish and an Independent church, and a national school. A market formerly held here has been discontinued, but there are still two annual fairs. Pop. (1851) 1812.

MORGAGNI, GIOVANNI BATTISTA, one of the greatest physicians of the eighteenth century, was born at Forlì in Italy on the 25th February 1682. He studied medicine at Bologna, and subsequently proceeded to Venice and Padua, where he pursued his investigations both in physics and in comparative anatomy with great ardour. At the age of twenty-four he published his *Adversaria Anatomica prima*, a work of great originality; and in 1712 was appointed professor of the theory of physic at Padua. He then occupied himself with the continuation of his *Epistolæ Anatomica*, in which he described the structure of a number of organs which had been ill observed before his time; refuted the criticisms of Bianchi, who had disputed some of his views; and exposed the errors which had been committed by Manget in his *Théâtre Anatomique*. This work, which was completed and published at Padua in 1719, was applauded by the greatest anatomists of the time, amongst whom may be mentioned Ruysch, Boerhaave, Heister, Winslow, Hoffman, Mead, Senac, and Meckel. Morgagni was now promoted to the first chair at Padua, and successively admitted a member of the Royal Society of London, of the Academy of Sciences at Paris, and of the academies of Petersburg and Berlin, besides several learned Italian institutions. Morgagni continued to labour till the close of his long and honourable career, which terminated on the 6th of December 1771, at the age of nearly ninety. The knowledge of Morgagni was not confined to the medical art. His vast erudition,

Morgarten
||
Morghen.

embraced philology, criticism, history, and antiquities, as may be gathered from the following list of his works:—*Adversaria Omnia*, Padua, 1719, 4to; *Nova Institutionum Medicarum Idea*, Padua, 1712, 4to; *In Aurel. Cornelium Celsum et Quintum Serenum Samonicum Epistolæ quatuor*, Hague, 1724, 4to; *Epistolæ Anatomicae duæ*, Leyden, 1728, 4to; *Epistolæ Anatomicae xviii.*, Venice, 1749, 2 vols. 4to; *Miscellanea Opuscula*, Venice, 1763, folio; and, finally, his most celebrated work, *De Sedibus et Causis Morborum per Anatomen indagatis*, libri v., Venice, 1761, 2 vols. folio. This treatise is still a standard work of reference on pathology, and has been translated into most of the European languages. The works of Morgagni were collected and published by his disciple Antony Larber, under the title of *Opera Omnia*, Bassano 1765, 2 vols. folio; and his Life was written, first by Fabroni in the *Vite Italorum*, and next separately by Mossea, Naples, 1768, in 8vo.

MORGARTEN, a mountain slope in Switzerland, near Lake Egeri, on the borders of the cantons of Schwytz and Zug, memorable as the field of the earliest victory of the Swiss in their struggle for independence. This happened on the 15th of November 1315, when an Austrian army of 20,000 men, being entangled between the mountains and the lake, were totally defeated by 1800 Swiss mountaineers, totally unaccustomed to war. A chapel was erected on the battlefield, in which service is performed annually on the anniversary of the battle.

MORGHEN, RAFFAELLO SANZIO, *Cavaliere*, one of the most distinguished engravers of the eighteenth century, was born at Naples in 1758. His father followed the profession of engraver, and from him young Morghen received his earliest instructions; but in order more profoundly to initiate him in the art, he was afterwards placed as a pupil under the celebrated Volpato. He assisted this great master in engraving the famous pictures of Raphael in the Vatican, and the print which represents the miracle of Bolsena is inscribed with his name. He married the daughter of his master, and being invited to Florence to engrave the masterpieces of the Florentine gallery, he removed thither with his wife in 1782. All the works which he produced on this occasion were admirable; one in particular, the copy of Raphael's "Madonna della Seggiola" is considered not only as the most excellent in the collection, but as a *chef-d'œuvre* of art. His reputation now became so great as to induce the artists of Florence to recommend him to the grand duke as a fit person to engrave Lionardo da Vinci's noble composition of the "Last Supper," which adorns the wall of the refectory in the Dominican convent at Milan. This picture is not only itself dilapidated, but the drawing which was made for Morghen being unworthy of the great original, the print, although an admirable production, fails to convey a correct idea of the style and merit of Lionardo. His fame, however, soon extended over Europe; and the Institute of France, as a mark of their admiration of his talents, chose him as an Associate in 1803. In 1812 Napoleon invited Morghen to Paris, and paid him the most flattering attentions. A list of this great artist's works was published at Florence in 1810; the number comprised 200 compositions; but subsequently to this period he produced a considerable variety of admirable prints. Amongst the most remarkable of Morghen's productions, besides those already mentioned, may be noticed the "Transfiguration," from Raphael; a "Magdalen," from Murillo; a "Head of the Saviour," from Da Vinci; the "Car of Aurora," from Guido; the "Hours," from Poussin; the "Prize of Diana," from Domenichino; the "Monument of Clement XIII.," from Canova; "Theseus vanquishing the Minotaur;" portraits of Dante, Petrarca, Ariosto, Tasso, and a number of other eminent men. Morghen died in 1833, at the advanced age of seventy-five.

Morhof
||
Morland.

MORHOF, DANIEL GEORGE, a learned German philologist, was the son of a notary, and was born at Wismar, in the duchy of Mecklenburg-Schwerin, in 1639. From the academy of Stettin he removed in 1657 to the university of Rostock to study law. His attention, however, was also given to elegant literature, and his Latin and German verses introduced him to public notice. He was in consequence appointed professor of poetry at Rostock in 1660; and after visiting the universities of Holland and England, he commenced his new duties in the following year. His zeal as a teacher, his extensive scholarship, and his poetical talents, in a short time led to his further promotion. In 1665 he was chosen professor of eloquence and poetry in the newly-founded university of Kiel. This chair was exchanged in 1673 for that of history. The office of librarian to the university was added in 1680, and was peculiarly acceptable to so eager a student and so voluminous an author. Morhof fell into a dangerous malady in 1690, and died in 1691 at Lübeck, on his way back from the mineral waters of Pyrmont. Of his numerous works the only one that is still valued is his survey of universal literature, under the title of *Polyhistor Literarius, Philosophicus, et Practicus*. The best edition is that of Albert Fabricius, 2 vols. 4to, Lübeck, 1747.

MORIER, JAMES, an eminent traveller and novelist, was born in 1780. In his youth he made an extensive tour through the East, of which he published an interesting account, entitled *Travels through Persia, Armenia, and Asia Minor*. He revisited Persia in 1810 as secretary to the British ambassador; and during the six years of his residence there he became thoroughly acquainted with the character of the natives. The first and best of his eastern novels, entitled *The Adventures of Hajji Babá of Ispahan*, appeared in 1824 in three volumes. Its genuine oriental tone, and its racy and truthful descriptions, soon secured a wide popularity. The author was thus induced in 1828 to publish a continuation in two volumes, containing an account of his hero's adventures in England. Of the same stamp, and nearly as successful as *Hajji Babá*, were his two novels *Zohrab* and *Ayesha the Maid of Kars*. Morier died at Brighton in 1848.

MORLAIX, a town of France, capital of an arrondissement of the same name in the department of Finistère, is situated at the head of the joint estuary of the rivers Jarleaux and Kerlent, which here unite their waters, 34 miles N.E. of Brest. The valley in which it stands is entirely occupied by the water, with only a line of quays and a single street on each side; while the hills, covered with gardens and woods, rise steeply close behind the houses. The streets are irregular, and the houses antique and fantastic, with the upper storeys overhanging the lower. The town has a large square, surrounded by handsome buildings; and the principal edifices are two churches and a court-house. Linen, oil, and candles are the chief manufactures; and there is a national tobacco manufactory, the tobacco of which is said to be the worst in Europe. The harbour is safe, but difficult of entrance; and the trade is considerable in live stock, hides, linen, paper, corn, wine, brandy, &c. Pop. (1851) 11,698.

MORLAND, GEORGE, a famous painter, was a lineal descendant of Sir Samuel Morland, and was born in the Haymarket, London, on the 26th June 1763. Before the age of six he had taken to the pencil as if by instinct, and was producing drawings which were sold without any difficulty. His father, an ignorant man and an indifferent artist, undertook the entire superintendence of his training. He denied him every recreation, shut him up in a garret, forced him to produce sketches for sale, and incited him to progress in his studies by pampering his boyish appetites and vanities. Under such discipline the young artist simultaneously improved in painting and degenerated in morality;

so that by the time he was sixteen he was alike precocious in talent and in vice. In his seventeenth year he threw off the paternal thralldom, and rushed with eagerness into gaiety and dissipation. His facile and masterly pencil was incessantly plied to defray the expenses of the most thoughtless prodigality. Even in the very heat and excitement of conviviality, he dashed off sketches of rural economy, notable for their elegance and quiet truthfulness. His representations of pigs and asses were especially unrivalled. He might now have realized a handsome competence, and have risen into the esteem of the learned and the great. But his affections were perversely fixed, and his money was freely lavished upon such companions as prize-fighters, hostlers, and pot-boys. Even a virtuous and attractive wife, and the pleasures of a comfortable home, failed to charm him away from his haunts of gross gratification and uproarious merriment. During all this time, when his painting was supplying money for his pleasures, his pleasures were supplying subjects for his painting. He was depicting tap-rooms and hedge-alehouses with that delicate tact of genius which, in handling an object, selects all those properties that are essential and picturesque, and rejects all those that are accidental and coarse. Such pictures as these raised his fame without increasing his fortune. He was continually infested by swarms of accomplished swindlers, who decoyed him on in his giddy round of dissipation, supplied him with money to pay for his prodigality, and exacted in return sketches far exceeding in value the sums that had been advanced. In course of time Morland became a squalid debtor, skulking in obscure alleys, and straining all his cunning to escape from tipstaffs. He was arrested; but by the intercession of his friends he obtained the Rules of the Bench. There his light-headed dissipation was indulged, and his felicitous sketches were produced as incessantly as ever, until he was set free by the Insolvent Debtor's Act. By this time his constitution was irrecoverably shattered. In his thirty-ninth year he was struck with a palsy; an arrestment for debt followed, and he was lodged in a spunging-house in Eyre Street. He died there in 1804. (See Cunningham's *Lives of British Painters*, &c.)

MORLAND, Sir Samuel, a skilful mechanician, was the son of a clergyman, and was born at Sulhamstead-Bannister in Berkshire about 1625. He was educated at Winchester school and at the university of Cambridge. Several years afterwards he became assistant to Thurloe, the secretary of Cromwell. His exertions in behalf of the fund for the persecuted Piedmontese first brought him before the notice of the public. He acted as commissioner extraordinary for the distribution of the collected money; and published in 1658 the *History of the Evangelical Churches of Piedmont*. In 1659 he is said to have discovered and betrayed a plot formed by Cromwell, Thurloe, and Sir Charles Willis, for alluring Prince Charles over to England, and overthrowing the royalist cause by one blow. His services in behalf of the King were rewarded after the Restoration by several honours and dignities. He was created a knight and a baronet, was appointed master of mechanics to his Majesty, and a gentleman of the royal privy chamber, and received a pension of £400. About this time he seems to have become thoroughly engrossed with his mechanical studies. His invention of the speaking-trumpet was divulged to the world in 1671, in a treatise entitled *A Description of the Tuba Stentorophonica*. Two years afterwards he published an account of an arithmetical machine which he had invented in 1666. He also improved the fire-engine, capstan, and especially the pump and the water-engine. The cost of these inventions and improvements ruined his fortune, previously diminished by misfortune and imprudence. Blindness was added to his calamities; and he spent the last three years of his life subsisting almost entirely on the benevolence of Archbishop Tenison, and giving vent to his

Morland.

Mormon-
ism.

serious reflections in a work entitled *The Urim of Conscience*. He died about 1696. An unpublished autobiography of Sir Samuel Morland is in the library at Lambeth Palace.

MORMONISM, the name given to that system of faith maintained by the Mormons, or Mormonites, or Latter-day Saints, a religious sect which has sprung up in the United States of America during the present century, and whose progress has been attended with surprising success. Mormonism is unquestionably one of the greatest religious impostures of this or of any age; and the evidence which has been adduced of the unblushing effrontery and blasphemous lies employed to give it currency is so cogent and overwhelming, that no one but a fanatical dupe of the delusion could give credence for a moment to such a tissue of deceptions.

The author of the Mormon imposture was one Joseph Smith, who was born in the town of Sharon, Windsor county, Vermont, U.S., on the 23d December 1805. His father, who was a small farmer, removed afterwards with his family to Palmyra, New York, where they lived a sort of idle, vagrant life, and were principally known as money-diggers. The elder Smith was notorious for his incantations, delusions, and lies; and he soon discovered that his son Joseph concealed under a guise of dulness and sloth a decided genius for "second-sight." Accordingly, when a money-digging excursion was projected, young Joseph was chosen guide; and by looking through a peculiar stone, which he placed in his hat, he "saw into the depths of the earth," and decided where the money-seekers should begin to dig. Dig they did, but unfortunately always blundered in the process; so that no gold was found, and yet the correctness of Joseph's vision remained unchallenged. Despite the want of success which attended their ostensible profession of money-digging, the Smiths contrived, by whatever means, to be nearly always idle and very generally drunk. In addition to those accomplishments, they practised that of lying. A number of the most respectable residents in their neighbourhood solemnly declared upon oath that "no credit can be given to any one member of the Smith family." These general traits of the family character were all to be met with in the person of Joseph Smith junior, only in fuller development and richer growth. Indeed, these early personal vices were afterwards publicly admitted by "the Prophet," and dexterously turned to his own advantage. In short, the founder of Mormonism had, at the period of his finding the Golden Bible, a well-authenticated character for dexterous knavery, astute lying, and gross drunkenness: a very limited moral capital certainly on which to commence business as a founder of a new religion. Nor were his literary qualifications of a much higher order. He could read tolerably, write imperfectly, calculate with difficulty, and, as his inspired productions afterwards showed, blundered sadly in spelling, and held all grammar in abhorrence. Yet to a man who sees "remarkable visions," and is favoured with an occasional visit from John the Baptist, what may not be possible?

According to the testimony of Mr Peter Ingersoll, who was a neighbour of Smith's from 1822 to 1830, taken under oath in 1833, the future "Prophet" came in one day with a joyful countenance to the deponent, and communicated to him the following piece of information:—"As I was passing yesterday across the woods after a heavy shower of rain, I found in a hollow some beautiful white sand that had been washed up by the water. I took off my frock, and tied up several quarts of it, and then went home. On my entering the house I found the family at table eating dinner. They were all anxious to know the contents of my frock. At that moment I happened to think of what I had heard about a history found in Canada, called the *Golden Bible*; so I very gravely told them it was the Golden Bible. To my

Mormon-
ism.

surprise, they were credulous enough to believe what I said. Accordingly, I told them I had received a commandment to let no one see it; for, said I, no one can see it with the naked eye and live." The deponent then goes on to state:—"Notwithstanding he [Smith] told me he had no such book, and believed there never was any such; yet he told me that he actually went to Willard Chase to get him to make a chest in which he might deposit his Golden Bible." In September 1827, after this interview with Ingersoll, Smith went to Chase and asked him to make him a chest, for he expected soon to get the Golden Bible. Shortly after, Smith returned to the workman, and said that he had been directed to a hill in the neighbourhood, where he found the book deposited in the ground, and hid it in a tree-top. The elder Smith's tale of this wonderful discovery was highly embellished with the marvellous, and was at the same time perfectly characteristic. The book was marvellous; it had been found in a marvellous way; it required marvellous qualifications to obtain it; and it was marvellous to an unparalleled degree in the influence it had exerted over the faith of the family of Smith. No one had seen the book, indeed, but the inspired Joseph; but then its disclosure to the eye of mortal was prohibited by a special revelation of the book itself. The origin of the Golden Bible, however, is a genuine historical fact, and is briefly explained.

In the year 1809 one Solomon Spaulding, a graduate of Dartmouth College, and who had for some time been a clergyman, having relinquished his profession in favour of mercantile pursuits, removed first to Cherry Valley, New York, and subsequently to Conneaut in Ohio. Being a man possessed of a sort of literary taste, he occupied his leisure hours in writing a fabulous account of the origin of the North American Indians, who at that time were alleged by some to be the descendants of the lost ten tribes of Israel. He laboured for three years upon this religious fiction, which he entitled *The Manuscript Found*. Two of the leading characters in the book were Mormon and his son Moroni, who figure so largely in Joseph Smith's Book of Mormon. To give the work a fictitious origin, he resolved to bring it forward as having been found in a cave; and, to lend it an air of antiquity, he adopted the style employed in the common translation of the Scriptures. Spaulding made no secret, moreover, of the curious task on which he was engaged. On the contrary, as his work progressed, says his widow, "the neighbours would come in from time to time to hear portions read, and a great interest in the work was excited among them;" which, among other things, showed how exceedingly easily the honest folks were pleased; for in point of dreary dulness and stupidity a more notable MS. never came from the pen of man. Solomon's brother John was "perfectly familiar with the work," and afterwards recognised it at once when it had been converted into the Golden Bible. "He was amazed and afflicted that it should have been perverted to so wicked a purpose." The evidence of Spaulding's brother, and that of Lake his partner, as to the identity of the Book of Mormon and *The Manuscript Found*, was given publicly upon oath, and is thus far conclusive. (See *Exposé of Mormonism*, by John Bennett, Boston, 1842.) Spaulding completed his volume about 1813; and there appeared an announcement in the newspapers of the day that it consisted of a translation of the Book of Mormon, recently discovered, containing a history of the lost tribes. The manuscript was placed in the hands of a printer or bookseller, named Patterson, at Pittsburgh, Pennsylvania, who was much pleased with the work; but before any definite arrangements could be come to respecting its publication the author died. The manuscript remained in the possession of Patterson, who lent it to one Sydney Rigdon, a compositor in his employment, and who combined with his calling of printer the functions of preacher to some

Mormon-
ism.

sect of religionists. Whatever may have been Rigdon's ultimate design, it is at least alleged that he deliberately copied out the manuscript of Spaulding. How Joseph Smith and this person became connected is not known; but at all events, by taking advantage of the rage for religious excitement then current in various parts of the States, the idea originated between them of making a new Bible out of Solomon Spaulding's historical novel. But how was the imposture to be palmed upon the world? This required considerable address; and a consummate amount of craft and brazen-faced impudence were brought to the task. In the authorized Mormon chronology of the most important events which have transpired in their church we find the first three entries as follows:—"1820. Early in the spring, J. Smith jun. had his first vision. 1823. September 21, J. Smith jun. had a second vision, in which was revealed to him the existence of the plates from which the Book of Mormon was translated. The next day he opened the place where the plates were deposited, and saw them. 1827. September 22, J. Smith jun. obtained possession of the plates of the Book of Mormon, the Urim and Thummim, and Breastplate." Now, this is skilfully done: there is no undue haste or precipitation displayed; the mind of Joseph had to undergo a gradual preparation before he could be deemed worthy to be made the vehicle of a new revelation. The progress of events have also another aspect. Nothing could be made of Spaulding's manuscript during Patterson's life; and hence "the plates" could not be obtained possession of till 1827, a few months after the worthy printer died. All this falls in admirably, the one part with the other. The way is now clear, and Joseph's long-expected Golden Bible makes its appearance. He found it deposited in the ground, the characters beautifully engraved on plates of gold, fastened together by rings of the same metal. Joseph was a mean scholar, but he was inspired to execute the task of translating this mysterious language into English. He set to work accordingly, in conjunction with Rigdon and one Oliver Cowdery, who acted as scribe, and interpolated at judicious intervals in Spaulding's manuscript certain religious maxims, prophecies, &c., garbled from the sacred Scriptures, and engrafted upon the original romance—not itself a miracle of correctness—in a manner so illiterate and clumsy as at once to betray the ignorance of the interpolator. But all errors are admitted by the Mormons. With them no amount of anachronisms or contradictions can invalidate the plenary inspiration of the Book of Mormon. Joseph Smith was a chosen vessel, and it was not necessary that he should write correct English. The inspired translator, however, despite all his money-digging, was a poor man, and his coadjutor Rigdon, printer and preacher, was little richer. Money must be had to carry on the divine task; for Joseph was only inspired to translate Egyptian hieroglyphics, not to discover the philosopher's stone. Martin Harris, a farmer, more wealthy than wise, and a man who had already gone through all the phases of faith within his reach, was fixed upon as a fit subject on which to operate. Simple Martin proved an easy prey: the revelation which said, "impart it [*i.e.*, thy property] freely to the printing of the Book of Mormon" (sec. 44 of *Doctrines and Covenants of the Latter-day Saints*, Nauvoo, 1846) he could neglect only at his peril; and so the dollars of the honest farmer began gradually to slide through his fingers, with little immediate prospect of recovering them. His faith began to diminish as well as his purse, and something required to be done to increase it. He was accordingly despatched by Joseph Smith, with what the credulous farmer was led to believe to be a fac-simile of a portion of the golden plates, to Anthon of New York, the well-known editor of various classical works, to test the learning of the professor on the Golden Bible. The scholarship of the classic was at fault: the Book of Mormon was beyond his

comprehension. "It consisted," Anthon afterwards wrote to Mr Howe in 1834, "of all kinds of crooked characters, disposed in columns, and had evidently been prepared by some person who had before him at the time a book containing various alphabets, Greek and Hebrew letters, crosses, flourishes, &c." "I began to regard it," he says, "as part of a scheme to cheat the farmer of his money, and I communicated my suspicions to him, warning him to beware of rogues." Harris returned to "the Prophet," who doubtless turned the professor's apparent ignorance to good account. The printing of the Golden Bible commenced, and Harris was loud in his praises, to the printers, of the wonderful wisdom of the translators of the mysterious plates. The printers had their suspicions, however, and they were not to be duped. To bring this vaunted wisdom to the test, after putting one sheet in type, they laid it aside, and told Harris it was lost, and must be replaced. "After two or three weeks," says Mr Tucker, who was connected with the office, "another sheet was produced, but no more like the original than any other sheet of paper would have been, written over by a common school-boy after having read, as they did, the manuscripts preceding and succeeding the lost sheet." The Book of Mormon was ultimately published; and among other revelations of the will of God, Smith was declared to be his "Prophet," with all power, and entitled to all obedience. He soon found himself at the head of a small but rapidly-increasing body of ardent followers. The first conference of the sect as an organized church was held at Fayette on the 1st June 1830, when the numbers of the "Saints," including the family of the Smiths, amounted to thirty. During the same year a revelation was made to Joseph, styling him "Seer, Translator, Prophet, Apostle of Jesus Christ, and Elder of the Church," and enacting that "the church shall give heed to all his words and commandments which he shall give unto you; for his word shall ye receive as if from mine own mouth, in all patience and faith." (*Doc. and Cov.*, &c., sec. 46.) Joseph began boldly and openly to baptize his disciples in a neighbouring stream; but the inhabitants of Fayette knew too much of the swindling money-digger and his fraternity to tolerate such a pitch of blasphemous audacity, and accordingly employed language and threw out hints by no means flattering to "the Prophet." He judged it prudent to transplant his new religion elsewhere, and accordingly removed to Kirtland in Ohio, a revelation having been duly promulgated to that effect. This place continued to be the residence of "the Prophet," and the ecclesiastical seat of the sect, till 1838, when they migrated to Missouri. In 1831, after their removal to Kirtland, a revelation was promulgated that they should consecrate all their property to God. Joseph accordingly set up a mercantile house and a bank, appointing himself president, and Rigdon, the *fidus Achates*, cashier. This speculation had only a temporary success, however. Joseph had perhaps forgotten, or not sufficiently considered, the revelation of his earlier career—"In temporal labours thou shalt not have strength, for that is not thy calling." (*Doc. and Cov.*, sec. 9.) At all events, in 1837 the bank stopped payment, and "the Prophet" was induced to depart secretly in the night for Missouri, leaving his creditors to their own shift. He probably had a "revelation" for this movement also. Kirtland did not prove a Zion to the Mormonites: "the Prophet" was tarred and feathered by the mob; and his followers had to submit to numerous indignities at the hands of the "Gentiles." The history of the sect for the next three years after their removal to Missouri is one of strife and contention with their unrelenting enemies. Not a few of the "Saints" themselves showed signs of disaffection and declension, and a great schism broke out in 1838, when Joseph found it necessary to denounce his chosen confederates, Cowdery, Harris, and Rigdon. The Mormons presumptuously claimed the entire

Mormon-
ism.

Mormon-
ism.

country as theirs by spiritual right, and the people of the neighbouring districts, not fully appreciating the validity of the claim, and dreading the fanatical ambition of the "Saints," commenced a series of outrages upon them, which ended in sheer massacre and bloodshed, and the final expulsion of the Mormons from Missouri. It must be admitted, however, that they were most cruelly treated by the Missourians; and, considering the slight causes of aggravation, the conduct of the people of Far West was altogether reprehensible.

A few months after their compulsory departure from Missouri, the Mormons, amounting in all to 15,000, found refuge in Illinois, where they founded the city of "Nauvoo," and appointed Joseph Smith mayor. The recent reverses which the sect had undergone had tended, if possible, to exalt "the Prophet" still higher in their estimation. His unflinching courage in the most perilous circumstances commanded their admiration; and his constant reliance on the ultimate triumph of his cause inflamed their fanaticism, and inspired them with the most extravagant hopes. The organization of the sect was gradually becoming more complete, and the Mormons had already begun to display that steady industry and judicious frugality on which their subsequent success has so much depended. New converts or wandering adventurers flocked from all parts of the Union, and even from England, to cast in their lot with the followers of "the Prophet," and add a stone to the temple of the "Holy City." The darling dream of the impostor's ambition was now becoming realized. His supremacy was undivided, and his word was law. He was both temporal and spiritual head of his people, and not only enjoyed the titles of "Prophet," "President," and "Mayor," but also rejoiced in the military distinction of "General" Smith, in virtue of his command over the Nauvoo Legion, a body of militia which he had recently organized. The period of the "Saints" residence in Missouri was not at all rich in "revelations." Their hold upon the territory was too insecure to warrant any likelihood of success in the prophetic art. Joseph thought, with Epimenides and Bacon, doubtless, that in these circumstances it was safer to prophesy after the thing had happened. Affairs had now assumed a more settled aspect in Illinois; and a "revelation" was made known to the faithful of "Come ye with all your gold and silver," &c., to build a "boarding-house;" and "let it be built in my name, and let my name be named upon it, and let my servant Joseph Smith and his house have place therein from generation to generation, for ever and ever, saith the Lord." Joseph was always duly provided for in all the revelations. In this "boarding-house," it is said, the "revelator" kept a tavern, which proved a very successful speculation. But the great undertaking of Nauvoo was the building of the Mormon temple, on which it is said the sect expended nearly a million of dollars. The foundation of this splendid edifice was laid with great pomp on the 6th of April 1841. The rapid growth of the "Holy City" was quite surprising; and the spiritual pride of the "Saints" kept pace with their prosperity. In 1843 Joseph aspired to the presidency of the United States, and published a statement of his views. He did not succeed; but he soon discovered that all his presidential authority was required among his own disciples at home. Their former presumption towards the "Gentiles," and their own private dissensions, were again renewed. Sidney Rigdon, who had been re-admitted into the confidence of "the Prophet," introduced a novelty called the "spiritual wife" doctrine, which led to great scandal, and ultimately to an unexpected catastrophe. Smith, though he discountenanced the practice in public, seems to have been himself a warm patron of polygamy, and is said to have rivalled Mohammed in the number of his favourites. But Rigdon outdid "the Prophet" here, and had "revela-

Mormon-
ism.

tions" of his own, in which he blasphemously claimed the sanction of Heaven for systematic seduction. Whether justly or unjustly, Smith himself was charged by certain of his own followers with countenancing and even practising this abominable doctrine; and in attempting to extinguish this alleged scandal by violent measures, "the Prophet" brought himself within the power of the legal authorities of the county. He was imprisoned, with his brother Hyrum and certain of his confederates, in Carthage, to take their trial for riot. The governor pledged his word to protect them against threatened violence; but on the evening of the 27th of June 1844, "nearly two hundred men with blackened faces" rushed into the prison where the obnoxious sectaries lay, and instantly fired upon them. Joseph and Hyrum were both shot dead on the spot, but the rest escaped.

Thus fell this singular character, who, from a position of poverty, ignorance, and vice, had, in the short space of twenty years, raised himself, by the most unblushing imposition and blasphemous fraud, to be the acknowledged head of 100,000 ardent followers, and the author of a creed which had already found zealous teachers and ready believers over half the globe. Whether in his later years he continued the vulgar and ambitious impostor of his earlier career, it is difficult to say. There are not a few incidents in his later life which would favour the supposition that he really believed what he asserted. It would seem that, by a whole life of falsehood and deception, he had so habituated himself to assumption and imposition, that a lie became the only possible truth for him. But however this may be, he was certainly one of the most notorious men of modern times.

On the death of Smith, addresses and proclamations were issued to the "Saints;" and Brigham Young, an English Mormon, succeeded, after expelling Rigdon, in securing the leadership of the sect. After a short period of transient prosperity, new troubles and hostilities arose between the "Saints" and the "Gentiles." A battle ensued between the Mormon forces and the state militia, which ended in the final expulsion of the former from the "Holy City" and the Illinois territory. Some went to the western border of Iowa, and formed a temporary settlement on the Missouri River. A large body sought a permanent refuge in the Great Salt Lake Valley, between the Nevada and the Rocky Mountains,—“a remarkable pilgrimage,” says Dr Mackay (*The Mormons, or Latter-day Saints*, 1856), “which has not been paralleled in the history of mankind since Moses led the Israelites from Egypt.” The pioneers of this great and perilous expedition entered the Great Salt Lake Valley on the 24th July 1847. Their persecutions, which they had suffered manfully and with surprising patience, being now over, they devoted themselves to the labours of the field with extraordinary industry and success. Since the period of their arrival, a large and flourishing city, called the “Great Salt Lake City,” has arisen at the foot of the splendid mountains which surround the valley; and the long arable reaches of land in the neighbourhood are skilfully cultivated, and are yielding rich and abundant crops. A “perpetual emigration fund” was organized in 1849, to enable the poorer converts to Mormonism to reach the promised land. From all parts of Britain, and from many cities of the Continent, and especially from Germany, thousands of proselytes to the new faith are annually flocking to the land of Utah. Polygamy, which was at first concealed under the doctrine of the “spiritual wife,” is now openly practised, and even inculcated as a Christian duty, and is leading to the worst of consequences. (See *Patriarchal Order, or Plurality of Wives*, by Orson Pratt, Liverpool, 1853.) The inequality of the sexes is at once a religious doctrine and a rule of life among the “Saints.” Women must obey their husbands in all things, whether

Mormon-
ism.

right or wrong. Numerous cases of desertion are said to be daily occurring; and from an account given of the state of Mormon affairs at head-quarters, by twenty-six of their number who had escaped in June 1857 to San Francisco, it would appear that instant death is the doom of all apostates. A band of blood-thirsty ruffians, called the "Destroying Angels," has been instituted for the extermination of all deserters and apostates from the faith. So utterly are many of their deluded adherents disgusted with the bestiality practised in the Holy City, that it is confidently alleged, that if the government of the United States were to afford them protection from the persecution consequent on desertion, one-half of the inhabitants of the Great Salt Lake Valley would seek a residence elsewhere. Brigham Young, a clever, audacious blackguard, is the political as well as the spiritual head of his people; and he has recently preached open rebellion against the United States, of which Utah since 1850 has formed a territory. Such a system is a virtual treason against the laws of human society; and the government of the United States is at present (Nov. 1857) contemplating an armed expedition to Utah to reduce the "Saints" to sounder views of territorial obedience. Lieutenant Gunnison, however, affirms that, with their 8000 militia, who are under excellent discipline, the Mormons could defy the whole 10,000 of a standing army possessed by the United States. (*History of the Mormons*, by Lieutenant Gunnison, Philadelphia, 1852.)

The first Mormon mission to England was begun in 1837; and in 1843 the converts throughout different parts of Britain amounted to upwards of 10,000. They were almost entirely drawn from the illiterate among the working-classes,—Wales furnishing a larger proportion than any other part of Great Britain. From authentic returns published by an American paper in August 1856, it appears that the Mormons number in America 68,700; of whom 38,000 are in Utah, 5000 in New York, 4000 in California, 5000 in Nova Scotia and Canada, and 9000 in South America and the Sandwich Islands. Europe contains 39,000; of whom 32,000 are in Great Britain and Ireland, 5000 in Scandinavia, 1000 in Germany and Switzerland, 500 in France, and 500 in the other countries of Europe. In Asia they are said to number 1000; in Australia and Polynesia, 2400; in Africa, 100; on travel, 1800. There are in addition 8500 schismatics, including Strangites, Rigdonites, and Wightites. Their aggregate amount is above 120,000; and it is supposed that the whole sect cannot exceed 126,000. These statistics are considerably below those published by the "Saints" themselves; but it is alleged by those who have visited the Great Salt Lake, that, from some cause or other, the faithful are greatly given to exaggeration on this point. Their number, as at present estimated by themselves, is upwards of 300,000.

The precise religious creed of the Mormons cannot be easily ascertained. They profess to believe in the word of God recorded in the Bible, also in the Book of Mormon, and the Book of Doctrine and Covenants, which in their opinion completes the Scriptures, and forms the fulness of the gospel. Their mode of interpreting Scripture, however, is often somewhat peculiar. They describe God in their symbolic books as "a material, organized intelligence, possessing both body and parts." They maintain that the gift of prophecy and the power of working miracles have not ceased, and that many of their number can work miracles and cast out devils. They hold that the end of the world is near, and that they are the "saints" mentioned in the Apocalypse, who will reign with Christ in a temporal kingdom in this world. The seat of this kingdom, they allege, will be either Missouri or their present location in Utah. They hold, that in order to be saved men must comply with four conditions:—They must believe in Christ's atonement; they must repent of their sins; they must

receive baptism by immersion, administered by an apostle of Christ's appointment; they must receive the laying on of hands for the gift of the Holy Ghost, by duly authorized apostles. They recognise two orders of priesthood, called the "Aaronic" and the "Melchizedek;" and are governed by a prophet, twelve apostles, "the seventies," bishops, high-priests, deacons, elders, and teachers. (See *A Compendium of the Faith and Doctrines of the Church of Jesus Christ of Latter-day Saints*, by F. D. Richards, 1857, *passim*.)

The first cause of the rapid and vigorous growth of Mormonism which strikes the attention is the alleged possession of a living visible prophet, and a direct and permanent inspiration. Its votaries are thus saved the trouble of wrestling with those problems of life which demand solution from all earnest minds who do not pin their faith to any outward authority. They accordingly inform us in their authorized organ (*Millennial Star*, vol. xiv., p. 444), that "Latter-day Saints know that the Lord has spoken in this age; they know that angels do now converse with men; they know that the gifts of the Holy Ghost are manifested in these days by dreams, &c." In the second place, the skilful organization of the sect has enabled it to direct the energies of its votaries to the best purpose. They have made a very religion of industry. Thirdly, we may ascribe very much of the success of Mormonism to the discontent which prevails among the working-classes against the rich. To many such the voice of the Mormon apostle sounds like that of Moses to his oppressed brethren in Egypt, inviting them to fly from oppression and slavery to that promised land where the poor are lords of the soil, where social equality is the rule, and universal brotherhood the grand maxim of life. This cause has doubtless operated more extensively in making converts to Mormonism among our operatives in this country than is generally supposed. Another cause, which cannot be overlooked, is the premium held out upon sensualism by elevating some of its grossest practices into direct Christian duties. But while these causes may serve in some degree to explain the rapid extension of the Mormon delusion, have we any reason to suppose that any or all of them will be sufficient to secure its permanent stability? While any answer to such a question must be to a great extent conjectural, it is nevertheless tolerably obvious that Mormonism contains within itself more than one element of weakness and decay. The present zeal for proselytism must to some extent pass away when the necessity for increasing the population has ceased, by the requisite 60,000 elevating the present Utah territory into a state of the Union. Secondly, the rooting of the sect to a single spot will tend—if future "revelations" prevent not—by localizing it, to limit its ultimate extension, and neutralize its vaunted catholicity. Thirdly, the theocratic and democratic elements, which are at present merged together, will be in constant danger of being confounded. The death of a president may lead to a violent disruption any day. And, in the last place, it is alleged by those who have resided in Deseret that the rising generation of the "Saints" is growing up faithless and false,—the younger citizens laughing in their sleeve at the "martyr" Joseph with his plates and prophesying. If this be so, we shall have the old cycle of the world's history again repeated (*si licet parva componere magnis*), of an age of scepticism succeeding a generation of credulity,—of lazy luxury and gross sensuality following in the wake of earnest, manly industry and honourable prosperity. (Conybeare's *Essays*, p. 280.)

Mann; *The Mormons or Latter-day Saints, with Memoirs of the Life and Death of Joseph Smith, the "American Mahomet,"* London, 1852; *The Mormons, or Latter-day Saints, a Contemporary History*, by Charles Mackay, LL.D., London, 1856; Olshausen's *Geschichte der Mormonen*, Göttingen, 1856, 8vo; *A Visit to Salt Lake, being a Journey across the Plains, and a Residence in the Mormon Settlements at Utah*, by William Chandless, London, 1857.

MORNAY, PHILIPPE DE, *Seigneur du Plessis-Marly*, was born at Buhuy or Bishuy in Upper Normandy, in France, in 1549, and was educated at Paris. He made rapid progress in the belles-lettres, in the learned languages, and in theology, which was then thought a prodigy in a gentleman. He was destined for the church by his father, who was a zealous Roman Catholic; but the principles of the Reformation, which he had imbibed from his mother, effectually excluded him from the ecclesiastical preferments to which, by his interest, abilities, and birth, he would have been entitled. After the horrible massacre of St Bartholomew, he travelled Italy, Germany, England, and the Low Countries; and after his return joined the King of Navarre, at that time leader of the Protestant party, and since so well known by the name of Henri IV. This prince sent Mornay,—who employed his whole abilities, both as a soldier and a writer, in defence of the Protestant cause,—to conduct a negotiation with Elizabeth, Queen of England. He was left wholly to his own discretion in the management of that business, and was successful in almost every negotiation. He tenderly loved Henri IV., and spoke to him upon all occasions as to a friend. When he was wounded at Aumale, he wrote to him in these words:—"Sire, you have long enough acted the part of Alexander; it is now time you should act that of Cæsar. It is our duty to die for your Majesty. It is glorious for you, Sire, that I dare venture to tell you it is your duty to live for us." This faithful subject did everything in his power to raise Henri to the throne; but when he deserted the Protestant faith he reproached him in the bitterest manner, and retired from court. Yet Henri still loved him, and had occasion afterwards to give evidence of his continued attachment to this tried servant. Mornay's knowledge, probity, and valour made him the soul of the Protestant party, and procured him the contemptuous appellation of the "Pope of the Huguenots." He defended their doctrines both by speech and writing. One of his books, *Un Traité de l'Institution de l'Eucharistie*, published in 1598, having stirred up the Catholic divines, he refused to make any reply to their censures and criticisms except in a public conference. This was accordingly appointed to be held in the year 1600 at Fontainebleau, where the court then was. The two champions were Duperron, Bishop of Evreux, and Mornay. After a great many arguments and replies on both sides, the vic-

Moro
||
Morocco.

tory was adjudged to Duperron. He had boasted that he would point out to the satisfaction of every one five hundred errors in his adversary's book, and he partly kept his word. The Calvinists did not fail to claim the victory on this occasion, and they still continue to do so. But this conference, instead of putting an end to the differences, was productive of new quarrels amongst the controversialists, and of much profane wit amongst the libertines. When Louis XIII. was making preparations against the Protestants, Mornay, who was governor of Saumur, wrote him a letter, full of enlightened freedom, dissuading him from such a measure. But these remonstrances produced no other effect than the loss of the government of Saumur, of which he was deprived by Louis XIII. in 1621. He died two years afterwards, on the 11th November 1623, aged seventy-four, in his barony of La Foret-sur-Seure in Poitou.

His principal works are,—*Un Traité de l'Eucharistie*, 1604, folio; *Un Traité de la Vérité de la Religion Chrétienne*, 8vo; *La Mystère d'Iniquité*, 4to; *Un Discours sur le Droit prétendu par ceux de la Maison de Guise*, 8vo; curious and interesting *Memoirs*, from the year 1572 to 1629, 4 vols. 4to; *Letters*, written with great spirit and good sense. David des Liques published a Life of De Mornay, in a quarto volume; and additional information regarding him will be found in the *Lives of the Ancient Seigneurs of Mornay*, by R. de Mornay de la Villetertre, 1689, 4to. The greater number of his works were translated into English during his own time.

MORO, ATTONI, or SIR ANTHONY MORE, an eminent portrait-painter, was born at Utrecht in 1512, according to some, but in 1525 according to Van Mander, in his *Het Leven der Schilders*. He studied his art under Jan Schoorel; and after making a professional visit to Italy, he commenced to paint portraits in the style of Hans Holbein. His rise to eminence was rapid. In 1552 he was invited to Madrid by the Emperor Charles V. to execute a likeness of Prince Philip. Two years afterwards he was in London painting the portrait of Queen Mary. For this picture an annual salary, and, as some suppose, the honour of knighthood, were conferred upon him. He was also employed to sketch the likenesses of several of the English nobility. On the death of Mary in 1558 Moro returned to Spain, and lived there for two years in great honour with the Emperor Philip. He then repaired to the Netherlands, and was received into the service of the Duke of Alva. His death took place at Antwerp about 1581. "Moro's style," says Stanley in his *Dutch and Flemish Painters*, "so much resembles that of Holbein as to frequently create a doubt to which of them a portrait is to be attributed; but he is not so clear and delicate in his colouring (perhaps from having painted so much in Spain) as that master."

MOROCCO.

MOROCCO, or *Marocco*, an empire in the N.W. of Africa, called by the natives *Moghrib-el-Acsa*, or the Extreme West, lies between 28. and 36. N. Lat. and between 1. 20. and 11. 30. W. Long. It is bounded on the N. by the Straits of Gibraltar and the Mediterranean, E. by Algeria, S. by the Sahara, and W. by the Atlantic. Area estimated at 222,560 square miles.

Mountains. The natural features of this extensive country present mountains, plains, and valleys in the utmost variety. The country is traversed from N.E. to S.W. by the Atlas Mountains, which consist of several parallel chains rather than of a single range. The southern portion of these mountains is known by the name of the Greater, and the northern by that of the Lesser Atlas. The north-eastern extremity of

the latter approaches the Mediterranean at Cape dell' Acqua to the W. of the mouth of the Mulwia; and a branch called the Er-Riff Mountains stretches westward, and terminates at Ceuta, opposite to Gibraltar. The most celebrated of these is the craggy limestone mountain known by the modern name of Apes Hill, the *Mons Abyla* of antiquity, and one of the Pillars of Hercules. Towards the Atlantic on the S.W. the Greater Atlas consists of two ranges, one of which ends at Cape Gher and the other at Cape Nun. On the N.W. of the main ridge there is a plain stretching towards the Atlantic, and on the S.E. another stretching towards the Sahara. The whole of Morocco consists of two mountainous and two lower regions. Of the mountainous regions, the most extensive, though not the most elevated,

Morocco. is that of Er-Riff, which lies along the coast of the Mediterranean, consisting of barren, rocky heights, with narrow valleys. The other mountainous region consists of the Atlas itself, with the adjacent table-lands and inferior ridges. The mountains of this chain present in general a broad and rounded appearance; but the extreme summits are often bold, steep, and inaccessible. The highest point is believed to be Mount Hentet, which is about 13,000 feet above the sea; and Miltin, which is situated to the S. of the town of Morocco, attains the height of 11,200 feet. Of the geology of the Atlas Mountains little is known, except that the lower portions, as far up as 3000 or 4000 feet, consist of secondary limestone, and no traces of volcanic agency have been observed. The north-western plain is for the most part level, and slopes gradually towards the sea. The soil is naturally rich and fertile; and although there are in some places large forests of underwood, and tracts of undulating ground, the uniformity of the surface is in general broken by few trees or eminences. The lowlands, which lie to the S.E. of the Atlas, are of a quite different character from those of the N.W.; for the plains and valleys here are rocky and barren; but there are in many places large clumps of date palms, so that the region to which these districts belong has obtained the name of *Bilud-ul-Gerid*, or the "country of palms." The coasts of Morocco present as much variety of appearance as the surface of the interior. On the Mediterranean, along which this country extends for 230 miles, the coast is bold and rocky, corresponding to the mountainous character of the inland regions in this part. The most remarkable promontories are those of Ceuta, opposite Gibraltar in Europe, which rises to a considerable elevation; and Cape Spartel, a little further west. The same sort of coast continues beyond the Straits, as far south as the 35th degree of latitude; but about that point a remarkable change takes place. The coast here consists of low sand-hills, behind which there are two lakes, the larger being about 20 miles in length by $1\frac{1}{2}$ in breadth. Further to the south the coast is again bold and rocky; but between the extremities of the two branches of the Atlas it is generally low and sandy. The principal headlands on the Atlantic coast of Morocco are Cape Nun in the extreme S., and Cape Blanco in N. Lat. 33. 8., W. Long. 8. 40.

Rivers.

The mountain range of Atlas separates those rivers of Morocco which enter the Atlantic from those which water the south-eastern lowland, and either fall into the Mediterranean or are lost in the sands of the Sahara. The furthest north of the Atlantic rivers is that of El Khos, which rises in the mountain of Er-Riff, and has a length of about 100 miles. The Sebou rises in the Lesser Atlas, flows westward through a rich and fertile plain, and after a course of 230 miles, falls into the Atlantic. From the same mountains, and in the same direction, flows the Bu-Regreb, a small river only 100 miles in length. The Oom-er-Begh, which flows in the same direction farther to the S., is the largest of the rivers that fall into the Atlantic, being supposed to be upwards of 300 miles long. The Tensift and the Sus also fall into the Atlantic. The Draha, which rises on the E. of Mount Atlas, and was formerly supposed to lose itself in the Sahara, is now believed to fall into the Atlantic, 32 miles S.W. of Cape Nun. On the same side of the mountains rise three rivers,—the Fileli, Ziz, and Ghir, which flow southwards into the Sahara; and the Mulwia, which, rising in the south of the Lesser Atlas, flows northward into the Mediterranean, and has a length of 400 miles. The last of these forms in the lower part of its course the boundary between Morocco and Algeria, but comparatively little is known of the character of the country through which it flows.

The western part of Morocco enjoys a very temperate climate, and the heat does not vary more than from 40°

to 90° in the course of the year. This arises on the coast from the cooling sea-breezes, which blow here with great regularity; while in the interior the mountains shelter it from the hot winds of the desert. The year consists of a wet and a dry season; the former of which nearly corresponds to our winter, and continues from November till March, during which time showers frequently fall, with short intervals of dry weather. The other part of the year, on the contrary, is generally dry, showers being unfrequent. Towards the south, also, less rain falls than in the rest of Morocco. On the south-east side of the mountains it is not so well known what is the nature of the climate; but it is probably more extreme in heat and cold, especially the former, on account of its proximity to the Sahara. On this account, also, no rain falls in the south-eastern part of Morocco.

Climate.

The mineral resources contained in the Atlas Mountains are believed to be great. Of these, copper forms the principal part, and is obtained near Teseleight, on the southern slope of the mountains. Gold and silver are also found in some parts, but not in any great abundance. There are said to be iron mines in the interior; and sulphuret of antimony, which is used by the native ladies for painting their eyebrows, is obtained from Tedla. Lead, tin, and rock-salt are the chief of the other minerals of Morocco. The soil produces many useful and valuable vegetables; but agriculture is in a very backward state, so that the full advantage is not derived from the fertility of the soil and the mildness of the climate. Wheat, barley, rice, maize, and durra grow in the level regions in great abundance, and the last of these forms the chief article of food to the people. Besides these, pulse of various kinds, cotton, tobacco, hemp, saffron, and sesamum are also grown; and in the neighbourhood of the towns vines are raised, but only for the sake of their grapes and raisins. The trees of Morocco comprehend most of the fruit trees of Southern Europe, such as figs, pomegranates, lemons, oranges, &c. The forests of Er-Riff contain many kinds of oak, among which are the cork oak, and that which bears edible acorns. The north-western slopes of the Atlas are covered with forests of cedar, pine, juniper, olive, walnut, and other trees; while the only trees found on the slopes looking towards the desert are the date and dwarf palm.

Of wild animals there are in Morocco a great number, especially in the southern parts. Lions, panthers, hyenas, wild boars, gazelles, and antelopes abound, especially among the mountains; and ostriches are hunted on the southern borders of the country. Morocco is also sometimes laid waste by locusts. The domestic animals are numerous; and the inhabitants are more extensively employed in rearing cattle than in the culture of the ground. The Moorish horses were formerly highly esteemed; but the breed has now much degenerated, as the best of them are always appropriated by the Sultan, and the exportation of them is prohibited. The number of horses is estimated at 400,000. Horned cattle are more numerous, amounting to 5,000,000 or 6,000,000; and bulls are largely employed in field labour. The sheep amount in number to 45,000,000, and are highly valued on account of their wool. The goats are very numerous; and camels, mules, and asses are also reared.

The population of Morocco consists of many different races, which have never amalgamated or united, but remain quite distinct from one another. The most ancient race seems to be that of the Amazighis or Mazighis, a nation widely spread over the north of Africa, and believed to be the descendants of the ancient people mentioned by Herodotus under the name of Mazyes. Those who inhabit Morocco occupy the mountainous regions, and are divided into two tribes,—the Berbers, who live in the mountains of Er-Riff, and the Shelluhs, in the Greater Atlas. The former are middle-sized, well-proportioned, strong, and fair in com-

plexion, and live by hunting and rearing cattle. Their habitations are tents or caves in the mountains. Those on the coast are also much addicted to piracy. The Shelluhs are less robust than the Berbers, and have a sallow complexion resembling the Portuguese. They live in houses built of stone, and employ themselves in agriculture and various handicrafts. Altogether they are more civilized than the Berbers. It has been questioned whether the languages of these two tribes are distinct, or merely different dialects of the same. The latter opinion seems the more probable; and it is believed that these are dialects of one language, which is spoken throughout the north of Africa, from the Nile to the Atlantic. The level portions of Morocco are chiefly inhabited by Arabs, of which there are two races,—the Arabs proper, and the Moors. The Arabs, properly so called, are the descendants of those who settled here on the first spread of the Mohammedan religion, and they retain the manner of life of their forefathers in the deserts of Arabia. They live in tents, follow pastoral avocations, and speak a corrupted form of the language of the Koran. The Moors form the most numerous and the dominant race in Morocco. They are sprung from the Mohammedan conquerors of Spain, who were expelled from that country after the conquest of Granada in 1492. These people originally consisted of Arabs, mingled with the aboriginal Amazighis and with the Vandals. When they returned to Africa, however, after their expulsion from Spain, their kinsmen refused to have any intercourse with them, regarding them merely as foreign invaders. The Moors now inhabit the towns and villages, and the country near the coast, so that it is with them only that the Europeans have any intercourse. They are of middle size and very stout; pride and indolence are their chief characteristics; and their manners and customs resemble those of the Egyptians. They speak a dialect of the Arabic, mingled with many words from the Amazighi and Spanish languages. Among all these tribes many Jews are to be found, especially in the places of trade. They are oppressed and despised by the other races, but notwithstanding this, they frequently amass great riches. Their condition, however, is somewhat better among the Berbers than among the other tribes. There are also Negroes, who are brought as slaves from Soudan, and are very numerous in the southern districts. They are treated with considerable mildness, and frequently obtain their liberty.

Government.

The empire of Morocco is divided into four territories, which were formerly independent kingdoms, but are now subject to the sultan. These are,—Fez, occupying the northern portion, between the Oom-er-Begh and the Mediterranean; Morocco, occupying the centre, between this river and the Atlas; Suse, occupying the south; and Tafilet, occupying the country to the east of the Atlas. The subdivisions of these are not at all distinctly marked, though they were formerly believed to consist of several provinces, the names of which were derived in some cases from the natural features of the country, and in others from the tribes that inhabit it. For administrative purposes, Fez and Morocco are each divided into fifteen *ammala* or districts, while three more are made up by the other territories. These districts sometimes comprise no more than a single town, and sometimes extend over a large tract of country. Each is under the dominion of a *kaid*, who collects the taxes from his subjects. The Sultan of Morocco, over those tribes which are really subject to him, has unlimited power. He is supreme both in civil and ecclesiastical matters, and has titles which signify "Lord of the Faithful," and "Viceroy of God on earth." His power is not limited, as in Turkey, by councils or ministers, but he is himself the sole lord of the life, liberty, and property of his subjects. There is no law in Morocco but the will of the sultan and his subordinates; the inferior officers plunder

the people, and are in their turn plundered by the sultan. Wherever he happens to reside, he gives audience personally four times a week, for the administration of justice, and sentence is always pronounced without any delay. The dominion of the sultan, however, only extends over the plains; for the Amazighis, who inhabit the mountains, have never been brought into subjection to the Moors, and have a sort of republican government among themselves. The only standing army in Morocco consists of 5000 Negroes, who form the sultan's body-guard. There is also a sort of militia, who are occasionally called out, but receive no pay, except a horse, and a small present when they visit the capital. They are good horsemen and marksmen, but quite undisciplined, and therefore not very effective. The empire is hereditary, and confined to males; but it is not always the eldest son who succeeds, and the succession is frequently disturbed by bloodshed and civil war. The revenue is chiefly derived from taxes on corn and cattle, which are paid in kind, and a poll tax on the Jews; but it is very fluctuating, and has often to be raised by force of arms from the Arab tribes.

The religion of the country is for the most part Mohammedan, and the rites and ceremonies of that creed are observed with the most rigorous strictness; the Jews are everywhere despised, and the only Christian establishment in the country is a Franciscan convent at Tangiers.

The number of elementary schools is great, and in them the children, who go at the age of six, are taught reading and writing, and learn by rote passages from the Koran. There are also upper schools preparatory to entering the university, or "House of Science", as it is called, at Fez. In that institution the principal branches taught are grammar, theology, logic, rhetoric, geometry, and medicine. The art of printing is unknown; but many persons are employed in transcribing the Koran and other books; and writing is much cultivated and esteemed. Arts and sciences are in a very low state; and the only musical instruments are a rude pipe and drum. The people have, however, some taste for music, and among the Shelluhs some plaintive melodies are sung.

In the country districts of Morocco manufactures do not form a separate branch of employment, but each family is supplied with the necessaries of life by the labours of its own members. All the women are able to spin woollen and cotton thread, which is woven into cloth by the men. More extensive manufactures are carried on in the towns, and among these tanning occupies the most important place. In this art the workmen of Morocco surpass those of Europe; for they are able, by means of two plants found in the mountains, and not known to Europeans, to render the skins even of the lion and panther extremely soft and white. They have also the art of producing very brilliant colours in leather, which are believed to be inimitable in Europe. Of the fine leather known by the name of Morocco, the yellow kind comes from Morocco proper, the green from Tafilet, and the red from Fez. Fez is also remarkable for the woollen caps known by that name, which are manufactured here, and dyed of a bright-red colour by means of a berry found in the neighbourhood. Silk stuffs and girdles are also made at Fez; and the inhabitants are very skilful as goldsmiths and jewellers. In the city of Morocco silks and embroidered goods are also manufactured; and in that province, and the province of Suse, those carpets are made which are called in Europe Turkey carpets. Besides the articles already mentioned, gun-barrels, pottery, and ropes are manufactured at various places, but not to any great extent, nor of good quality.

The commerce of Morocco is carried on chiefly through three channels,—viz., 1. By sea, with Europe; 2. By means of caravans to Mecca, with the shores of the Levant; and 3. Across the Great Desert, with Soudan and the other states

Morocco. of Central Africa. The trade with Europe by sea is believed to have been begun in 1551 by an Englishman named Thomas Windham; and at the present day two-thirds of the entire trade is in the hands of Great Britain. It is carried on in the seaports along the coasts of the Mediterranean and the Atlantic. The following table shows the amount of the exports and imports of the chief ports of Morocco, from the most recent returns:—

Ports.	Exports to		Total.	Imports from		Total.
	British Ports.	Foreign Ports.		British Ports.	Foreign Ports.	
Larache, 1856.....	L.	L.	L.	L.	L.	L.
Dar-al-Baida (average of five years).....	21,736	76,361
Mogadore, 1855.....	228,112	55,965	62,174	136,496	31,223	167,719
Rabat (average of five years).....	284,077
Tangier, 1856.....	63,580	13,683	34,770	101,773	33,793	135,566
Tetuan (average of five years).....	9,000	...	77,263	19,000

The exports consist principally of wool, hides, skins, grain, pulse, wax, cattle, sheep, leather, ostrich feathers, &c.; and the principal imports are,—cotton, linen, muslin, sugar, tea, coffee, hardware, &c. The means of inland communication in Morocco are very defective, as there are no roads except in the neighbourhood of the towns, and wheeled vehicles are entirely unknown. Goods have therefore to be conveyed by means of mules, horses, and camels. Few of the rivers have any bridges, and the fords are often impassable in the rainy season. The trade with the East is carried on chiefly by means of the annual caravans, which proceed to Mecca at the time of the great festival there. They leave Fez seven months before the time of this festival, and the length of time thus spent in the journey affords ample opportunities for traffic at the various towns on the way. The principal articles exported by these caravans are,—cochineal, indigo, leather, woollen cloth, and ostrich feathers; while the imports are Persian and Indian goods, spices, &c. Another way of performing the pilgrimage to Mecca is by a coasting voyage from Tangier to Egypt, which is also favourable to commerce. From 1500 to 2000 pilgrims annually embark at Tangier for Mecca by this route. The commerce with the interior of Africa is also carried on by means of caravans, which cross the desert from Taflet to Timbuctoo. The principal articles exported are,—salt (which is obtained in the desert), woollen cloth, sashes, Turkish daggers, &c.; and they import by this channel ivory, ostrich feathers, gold-dust, indigo, and slaves. The profits of this branch of trade are enormous, being sometimes as much as ten times the capital laid out; but the cost of carriage across the desert is very great.

History.

The present empire of Morocco, along with part of Algeria, was known to the ancients under the name of *Mauretania*. The authentic history of the country begins from the time when the Romans first became acquainted with it, an event which did not take place till toward the end of the second Punic war. But though they then became acquainted with Mauretania, it was a long time before they conquered that country; and its monarchs were of considerable importance in the foreign and domestic wars of the Romans during the intermediate period. At the time of the war with Jugurtha, the throne of Mauretania was occupied by Bocchus, who, under the pretence of friendship, betrayed Jugurtha to the Romans, and in return for this treachery, was confirmed in his kingdom and received into alliance with Rome. On his death, the kingdom was divided between his two sons, Bogudes and Bocchus. In the first civil war of Rome, both these monarchs supported the party of Cæsar, who allowed them to retain their power; but in the war between Octavius and Antony, Bocchus assisted the former, and Bogudes the latter. Bocchus in consequence, usurped the whole kingdom while his

brother was absent in Spain, and retained possession of it till his death in 33 B.C., when Mauretania passed into the hands of the Romans. In the year 25 B.C. Augustus gave Mauretania to Juba II., King of Numidia, in exchange for his own country, which was then made a Roman province; and that prince seems to have raised the country to a high degree of prosperity, and to have introduced among the natives much of the civilization of Greece and Rome. In the year 40 A.D. Mauretania came for the second time under the power of the Romans, and in 42 A.D. was divided by Claudius into two provinces,—Mauretania Tingitana, nearly corresponding with Morocco; and Mauretania Cæsarienses, comprising part of the modern Algeria. Numerous Roman colonies were founded here, among which Tingis, the modern *Tangier*, was the most important, and gave its name to the western province: but the Roman power was never firmly established here; and the Moors joined with the Vandals on their invasion in 429. The power of the Vandals was destroyed by Belisarius in 534; but the Moors still continued independent, and made continual inroads on the more civilized portions of the country. In the latter part of the seventh century the Arabs first penetrated into Mauretania as far as the ocean and the Great Desert; and the natives of the country were either driven to the mountains, or joined with their invaders, and adopted their religion, language, and manners. For a long time after this conquest the country remained in a state of great confusion, and was not united under a single government. After the lapse of a century, however, Edris, a descendant of Mohammed, obtained so much influence over the Moorish tribes as to be recognised by them as sovereign of the northern part of Morocco; while the southern was still occupied by independent chiefs. This monarch was succeeded by his son of the same name, who founded the city of Fez in 807. In 1055 Abu Bekr, the chief of a sect of warlike fanatics, first assumed the title of sovereign of Morocco, and his grandson and successor founded the city of Morocco, and made it the royal residence. This dynasty, however, came to an end in 1202, when Fez and some of the other provinces asserted their independence. The Mohammedan conquerors of Spain were driven back to Morocco in 1492; and in the next century the territory was again united under a single emperor. This empire, however, which was extended, under Al Mansor, as far as the confines of Timbuctoo, fell to pieces in the beginning of the seventeenth century. Another dynasty was established in 1648 by Mulai Sherif-el-Fileli, King of Taflet, whose descendants are still the reigning family. In 1844 Abd-el-Kader, the ameer of Algiers, stirred up the Moors to a war with France, which led to the bombardment of Tangier and the occupation of Mogadore; but peace was concluded, and that town evacuated, in the same year. In more recent times the tranquillity of the empire has been disturbed, and the power of the sultan weakened, by internal disorders. The depredations of the Riff pirates have been recommenced; and Prussian and French vessels, as well as a Spanish establishment on the coast, suffered in 1855 and 1856 from their outrages. The French government, however, obtained in 1856 compensation from the sultan; which was the first instance of such redress being peaceably granted.

The population of Morocco is variously estimated, but it does not probably exceed 6,000,000.

MOROCCO (Arabic *Marakash*), the capital of the empire of that name, is situated on the northern side of a rich plain, 4 miles S. of the River Tensift, the principal mosque standing in Lat. 31. 37. 40. N., and Long. 7. 36. W. It is surrounded by a strongly-built machicolated wall of tapia-work, 30 feet high. The foundations are of strong masonry; square towers are placed at intervals of fifty paces; there are eleven strong double gates; and the whole is 6 miles in circumference. This area, however, is far from

Moron. being entirely occupied with buildings; it also comprehends large gardens and open spaces from 20 to 30 acres in extent. Of the eleven gates of the city, that called *Beb-el-Rom*, which conducts to the palace, is by far the best in point of architecture. It is a Moorish horse-shoe arch, richly sculptured in arabesque work, and is said to present a very fine appearance. The streets of Morocco are narrow and irregular, seldom wider than the lanes of European cities; and in many cases the lines of houses on either side are connected by arches with gates, possibly intended for defence in case of attack. Several open spaces, which scarcely deserve the name of squares, are used as market-places, and for other purposes. The houses, which are generally one storey high, have flat roofs and terraces, the side towards the street being plain and whitewashed. As an apology for windows, there are here and there narrow unglazed openings; but the interior disposition of the tenements is much in the Spanish style. Many of the doors are of cypress wood, and highly sculptured. The rooms, which are long and narrow, open into a court surrounded in some cases with arcades, and having a fountain in the centre. With the exception of a mat and a cushion or two, they are destitute of furniture. On the outside of the southern wall of the city, and facing the Atlas, stands the palace of the sultan. It is encircled by a wall equal in strength to that which surrounds the city, and occupies an area 1500 yards in length by 600 in breadth. The whole is portioned into squares laid out in gardens, round which are detached pavilions, forming the imperial residence. The floors of the rooms are tessellated with variously-coloured tiles, but otherwise they are quite plain, the furniture consisting only of a mat, a small carpet at one end, and some cushions. The walls are painted in the arabesque style, inscribed with numerous verses of the Koran in Arabic, and hung round with arms. Within the city there are nineteen mosques, two *emdrasas* or colleges, and one hospital. *El Koutubia*, the principal mosque, stands in an open place of 20 or 30 acres, and is conspicuous above all the others by its lofty square tower, which rises to the height of 220 feet without diminishing, and thus produces a striking and singular effect. It is divided into seven storeys, and its height is apparently about seven times its diameter. This tower resembles two others, which are believed to have been built towards the end of the twelfth century,—the *Sma Hassan* at Rabat and the *Giralda* at Seville. Next in height, and coeval in erection, although modernized and well painted, is the mosque of *Beni Yussuf*. It has a college of *talebs*—that is, seekers or students—attached to it; and a saint's tomb stands opposite its southern door, formed of three arches, and surmounted by a cupola, delicately wrought with rich Saracenic tracery. *El Moazin*, said to be the most ancient sacred edifice, is very large, and has several courts opening into each other. The Moorish horse-shoe arches intersect each other in various directions, and have a very rich effect. The mosque of *Bel Atlas*, the patron saint of Morocco, is surmounted by a cupola covered with green tiles. It contains the tomb of

the saint, and has an hospital attached to it for 1500 patients. The college and mosque, called *Emdrasa del Emshia*, stands near the south wall of the city.

Morosini.

The Great Bazaar, called *El Kaisseria*, is a long range of buildings, protected from the weather, and divided into numerous shops or stalls. The articles exposed for sale are,—silk scarfs, shawls, and handkerchiefs from Fez; clothes and carpets from *Ducaila*; cloth, linen, hardware, tea, and sugar, from London; almonds, raisins, and cosmetics, from *Suse*; corn, beans, and the like, from *Shragna*; dates from *Tafflet*; and boots, slippers, saddles, coarse pottery, mats, cord, &c., of domestic manufacture, together with embroidery in gold and silver, in which the inhabitants particularly excel. There are two or three markets, the principal of which is held near the north gate of the city, and is well supplied with home manufactures. There is another for the sale of horses, camels, mules, horned cattle, sheep, and other animals. There are several tanyards in the city, one of which is believed to employ 1500 persons.

The *Millah*, or Jewish quarter, which is situated at the S.E. corner of the city, is a walled inclosure of about $1\frac{1}{2}$ miles in circumference. It is densely peopled, but filthy in the extreme. All the Jews pay a capitation tax to the sultan, and are treated with the greatest contempt. The Jews exercise several arts and professions, and are the only goldsmiths, tinsmiths, and tailors in Morocco. The *Moor*s, however, are the shoemakers, carpenters, masons, blacksmiths, and weavers.

The city is supplied with water by several subterranean aqueducts. Some of these are 10 or 12 feet in depth, and stretch across the plain to the foot of the Atlas, but the most of them are in ruins, and consequently out of use. This is the strongest evidence which can be produced in support of the fact, that the population of this country was far greater formerly than it is at present, and also that the arts were then more cultivated than they are now. Cemetaries extend beyond the walls, both north and south; and there is one to the east of very considerable dimensions. The city was formerly surrounded with gardens and plantations extending to a great distance, but these have now for the most part disappeared. A few, however, still remain; and the sultan has three of about 15 acres in extent within the city, and two of about 20 acres each 2 miles distant from the walls. Every variety of fruit-tree enriches these gardens,—olive, orange, pomegranate, citron, mulberry, walnut, peach, apple, pear, vine, fig, date, apricot, and the like; whilst trees of beautiful texture or foliage,—the cedar, poplar, acacia, the solemn cypress, and the stately palm,—together with a profusion of flowers and flowering shrubs, form a picturesque scene, where the unchecked luxuriance and beautiful wildness of nature add a charm to the studied elegances of the more regular ornaments of art. The grounds are well supplied with water by means of the conduits already mentioned. The population is variously estimated at from 30,000 to 100,000, but it is probably about 80,000.

MORON, or **MORON DE LA FRONTERA**, a town of Spain, in the province of Seville, is situated on an irregular slope near the *Guadaira*, 32 miles S.E. of Seville. The town is irregularly built, for in some parts the streets are narrow, crooked, and lined with low buildings; and in others they are wide and straight, and the houses lofty. It contains a handsome church, several monasteries and nunneries, nine schools, three hospitals, and a town-house. The inhabitants are chiefly employed in agriculture; but there are manufactures of hats, soap, oil, earthenware, linen, &c. The chalk of *Moron* is much used for making whitewash, for which the town is famous throughout Spain. There is also

some trade carried on in wool and oil. To the east of the town stand the remains of an old Moorish castle of great strength, which was blown up by the French on their retreat in 1812. Pop. 10,192.

MOROSINI, **FRANCESCO**, Generalissimo and Doge of Venice, was born in that city, of an illustrious family, in 1618. At the age of twenty he signalized himself in an attack upon the pirates that infested the Archipelago. Then began his series of services against the Turkish fleets which raised him gradually and steadily to the highest offices. He was appointed commander of the naval force in 1651, and generalissimo not long afterwards. In this latter capacity

Morpeth
||
Morpheus.

he was sent in 1667 to defend the island of Candia against the Grand Vizier Coprogli. For twenty-eight months his skill, prudence, and valour repulsed the overwhelming hordes of the Turks, and rendered the siege renowned throughout Europe. At length, when his force had been wasted and weakened by pestilence and the repeated onslaughts of the enemy, he accepted honourable terms of capitulation. This treaty, concluded without the authority of the senate, was the cause of his arraignment on his return to Venice in 1669. His honour, however, was triumphantly vindicated; and on the renewal of the Turkish war in 1684 he was appointed generalissimo for the third time. He captured the island of Santa Maura at the end of sixteen days, and subdued the Peloponnesus after two campaigns. Landing at the Piræus, he took Athens, but not until the Parthenon had been partially destroyed by the explosion of a powder-magazine. Such signal success raised him to the highest honours in his native republic. The title of *Peloponnesiacus* was added to his name; his statue was erected in the hall of the Council of Ten; he was elected Doge in 1688; and he was welcomed to Venice in 1689 by the acclamations of the assembled populace. A decree of the Senate created him generalissimo for the fourth time. In 1693 he once more led the fleet of the republic against the Turks. The enemy retired before him; and ere he had an opportunity of winning fresh laurels, he died at Nauplia in January 1694. His remains were interred at Venice, in the church of San Stefano. The Life of Francesco Morosini was written by Graziani, in 4to, Padua, 1698; and by Arrighi, in 4to, Padua, 1749.

MORPETH, a municipal and parliamentary borough and market-town of England, county of Northumberland, on the north side of the River Wansbeck, 15 miles N. by W. of Newcastle. It is irregularly but not ill built, and is nearly surrounded by the river, which is here crossed by a handsome stone bridge of three arches, and also by a suspension-bridge. The two principal streets meet in the market-place, in the centre of the town, where there is a square tower with a clock and a chime of bells. The parish church, which stands on the side of the Wansbeck, half a mile out of the town, is a fine old building of the fourteenth century. There are also churches belonging to Presbyterians, Independents, Wesleyan Methodists, and Roman Catholics. Morpeth has a free grammar school, founded by Edward VI. in 1552, which had 80 pupils in 1853; besides national and infant schools, and two others which are supported by subscription. There is a town-hall, erected in 1714 by the Earl of Carlisle, after designs by Sir John Vanbrugh; and the county jail, a large and handsome building on the south of the river, was built in 1829, at the cost of £70,000. Near the latter building the gateway and a few other remains of the old castle of Morpeth are still to be seen. The town has a public library, a mechanics' institution, a dispensary, and a union poor-house. Tanning, iron-founding, brewing, and the manufacture of woollen stuffs are carried on here; and five annual fairs are held. Morpeth was burned by its inhabitants in 1215, in order to harass King John in his operations against the insurgent barons; and it was again injured by fire in 1689. It is remarkable as the birthplace of Turner the botanist, and of Morrison the Chinese missionary. The borough is governed by a mayor, 3 aldermen, and 12 councillors; and formerly returned 2 members to Parliament; but by the Reform Act the number has been reduced to one. Pop. (1851) of the parliamentary borough, 10,012; of the municipal, 4096.

MORPHEUS, the god of dreams, is represented as the son of Sleep. His office, as his name (a derivative of the Greek word *μωρφή*) implies, was to construct visions in the brain of the sleeper. He is painted in a reclining posture, with a crown of poppies around his head. Ovid (*Met.* xi. 635) was the first who mentioned him.

Morris
Dance.

MORRIS DANCE, a peculiar kind of dance practised in England and other European countries during the middle ages; and which, while varying considerably in the manner of its performance, was usually executed with castanets, tambours, &c., by young men in light dresses, with bells fixed to their feet, and parti-coloured ribbons or streamers tied round their arms and shoulders. The English morris-dance is generally supposed to have had its origin in the *morisco* or Moorish dance, adopted by the Spaniards from their conquerors the Moors, and which still delights the natives of the Peninsula under the title of the *fandango*. Strutt, in his *Sports and Pastimes*, &c., contends that the English morris-dance is not of Moorish origin; but Douce succeeds, in his "Dissertation on the Ancient English Morris-dance," appended to the 2d vol. of his *Illustrations of Shakspeare*, in turning the argument against Strutt, from a passage cited by the latter from the play of *Variety* (1649), in which the Spanish *morisco* is mentioned. According to Junius [Du Jon], in his *Etymologicum Anglicanum*, the Spanish *morisco* was also danced at puppet-shows by a person dressed like a Moor, with castanets, the dancers usually blackening their faces with soot to make them look like Moors. Peck, in his *Memoirs of Milton*, p. 135, supposes that the morris-dance was first brought into England during the reign of Edward III., on the return of John of Gaunt from Spain; but Douce, who is unquestionably the highest authority on the subject, thinks it much more probable that we had it "from our Gallic neighbours, or even from the Flemings." (Vol. ii., p. 439.) It is doubtful whether any vestiges of it can be traced beyond the time of Henry VII., during whose reign and that of his immediate successor, as we can gather from the accounts of the churchwardens, this pastime played a very important part in the rustic festivals of the parishes of England. In some places the May-games of Robin Hood, which were principally instituted for the encouragement of archery, were accompanied by morris-dancers, as a subordinate part of the ceremony. In like manner, other festivals had their morris—as Holy Thursday, the Whitsun-ales, the Bride-ales or Weddings, and the pageant called the Lord of Misrule. Laneham, in his *Letter from Kenilworth*, in his usual quaint fashion, speaks of "a lively moris dauns, according to the ancient manner: six dauncerz, Mawdmarion, and the fool;" and the Puritan Stubbs (*Anatomie of Abuses*, p. 107), whose "loud ravings against the fashionable excesses of his countrymen," have at once scandalized with their bitterness, and delighted with their minuteness, the antiquarian mind of Douce, gives a rough and ready picture, possibly as one-sided as it is graphic, of "those execrable pastimes" the morris-dances, and of the "terrestrial furies" who indulged in them. A similar tirade by Fetherston (*Dialogue agaynst light, lewde, and lascivious Dauncing*, 1582) is valuable from its minute description of "your morice dauncers," who, if they occasionally practised all the abuses laid to their charge by this old worthy, "of dauncing naked in nettes," and other unmentionable doings, on May-day mornings, it was little wonder that they excited the hostility of the honest Puritan. It is to be observed, however, that the charges here introduced against it are not directed against the simple ceremony of the morris-dance, but against other hilarious festivities to which it was occasionally attached. The genuine morris-dance was, in Warner's days (*Albion's England*, 1612, p. 121), celebrated about the time of Easter and before the May-games; for he tells us,—

"At Paske begun oure Morrise, and ere Penticoste oure May,
Tho' Robin Hood, liell John, Friar Tuck, and Marian deftly
play."

Douce, however, is of opinion (vol. ii., p. 445) that, when the practice of archery declined, and the May-games of Robin Hood were discontinued, the morris-dance was transferred to the celebration of Whitsuntide.

Morrison.

The oldest as well as the most curious and complete representation of an English May-game and morris-dance is given by Douce. The dresses and costumes of some of the figures are supposed to belong to the reign of Edward IV. (Steevens's *Shakspeare*, note to King Henry IV., pt. i.) Another curious print of a morris-dance, executed about 1460-70, is given by the same writer. The May-games and morris in those days consisted of Robin Hood, Little John, Friar Tuck, Maid Marian, the Queen or Lady of the May (sometimes personated by a boy in female attire), the fool, the piper, and several morris-dancers, habited in various modes, with handkerchiefs in their hands. A hobby-horse, constructed of pasteboard, and a dragon, were subsequently added. With respect to the collective number of the morris-dancers, it seems to have constantly varied. In one print they are nine; in another, eleven; in a third, twelve; and from different accounts it appears that they were not unfrequently limited to five. All that is known respecting Robin and his friend Little John will be found in Ritson's *Robin Hood*; and as for "Tuck, the merry friar, which many a sermon made," as Drayton has it (*Polyolbion*, song xxvi.), his history is very uncertain. The origin of the epithet *Tuck* may be guessed at from Chaucer's Reeve—for "tucked he was, as is a frere aboute." The Maid Marian is said to have represented Robin Hood's mistress; but there is no mention of the alleged prototype of the May Queen in any authentic record of the outlaw. There can be no doubt, however, that the Queen of the May existed long before the games of Robin Hood; and when he received a place in these merry-makings he was in all probability assigned the most honourable position of protector of the fair lady. The fool, with the exception of the bells tied to his arms and ankles, was in point of dress the same as the English domestic fool of the fifteenth century. Morris-dancers are now unknown in England. Waldron informs us that he saw in 1783, at Richmond in Surrey, a troop of morris-dancers; and Ritson alleges that during his time they were annually seen in Norfolk and Lancashire. About the beginning of the present century a company of them was seen at Usk in Monmouthshire, where they professed to have kept up the ceremony for 300 years. (In addition to the works already specified, the reader may consult Brand's *Popular Antiquities*, vol. i., and Gifford's *Ben Jonson*, vol. ii. The fullest discussion of the subject, however, is that of Douce, appended to his *Illustrations of Shakspeare*.)

MORRISON, ROBERT, D.D., the first Protestant missionary to China, was born of Scottish parents at Morpeth in January 1782. After receiving an elementary education from his maternal uncle at Newcastle, he was apprenticed at an early age to his father's trade of lastmaking. But his predilection was for the office of the ministry, and his spare hours were devoted to the eager perusal of religious books. In 1801 he began a regular course of study under a Presbyterian minister, and in 1803 he was received into the Independent theological academy at Hoxton. It was in 1804 that he was seized with the desire of proceeding on a mission to the Chinese. His services were immediately offered to the London Missionary Society, and were accepted. After attending the Mission College of Gosport, and studying the Chinese language under a native teacher, he set sail for China in January 1807. On his arrival at Canton in September of the same year, he commenced to perfect his knowledge of the language of the country with an intense application, which for some time imperilled his health. At the same time he was living in the dullest solitude, maintaining the strictest economy, and guarding with incessant circumspection against exciting the unreasonable jealousy of the natives. His domestic discomfort was relieved in 1808 by his marriage, and by his simultaneous appointment to the office of translator to the

East India Company's factory at Canton. By this time he had constructed a Chinese grammar, was compiling a Chinese dictionary, and was preparing for his great work of translating the Scriptures. He did not suffer his official duties to divert him from his studies. In 1814 his translation of the New Testament and his Chinese Grammar were printed. He then commenced to translate the Old Testament, with the assistance of Mr Milne, who had been sent out by the London Missionary Society. Separate portions of the Bible, and several small devotional treatises, were in the meantime printed, and were secretly distributed among the natives. He also published in 1817 an English treatise entitled *A View of China for Philological Purposes*. In the same year the university of Glasgow recognised his services in the cause of learning by conferring upon him the degree of D.D. He completed his translation of the Bible in the following year. His next enterprise was the establishment of an Anglo-Chinese college at Malacca, for "the reciprocal cultivation of Chinese and European literature." This institution was founded in November 1818, was furthered by liberal contributions from Great Britain, India, and America, and was opened in 1820. In 1821 the Chinese Dictionary was published by the East India Company at an expense of £15,000. Dr Morrison, worn out by long and continued mental exertion, now proposed to visit his native country for the sake of his health. He accordingly left China at the close of 1823, and arrived in London in the following March. He was greeted by the respect and esteem of all classes. George IV. honoured him with an interview; the Royal Society elected him one of their number; and wherever he went to advocate the cause of the Chinese mission he was received by large and enthusiastic audiences. After spending two years in attempting to interest his countrymen in the project to which he had devoted his life, he returned to China in 1826. He now set himself to promote education, to write a commentary on the Scriptures in Chinese, and to superintend the distribution of books and tracts. These labours were beginning to yield some visible fruit, when they were brought to a close by his death, at Canton, on the 1st August 1834. His remains were interred at Macao.

His *Memoirs*, compiled by his widow, were published in 2 vols. 8vo, London, 1839.

MORS, an island of Denmark, in the province of Jutland, the largest of those in the Lymfiord, being 24 miles long by 11 broad, and 283 feet above the sea in the centre; area 120 square miles. It is for the most part fertile, except in some sandy and rocky parts where the ground is covered with heath, and in some marshy places. There are, however, very few trees. The capital is Nykjöbing, with about 1000 inhabitants, and the population of the island is 13,500.

MORSHANSK, a town of European Russia, capital of a district in the government of Tambov, is situated on the right bank of the Tsna, 805 miles S.E. of St Petersburg, 358 S.E. of Moscow, and 58 N. of Tambov. It has manufactories of linen, sail-cloth, tallow, vitriol, and paper; besides a ropework, and fulling and saw-mills. An active trade is carried on in grain, honey, and live stock. Pop. (1851) 10,638. The district has a fertile soil, rich pastures, and is well wooded.

MORTAGNE, a town of France, capital of an arrondissement of the same name in the department of Orne, is situated on the summit and sides of a hill, 20 miles E. by N. of Alençon. It is well built, with a square in the centre; the principal buildings being the church, court-house, and prison. Linen, pottery, and leather are manufactured; and a considerable trade is carried on in linen, hemp, grain, and live stock. Mortagne was formerly the capital of Perche, and, from its strong position, a place of some importance. Pop. (1851) 4848.

MORTALITY, HUMAN.¹

Mortality,
Bills of.

WE shall consider this very important, as well as curious subject, under two distinct heads; the first of which will treat of the History and Formation of Bills of Mortality; the second, of the Law of Mortality.

I. MORTALITY, BILLS OF.

Bills of Mortality are abstracts from parish registers, showing, as their name imports, the numbers that have died in any parish or place during certain periods of time, as in each week, month, or year; and are accordingly denominated weekly, monthly, or yearly bills. They also include the numbers of the baptisms during the same periods, and generally those of the marriages.

Objects of
this article.

The objects of the present article are these:—First, to give a brief history of the principal things that have been done in this way, which may suffice for such as are not disposed to go further into the subject, and may at the same time indicate the best sources of information.

As both mortuary registers and enumerations of the people are much more valuable when combined than when separate, we shall also notice some of the principal enumerations, the results of which have been published. We shall then point out some of the principal defects in most of the published registers and enumerations; and, lastly, shall submit some forms for registers which will be easily convertible to useful purposes.

History.

The ancients do not appear to have kept any exact mortuary registers, at least no account of any registers of that kind, with the ages of the deceased, have come down to us; and although in the Roman *census*, first established by Servius Tullius, both the ages and sexes of the people were distinguished, we have no exact account of these particulars. Indeed the principal object of the *census* among that warlike people, was the levying of men and money for the purposes of conquest; the duration of human life appears to have occupied very little of their attention, and their proficiency in the science of quantity was not sufficient either to show them the necessary *data*, or to enable them to draw just inferences from them. A good account of what the ancient Romans did in this way, with references to the original authorities, may be found in the Italian translation of M. Demoivre's *Treatise of Annuities on Lives*, by Gaëta and Fontana, Milan, 1776. (*Discorso Preliminare*, parte 2.)

The keeping of parish registers commenced in England in 1538, in consequence of an injunction issued by Thomas Cromwell, who, after the abolition of the Pope's authority in this kingdom, in the reign of Henry VIII., had been appointed the king's vicegerent in ecclesiastical affairs. Some parish registers in Germany appear to have commenced with the sixteenth century; and in the *Göttliche Ordnung* of Süssmilch (t. iii., s. 23), we are informed, that at the time of Lord Cromwell's injunction, they had already old registers of that kind both at Augsburg and Breslau. However, the extracts there given from the Augsburg registers do not go back further than the year 1501, nor those for Breslau beyond 1555. About the beginning of the seventeenth century, such registers appear to have been established in most parts of Europe; but it was not until the year 1662 that they began to attract public notice, and to be considered as the sources of valuable and interesting in-

Mr Graunt. formation. In that year John Graunt, a citizen of London

(afterwards an officer in the trained bands of the city, and a fellow of the Royal Society), published his *Natural and Political Observations on the Bills of Mortality*, principally those for London. The London bills, or accounts of baptisms and burials, appear to have been occasioned by the plague, and to have been begun in the year 1592, a time of great mortality. They were afterwards discontinued, but were resumed in 1603, after the great plague of that year. They have ever since been continued weekly, and an annual bill also has been regularly published. In 1629, the number of deaths by the different diseases and casualties, were first inserted in them, also the distinction of the sexes; and these have been continued ever since. But it is in the totals only of the baptisms and burials that the sexes are distinguished in these bills. They do not shew how many of each sex died of each disease, neither have they, since 1728, when the distinction of the ages of the dead was first introduced, shewn how many of each sex died in each interval of age, but only the total number of both sexes.

This book of Graunt's, although the first, is also one of the best that have been published on the subject. It contains many judicious observations on the imperfections of the bills, on the proportions of the deaths from different diseases and casualties, and on their increase and decrease, with the probable causes of such fluctuations. He also observed, that "the more sickly the years are, the less fecund or fruitful of children also they be."

Besides the London bills, he gave one for a country parish in Hampshire, in the first edition of his book; and, in an appendix to the later editions, two others, one for Tiverton, the other for Cranbrook in Kent, with a few observations on foreign bills. He almost always reasons justly from his *data*; but, as these were very imperfect, in his endeavours to draw more information from them than they could supply, he has sometimes fallen into error.

Even in this enlightened age, when a much greater proportion of the people devote a portion of their leisure to the acquisition of knowledge than in Graunt's time, subjects of this kind have but few attractions for the generality even of reading men, who cannot endure the fatigue of thinking closely for any length of time. The author, accordingly, expected his readers to be rather select than numerous, and was ambitious of that distinction, as appears by the motto he prefixed to his work,

—Non, me ut miretur turba, laboro,
Contentus paucis lectoribus.

The book was, however, favourably received by the public, and went through five editions in fifteen years, the two first in 4to, the three others in 8vo; the last of them, published in 1676, two years after the author's death, was edited by his friend Sir William Petty, who, in consequence of having sometimes spoken of this edition as his own, has by some writers been erroneously considered as the author.

Graunt's observations, like all others of a similar kind, by shewing the usefulness of parish registers and bills of mortality, contributed to form a taste for these inquiries amongst thinking men; and, consequently, to improve both the registers and the bills derived from them; so that, from his time, the subject has been continually cultivated more and more. Parish registers, in most parts of Europe, have been kept with more care; and a succession of works of considerable merit have been published on the subject, containing an

Mortality,
Bills of.

¹ The present article on HUMAN MORTALITY, written for a previous edition of this work by the late Joshua Milne, has been allowed to stand in the present edition, from a regard to the high authority of the writer on the subject, and from the acknowledged excellence of the article itself. The principle, moreover, which is followed in the article, of giving the relative proportion of mortality to the actual population, renders the following discussion of the subject as valuable still as when it was written. The more recent statistics on mortality are given in an Appendix.

Mortality, important part of the natural and political history of our species, and affording valuable materials for the science of political economy.

The principal of these works we shall proceed to give a short account of, in the order of their publication.

As the ages at which the deaths took place were not inserted in the London bills till 1728, Captain Graunt could not avail himself of that important information, but made a fruitless attempt to determine the law of mortality without it.

Dr. Halley. The Breslau bills appear to have been the first wherein the ages at which the deaths took place were inserted, and the most important information which bills of mortality can afford was first drawn from them by Dr. Halley; who, in 1692, constructed a table of mortality for Breslau from these bills for the five preceding years, and inserted a paper on the subject in the *Philosophical Transactions*, (No. 196.)

Dr. Davenant and Gregory King. In 1699, Dr. Davenant, in *An Essay upon the probable Methods of making a People Gainers in the Ballance of Trade*, published some extracts from *Natural and Political Observations and Conclusions upon the State and Condition of England*, by permission of their author, Mr. Gregory King, Lancaster herald, who had completed them in 1696,

though they still remained in manuscript; and the whole of this very curious production was published by Mr. Chalmers at the end of his *Estimate* in 1802. Mr. King derived his information from the poll-books; from actual observations in particular places; from the assessments on marriages, births, and burials; and from the parish registers. Many of his conclusions agree surprisingly well, considering the time he wrote, with those which are the results of a hundred years of further observations and inquiries. He had access to much better data than Graunt, and his conclusions are more accurate; but he does not explain so fully how he arrived at them.

M. Kersseboom. From the publication of Davenant's essay, above mentioned, nearly forty years had elapsed without any thing further being done in this way, when M. Kersseboom published an essay, in the Dutch language, on the probable number of people in Holland and West Friesland, which he deduced from the Bills of Mortality, Hague, 1738, 4to; and two others in 1740 and 1742. (See LAW OF HUMAN MORTALITY.)

J. P. Süssmilch. In 1742 was published the first edition of the celebrated work, entitled *Die Göttliche Ordnung in den Veränderungen des menschlichen Geschlechts aus der Geburt, dem Tode und der Fortpflanzung desselben erwiesen von Johann Peter Süssmilch*. The second edition appeared in 1761, enriched with the materials which had been laid before the public through various channels in the interim; the third in 1765, and in 1775 a fourth edition of the two volumes of

J. Baumann. Süssmilch was published by Christian Jacob Baumann, to which this editor himself added, in 1776, a third volume, consisting of additions to the other two, and remarks upon them, with many new tables, and a copious index. The last edition of this work was published in 1798, but it does not appear to have been augmented or improved since 1776. It contains long dissertations on every thing not mathematical connected with the subject, and, besides original information, includes the substance of all the other publications on it previous to 1776; with an immense collection of materials, which, when borrowed, are often better arranged and rendered more convenient for reference, than they will be found to be in the works they were extracted from; besides, the original sources of information are always referred to, and these advantages, with that of a full index, render it a valuable work for occasional reference. The three thick octavo volumes contain upwards of two thousand three hundred pages, closely printed with a small type, and the tables alone occupy three hundred and thirty pages.

M. Deparcieux. In 1746 was published the *Essai* of M. Deparcieux, which has been already mentioned in the historical introduction to

the article ANNUITIES. Information much wanted on this subject, was there given in a very clear and popular manner, and the work no doubt contributed greatly to the advancement of the science. It probably had some influence in promoting the establishment of what is called the *Tabell-värket* in Sweden, which took place in 1749, and of which we shall have occasion to take further notice presently.

In 1750 appeared, in octavo, *New Observations natural, moral, civil, political, and medical, on City, Town, and Country Bills of Mortality; to which are added, large and clear Abstracts of the best Authors who have written on that subject; with an Appendix of the Weather and Meteors*, by Thomas Short, M.D. which he had "had on the anvil" for eighteen years, as he informs us in the preface to his *History of Air, Weather, &c.* This author, with incredible labour collected extracts from the mortuary and baptismal registers in a great many market-towns and country parishes in England, chiefly in the northern counties, in almost every variety of soil and situation, and reduced them into tables in various ways, so as to enable him to draw useful inferences from them.

He informs us that Lord Cromwell's injunction in 1538 was but little regarded in many places till the year 1559, when another was issued for the same purpose by Queen Elizabeth; nevertheless, he had procured several exact country registers, commencing with 1538, and continued without one chasm, for more than two hundred years; and the registers before 1644, he considered to be much more valuable than afterwards, on account of the increase of dissenters from that time. He likewise procured both the numbers of families and of souls in seven of the market towns, and fifty-four of the country parishes, for which he had registers; and thus arrived at satisfactory information on several points, which, till then, had been very imperfectly understood. But the sexes were not distinguished in his enumerations; neither were the ages, in any of the enumerations or registers he has given accounts of, except in the London Bills of Mortality, and what he has taken from Dr. Halley, respecting those for Breslau.

Although Dr. Short took so much trouble in collecting materials, and has generally reasoned well upon them, he has shown but little skill, and does not appear to have taken much pains in communicating his information to his readers; so that it costs them considerable labour to find what they want, especially in his tables; and when found, to understand it.

In 1751 was first printed a tract by Corbyn Morris, entitled, *Observations on the past growth and present state of the City of London*, with the most convenient and instructive tables of the London bills that have been printed; they contained the annual baptisms and burials from the year 1603, the number of annual deaths by each disease from 1675, and of each age from 1728; all brought down to the year 1750. This tract was reprinted in 1758, with a continuation of the tables to the end of 1757; these also contain useful annual averages and proportions. Mr. Morris's observations are generally very judicious, but he was one of those authors who appear to have laboured under much misconception with regard to the evils to be apprehended from the mortality of London, and what they considered to be its baneful effects in drawing recruits from the country. These writers did not perceive, or did not sufficiently consider, that the natural procreative power is much more than adequate to supply any waste of that kind, and that the real obstacle to the increase of the people, is the limited means of subsistence. This had been observed by Dr. Halley in his *Further Considerations on the Breslau Bills of Mortality*, (*Phil. Trans.* 1693,) though it there also appears, that he had not sufficiently considered the mode of its operation: this was first fully illustrated by Dr. Franklin in his excellent *Observations on the Increase of Mankind, Peop-*

Mortality, *ling of Countries, &c.* written in Philadelphia in 1751, the same year in which Mr. Morris's pamphlet was first published. The author also pointed out in that pamphlet, material defects in the Bills of Mortality, and proposed a better method of keeping them, not only in London, but throughout the kingdom. This gave occasion to a paper by Mr.

Mr. Dodson James Dodson, which was inserted in the *Philosophical Transactions* for that year (1751,) wherein he showed the importance of their being so kept as to afford the means of valuing annuities on lives, and proposed other alterations which appeared to him calculated to fit them for the purpose.

Nicolaas Nicolaas Struyck of Amsterdam, who, in his *Introduction to General Geography*, published there in 1740, had inserted (*Gissingen over den staat van 't Menschelyk Geslacht*;) *Conjectures on the State of the Human Species*; published at the same place in 1753, a quarto volume, the first half of which is astronomical, the other (216 pages) is entitled (*Nader Ontdekkingen noopens den staat van het Menschelyk Geslacht*;) *Further Discoveries concerning the State of the Human Species*. It contains statements of actual enumerations of the people in many Dutch villages, principally in North Holland, wherein the sexes are distinguished, and the numbers in childhood, celibacy, marriage, and widowhood; but with respect to their ages, it is only stated for each sex, how many were under ten years, and how many of the unmarried were above that age; except in two instances, wherein the number of each sex is given in each interval of five years of age, from birth to the extremity of life: they amount altogether to 2728, of whom not one was above the age of eighty-five, and only four above eighty.

He generally gives, for each place, the names and professions or occupations of the persons who made the enumeration, and the precise day on which it was made; or if it occupied the parties more days than one, those on which it was commenced and completed are given; a practice which shows a laudable solicitude about particulars, and a title to our confidence, the want of which we have great cause to lament in too many other writers.

Extracts from many parish registers are also given; in these, too, the ages are seldom noticed; but in a few cases they are given very minutely, especially in that of Westzaandam, for which, the numbers who died in each interval of five years of age, from birth to the extremity of life, are given; also the number in each year of age under fifteen, the number in each month of the first year of age, even the number that died in the first hour from birth, in the first twenty-four hours, and in each day of the first week of their age. During a term of nineteen years, the whole number of deaths thus registered was 3328; but the sexes were not distinguished under fifteen years of age, which Struyck himself lamented. The work also contains much information respecting the population and parish registers of *Amsterdam, Haarlem, &c.* with some accounts of other countries, and of other works on the subject.

Dr. Birch. In 1759 was published at London, in 4to, *A Collection of the yearly Bills of Mortality, from 1657 to 1758 inclusive, together with several other Bills of an earlier date*; to which were subjoined Captain Graunt's *Observations*; *Another Essay in Political Arithmetic*, by Sir William Petty; the *Observations of Corbyn Morris, Esq.*; and *A Comparative View of the Diseases and Ages, with a Table of the Probabilities of Life for the last thirty years*, by J. P. Esq. F. R. S. This is a valuable compilation, and has been generally attributed to Dr. Birch, the Secretary and Historian of the Royal Society; the preface is very judicious, and contains a good deal of information. For the following history of this publication, the author of the present article is indebted to the kindness of Dr. Heberden:—

"The bills were collected into a volume by his father, the late Dr. Heberden. He procured, likewise, observations from several of his friends, rectors of some large parishes, or

others likely to give him information; particularly from Mortality, Bishop Moss, Bishop Green, Bishop Squire, and Dr. Birch. Bills of. These, together with some of his own remarks, were thrown into the form of a preface; and the whole was committed to the care of Dr. Birch. To make the calculations which appear at the end of the book, Dr. Heberden employed James Postlethwayt, Esq. a very distinguished arithmetician."

In the year 1766, this branch of knowledge was enriched M. Me with new materials, of more value than all that had previously been laid before the public. These were contained in three publications, of which we shall first notice the *Recherches sur la Population des généralités d'Auvergne, de Lyon, de Rouen, et de quelques Provinces et Villes du Royaume*. Par M. Messance, Receveur des Tailles de l'Election de Saint Etienne.

Most of the political writers in France, for some years previous to the date of this publication, had asserted confidently that the kingdom was depopulated, but without producing any proofs. The object of M. Messance was, to enable his readers to judge of the merit of such assertions, and to pronounce less vaguely on a subject in itself so interesting, the knowledge of which can only be obtained by a great number of facts and actual observations. The work, accordingly, is filled with tables, exhibiting the results of actual enumerations of the people, and of extracts from the parish registers. They show, for each sex, how many were under fourteen, or in celibacy above that age; those in the states of marriage and of widowhood; and the number of domestic servants. The numbers of families are also stated; and the enumerations of the ecclesiastics, properly classed, are given separately; but no other information respecting the ages of the living is given than that mentioned above. A great many statements are also inserted of the numbers that died in different parishes and more extensive districts, under five years of age, between five and ten, and in each interval of ten years, from thence to the age of one hundred; during different periods of from ten to forty years or more, generally ending about the year 1760; but in these the sexes are not distinguished.

In all cases, he has given the general results of his tables, and the proportions they afford, very distinctly stated; and among these results, the increase of the population during the preceding sixty years, to which his researches were generally limited, is clearly ascertained.

The work also contains many interesting tables, in which the rate of mortality and the produce of manufacturing labour, are compared with the contemporaneous prices of grain, in various places, generally for periods of twenty years each.

In the same year was published, at Yverdon, in octavo, the work entitled *Mémoire sur l'Etat de la Population, dans le Pays de Vaud, qui a obtenu la prix proposé par la Société Economique de Berne*. Par M. Muret, premier Pasteur à Vevey, et Secrétaire de la Société Economique de Vevey. M. Muret.

The Pays de Vaud contains 112 parishes, and the population at that time was about 113,000 souls. M. Muret wrote for information to all the clergymen in the country, who made him returns of the numbers of baptisms and burials in their respective parishes, for different periods, from ten to forty years, in many of which both the ages and sexes were distinguished; and from about two-thirds of them he obtained also the numbers of marriages and families actually subsisting; also the number of souls, "or at least of communicants," in their parishes: but neither the ages nor sexes were distinguished in any of the enumerations of the living.

This performance does much credit both to the author's industry and judgment, but it has also material defects. He gave upwards of fifty tables, by which he intended to show the probabilities and expectations of life till five years of age, and at every fifth year after that, in different parishes

Mortality,
Bills of.

and places, under various circumstances of soil and situation, and for people of different habits and occupations; also for the two sexes separately. These must have cost him a good deal of labour, and would have been extremely valuable had they been correct; but, unfortunately, he did not understand the construction of such tables, and they are not to be depended upon. He also took considerable pains to determine the rates of mortality among married and single women, considered separately, and thought he had proved that it was less among the married; but the proofs he adduced were not conclusive. Some of his observations on the state of the population, and the plans he recommended for encreasing it, also show, that he did not understand the principle on which its progress depends.

It is with much reluctance that we make, on so respectable an author, remarks which apply equally to almost all his predecessors in these inquiries; but this we consider to be rendered necessary, by the *Memoir* generally, and the Tables in particular, having been praised for their extreme accuracy, in a very good abridgment of them, inserted in the second volume of a book, entitled *De Re Rustica*, or the Repository, Lond. 1770, 8vo.

The disadvantages of her soil and climate necessarily keep Sweden thinly peopled in comparison with the countries which, in these respects, are more happily circumstanced; and since the year 1748, the state of the population has been an object of anxious solicitude with the government; which, in 1749, established what, in this country, would probably be called a Board of Population, but is there denominated *Tabell-Värket*, that is, *Table-Establishment*, for reducing into convenient forms the extracts from the parish registers, and the returns from the magistrates of the numbers of the people, which the governors of the different provinces are required to state to the commissioners appointed for these purposes. The extracts from the registers are made and transmitted annually, but the enumerations only once in three years.

Printed forms, with proper blanks, distinguishing the ages and sexes, both of the living and the dead, with the diseases the deaths were occasioned by, are distributed throughout the country, to enable the people to make these returns correctly and uniformly; and the information thus acquired, respecting the state of population and mortality, is much more correct and satisfactory than what has been obtained in any other place of considerable extent; but from causes which we have not room to explain here, the results were not laid before the public until some years after the returns were made.

M. Wargentin.

M. Wargentin who was one of the Royal Commissioners of the *Tabell-Värket*, inserted in the Transactions of the Royal Academy of Sciences at Stockholm for the years 1754 and 1755, six papers on the usefulness of annual registers of births and deaths in a country; which, like all his other productions, were written with much judgment and modesty; but, to illustrate the subject, he was generally under the necessity of borrowing materials from the writings of others; as, at that time, he was only in possession of the results of complete Swedish returns for the years 1749 and 1750. In the same Transactions for the year 1766, he inserted a paper on the mortality in Sweden, in which he gave Tables exhibiting the number of the Living of each sex in each of the following intervals of age:—between birth and one year completed, between one and three, between three and five, and then in each consecutive period of five years of age till ninety, the last including all those above ninety years of age; at the three enumerations of

Mortality,
Bills of.

the people which were made in the years 1757, 1760, and 1763; with the annual average number of still-born children and of those born alive, also the number of deaths that took place in each of those intervals of age, during each of the periods of three years, which ended at the times of these three enumerations, the sexes being always distinguished. These particulars he gave both for all Sweden and Finland, and for Stockholm separately; with other interesting results of the registers and enumerations, and many judicious observations on them. The ages of the living at the different enumerations, and those at which the deaths took place in all the subsequent publications of them, have been given for the intervals of age stated above.

This paper of M. Wargentin is more valuable than all that had previously been published on the subject; it is also to be found in the French abridgment of the Stockholm Transactions, in the eleventh volume of the *Collection Académique (partie étrangère)*, which abridgment was also published separately in 4to at Paris, in 1772.

Condorcet in his *Eloge* of M. Wargentin states, that he had collected the results of his labours as Commissioner of the *Tabell-Verket* in a great work which he had not time to publish; but in that statement, there is probably some mistake. In the Stockholm Transactions for the first quarter of the year 1801, M. Nicander informs us, that M. Wargentin at his death, left in manuscript a continuation of the observations published in 1766, consisting of four statements similar to those just mentioned; the first for the years 1765, 1766, and 1767, the second for the two following years, the third for the year 1772 alone, and the fourth for 1774, 1775, and 1776; and having taken the mean of all the seven, he sent it a little before his death to Dr. Price, who published it in the fourth edition of his "*Observations on Reversionary Payments*," which appeared in 1783, the same year in which Wargentin died.

In 1767, Dr. Short published, in quarto, *A Comparative History of the Increase and Decrease of Mankind*, in which the tables are printed more intelligibly, and there is more information respecting foreign Bills of Mortality, than in his *New Observations*.

The first edition of Dr. Price's *Observations on Reversionary Payments* appeared in 1771, and contained "Observations on the expectations of lives, the increase of mankind, the number of inhabitants in London, and the influence of great towns on health and population," which had been published in the *Philosophical Transactions* for 1769, and added considerably to the information on those subjects which had been previously before the public; also observations on the proper methods of constructing tables of mortality.

In the *Philosophical Transactions* for the years 1774 and 1775, were inserted two excellent papers by Dr. Haygarth and Dr. Percival, in which he gave the Bills of Mortality for that city, for the years 1772 and 1773 respectively, in a form calculated to exhibit, at one view, the most useful and interesting information such bills can afford without calculation, and presenting to the calculator data that are essential to the solution of the most important questions respecting the state of the population. Three papers by Dr. Percival (also of considerable merit) appeared in the same Transactions about this time, relating principally to the population of Manchester and its neighbourhood.

The second part of Dr. Mochsen's "Collection of Observations for the better illustration of the great usefulness and value of Inoculation for the Small-pox,"¹ was published in 1775; in which he gave a good historical account of

¹ *Sammlung merkwürdiger Erfahrungen die den Werth und grossen Nutzen der Pocken-inoculation. Erstes Stück, Lubeck 1774; Zweites und Drittes Stück, Berlin und Leipzig 1775.* The third part, however, appears never to have been published, though stated in the title, and no doubt intended to accompany the second. Indeed at the end of the second part he gave notice that his remarks on his third table would be continued, and explanations of the remaining ones would be given, in the following part; which, however, is wanting.

Mortality, the first institution of Registers of Births, Marriages, and Deaths, and of their gradual progress and useful applications down to his time; also twenty-six tables derived from the Berlin Bills of Mortality for a period of seventeen years, commencing with 1758, and ending with 1774.

For each of the seventeen years he gave in the text what he called a Year Table, shewing for that year the number of deaths by small-pox, which took place during each month, in each of the first five years of age separately, and also in each interval of five years of age above that, with the number during the whole year in each of those intervals of age, the total number in each month of the year and also in the whole year; so far without distinction of sex or condition. But he added in each of those tables, the distribution of the number who died in the year by the small-pox into the civil and military population, shewing for each of these classes how many of each sex were children and how many adults, taking the age of fifteen years as the limit between them, without noticing the month or the interval of age in which the deaths took place. And in an 18th table he gave the same information for the first half of the year 1775. At page 152, he gave a table shewing the number of deaths in Berlin during each of those seventeen years, from all causes without distinction, but distinguishing the civil from the military population, and the sexes in each case. Amongst these deaths the still-born are included, which it is important to notice here, as he did not mention it. At the end he gave seven other which he called Principal Tables; the three first are summaries of his Year Tables; the first exhibiting at one view the number of deaths by small-pox in each month of each of the seventeen years, also those in each month during the whole term, with the whole number during each year, and the total during the whole term of seventeen years, without distinction of age, sex, or condition. The second shews the number of those deaths in each year, and the sum of them in all the years, distinguishing the sexes, the civil from the military population, and children from adults. The third shews the number of those deaths in each interval of age that took place in each year, and also during the whole term, without noticing the particulars given in the two first tables. In the fourth table he gave the numbers of male and female children separately which were born in each month of each of the seventeen years, with the total number in each year, and the total number born in each month during the whole term of seventeen years, but without mentioning whether the still-born were included in these statements or not; it seems probable that they were, as he included them in the deaths.

Taking the numbers of births and deaths, as stated by Dr. Moehsen, without attending to the still-born, it appears that

	Males.	Females.	Both sexes.
The whole number born during the seventeen years was	33,915	31,718	65,633
While there died of the civil population.....	30,473	30,153	60,626
Of the military.....	11,166	9,341	20,507
Total.....	41,639	39,494	81,133
Exceeding the births by.....	7724	7776	15,500

His fifth table shews how many children were still-born, and how many died during each of those seventeen years, also during the whole term, by each of thirteen different diseases which are the most prevalent amongst "children and others," but without distinction of age, sex, or condition, and without including the small-pox, respecting which the same information was given both in his first and third tables; that makes fourteen, of which he has given this information. But two of them, *Rittlen* and *Masern*, appear

to be only different forms or varieties of what we denominate measles, whilst of some other heads or denominations in the Berlin bills, probably each included several distinct diseases; as *disease of the chest* and *consumption*, both distinguished from *phthisis* (*Swindsucht*) which is given separately. But these Dr. Moehsen could only give as he found them in the Weekly Bills of Mortality, from which he states that he formed his Tables.

His sixth table shews the number of suicides that took place in each month of those seventeen years, and also during the whole term, in the five different divisions following, viz., by shooting, hanging, cutting the throat, drowning, and otherwise; also the number of deaths by accidents in forty-nine different ways, the whole number being 447; distinguishing the civil from the military population, males from females, and children from adults, but without stating the months in which the deaths took place. Amongst those causes of death, except drowning and sudden death, the numbers by which were ninety and one hundred and thirty-one respectively, the greatest number, thirty-nine, was of those who died by hunger and misery in the year 1772. Always excluding the still-born; the number of deaths in 1772 was 8314, whilst the annual average number of the remaining sixteen years was only 4339; so that in 1772 the mortality was nearly twice as great as on the average of the other sixteen years of the term, which shews how small a number of deaths is imputed in the bills to hunger and destitution in comparison with those which, although ascribed to other causes, were hastened and chiefly produced by want and misery.

The seventh table shews for the year 1774 alone, the number of the still-born, the number of deaths by unknown diseases, and the number of them produced by each of seventy-three different diseases and casualties according to the Berlin Weekly Bills, which took place in each month of that year and during the whole year, with distinction of the civil from the military population, males from females, and children from adults. The whole number of deaths, including the still-born in that year, was 4401; still-born 259, deaths by unknown diseases 276.

Dr. Moehsen states that the diseases were first introduced into the Bills of Mortality at Berlin in the year 1721. The sexton of every parish had some years before been ordered to leave at the senate-house, at the end of every week, a list of the names of all who had been baptized, married, or buried during that week; and in the case of the buried, the age at which, and the disease by which, each death took place, were also to be stated. But these orders were not properly attended to until 1733; from that year he made and preserved abridged extracts from them until 1753, when these were destroyed by fire. In 1757, he resumed his labours which we have here given an account of, more minute than in most other cases, but not more so than their value appears to entitle them to, whether for their useful applications or as examples worthy of being followed.

In 1778 was published at Paris, in octavo, the work entitled *Recherches et Considérations sur la Population de la France*, par M. Moheau. This book is agreeably written, in a way entirely popular, and will probably be perused with more pleasure by the generality of readers than most others on the subject of population. It contains a great number of tables, for many of which he was indebted to other writers, especially to M. Messance; but he has also given many that are original, derived from the Bills of Mortality and actual enumerations of the people, though without explaining in a satisfactory manner how he obtained his information, which, if it be correct, must have cost great labour. In his préface he says, "il est tel page de ce livre qui a coûté nécessairement deux mois de travail, et un volume de chiffres."

Mortality, Bills of.

Mortality,
Bills of.
M. Krafft.

The fourth edition of Dr. Price's *Observations on Reversionary Payments* appeared in 1783, and contained much new and valuable information on these subjects, as has already been stated above, and in the historical introduction to the article ANNUITIES.

In 1786 was published, at Petersburg, in the *Acts of the Academy of Sciences* there, for the year 1782, an essay by M. Krafft, on the marriages, births, and burials, at St. Petersburg, during a period of seventeen years, from 1764 to 1780, preceded by a general exposition of the uses such tables might be applied to, if the observations they record were extended over entire governments in Russia. This paper contains seventeen tables, which shew the number of deaths at each age, and by each of the principal diseases, together with the numbers of marriages and baptisms; the numbers in each case, being given for each of the seventeen years separately, as well as for the whole term; and the sexes are always distinguished; as are likewise foreigners from the native Russians.

These tables would have been rendered very valuable, had they been accompanied by statements of the numbers of the living of each sex in the different intervals of age; but for want of this information, it is difficult to apply them to any useful purpose, and many of the inferences M. Krafft has drawn from them are very uncertain.

Dr. Heysham.

During a period of nine years, commencing with 1779, and ending with 1787, Dr. Heysham of Carlisle kept accurate registers of the births, and of the deaths at all ages, in the two parishes which comprehend that city and its environs; also the diseases or casualties which the deaths at each age were occasioned by; and the sexes were in all cases distinguished. These excellent registers were kept with great care and skill on the plan of Dr. Haygarth above mentioned, and included all dissenters within the two parishes. Dr. Heysham published them from year to year as they were made, and accompanied them with valuable observations on the state of the weather and diseases in each year. Their value was greatly enhanced by two enumerations of the people within the two parishes, one made in January 1780, the other in December 1787, in both of which the ages were distinguished, but not the sexes of each age, though the totals of each sex were. These documents, printed in convenient forms, with further information respecting them, and many useful tables deduced from them, may be found in Mr. Milne's *Treatise on Annuities*.

Mr. Barton

In the third volume of the *Transactions of the American Philosophical Society*, published in 1793, were inserted *Observations on the probabilities of the duration of human life, and on the progress of population in the United States of America*, contained in a letter from Mr. Barton, which had been read to the Society in March 1791; also a postscript to that letter, read in December following; the returns of an actual enumeration of the people of the United States having been made in the meantime. The information there given from the parish registers is of little value. In the enumerations the sexes were distinguished but not the ages, except the numbers of free white males under and above sixteen; but even that information with regard to the population of America is very interesting, whether we contrast the early with the more recently settled counties, or the whole of the United States with the population of Europe.

M. Nicander.

M. Wargentin having died in 1783, M. Henrich Nicander was in the following year appointed his successor as astronomer and secretary of the Royal Academy of Sciences at Stockholm; and in 1791 as one of the royal commissioners of the Tabell-Verket, and their secretary. After the death of M. Wargentin, and perhaps for some time before, owing to his infirmities, the Tabell-Verket would appear not to have been duly attended to; no communications of the results having been made to the public for fifteen years

after his decease. But other new commissioners were appointed at the same time as M. Nicander, and he commenced the performance of the duties of his office by forming a catalogue of the acts and tables in the archives of the commissioners, when he found so many deficiencies in the returns from different parts of the kingdom, and so little assistance was afforded him, that it was not until the year 1799 that he was enabled to commence the publication of the most important results for the term of twenty-three years ended with 1795, and he continued to insert papers on that subject in the same transactions for the remainder of his life; he died in 1815. The following statement will facilitate reference to those papers, eighteen in number.

In the vol. for the year.	No. of papers	Stating the results of observations made during the term of	
1799	2	23 years.	1773—1795.
1800	4		
1801	2		
1805	3	8 ...	1796—1803.
1809	3	5 ...	1801—1805.
1813	2	5 ...	1806—1810.
1814	2	2 ...	1811 and 1812.

The most valuable information contained in these papers is the mean number of persons living of each sex, in each interval of age during a certain number of years, and the annual average number of deaths of persons of each sex in the same intervals of age which took place during the same time; as these data are sufficient for determining the law of mortality for each sex separately, and also for the whole population without distinction of sex. That information M. Nicander has given for all Sweden and Finland in his first paper in the transactions for 1801, both for the whole period of twenty years, 1776—1795, and for each of the four consecutive periods of five years contained in the same term; also derived from these, the proportion of the annual average number of deaths to the mean number of the living of each sex in each interval of age. And in the volume for 1809, (tab. B,) he gave the same information as to the population and mortality during the term of five years ending with 1805. In the volume for 1813, he gave the number of deaths of persons of each sex, which took place in each interval of age during every one of the five years, 1806—1810; also the number of living persons of each sex in each interval of age at the end of the year 1810. In the volume for 1814, he gave the number of deaths of persons of each sex in each interval of age which took place in each of the two years 1811 and 1812. And in all cases the numbers born alive and still-born of each sex were also given separately, but the still-born were never included among the deaths.

Sweden having lost Finland by the war with Russia in 1808, the observations recorded by M. Nicander in the volumes of the *Stockholm Transactions* for 1813 and 1814, were made in Sweden alone. The operations of the Tabell-Verket never extended to Swedish Pomerania, the Isle of Rugen, or the town of Wismar.

In the sixth and last paper of M. Wargentin, in the *Stockholm Transactions* for 1755, he gave a table shewing the proportion of the whole number of deaths produced by each of about thirty of the principal diseases; in all Sweden, in Stockholm alone, within the London bills of mortality, and in Berlin. But at that time complete returns from the whole of Sweden had only been received for the two years 1749 and 1750; and from Stockholm for the five years 1749—1753. Forty-six years from that time had elapsed without any thing further having been published on the mortality from different diseases in Sweden, when M.

Mortality,
Bills of.

Mortality,
Bills of.

Nicander resumed it in his second paper in the *Stockholm Transactions* for 1801, where, in table T, he gave for each of the twenty-one years 1775–1795, the number of deaths produced by each of thirty-seven different diseases, besides these four other causes, child-bearing, the infirmities of age, unknown diseases, accidents and other violent deaths; with the annual average number by each cause, and the proportionate number produced by each cause, out of a total number of 10,000 deaths.

In table U he gave for each diocese in the kingdom, for Stockholm and for Carlsrona, each separately, also for the whole of the kingdom, the annual average number of deaths during the same period of twenty-one years, produced by each of the causes above mentioned, without distinction of the sexes, except for the whole kingdom taken together; for which the average was given from each cause for males and females separately, and also for the whole population, without distinction of sex. M. Nicander continued his papers on the mortality produced by different diseases in Sweden, in the same *Transactions* for the years 1805, 1809, 1813, and 1814, which appears in the tabular statement of his papers given above, for the term of years there set against their respective dates of publication. But in these four papers, the mortality produced by several kindred diseases taken together was given, without distinguishing that which was produced by each disease separately. In his paper published in 1809, besides the number of deaths produced in each of the five years 1801–1805, by each disease or class of diseases, the annual average number produced by each, in every month during the same term, was given, so as to shew the effects of the seasons in increasing or diminishing the mortality from each.

M. Nicander's papers contain much valuable information which, not coming within the scope of this article, it may suffice merely to mention here. Besides the statements above mentioned, of the births and deaths in the whole of the kingdom taken together, the numbers of them which took place in the city of Stockholm, and in each of the *läns* or governments the country is divided into, are given separately for the period between each two consecutive enumerations of the people, with the excess or defect of the births in each case, as compared with the deaths; and the difference is compared with the increase or decrease of the population in the same period, determined by actual enumerations at its extremities. The number of marriages contracted, and the number dissolved by death during given periods, are also stated; with the number of pregnant women delivered in each interval of five years of age, from fifteen to fifty, and those above fifty; the number of those women who were married, and who were single; the numbers of double, triple, and quadruple births, distinguishing those born alive from the still-born, the legitimate from the illegitimate, and males from females. In the enumerations, the number of married persons of each sex, the numbers of widowers and widows, and the numbers unmarried above fifteen years of age, of each sex; also the number of children of each sex under that age, were given.

The numbers of the people, classed according to their ranks, conditions, and employments, were stated, with distinction of the sexes, and the number of children vaccinated in each year, from 1804. In the volume for 1813, the number of families in each of the four following classes was given:—1. the opulent; 2. other persons of property; 3. those subsisting by their labour; 4. the destitute poor; which consisted of two persons, from two to five, from five to ten, from ten to fifteen, and of more than fifteen persons; with the whole number of families of each of those five magnitudes, and also the whole number of families of each class or condition. In addition to these, tables were given for 1802, and the subsequent years, shewing how many Swedish tons were sown of each kind of grain, also of pease, and of

potatoes put into the ground, with the produce derived from each; the quantity of live stock of each kind; and the quantity of land under cultivation for each government of the kingdom separately.

Mortality,
Bills of.

Some of the most valuable parts of these papers of M. Nicander, with deductions from them, will be found under the second section of this article.

After the death of M. Nicander, which took place in 1815, no reports on the state of the population and mortality were inserted in the *Stockholm Transactions*, where they had always appeared previously; and as books, or any information concerning them, can hardly ever be obtained from Sweden through the London booksellers, it was not till the summer of 1836 that the author of this article learnt from Professor Nilsson of Lund, who was then in London, in what way they had been published; and to that gentleman and Mr. Charles Tottie, consul-general in London for Sweden and Norway, he is indebted for a manuscript copy of the 1st, 2d, and 3d tables, at the end of this article, which give the most important information on the subject; their authenticity he considers to be sufficiently guaranteed, by his having received them through Mr. Tottie, from M. John Ad. Leyonmarck, the successor of M. Nicander, as the secretary to the Tabell-Verket, or Registry Commission; also by comparing them with the printed tables under mentioned.

The principal printed documents on the progress of population in Sweden, since the death of M. Nicander, which the author has yet succeeded in obtaining are the following:—

1. An oblong folio pamphlet, consisting of forty leaves, (each twenty-one inches by eighteen), and containing forty-two lithograph tables, most of the pages being very much crowded with small figures, shewing all the particulars above stated with respect to M. Nicander's tables, not only for the whole of Sweden, but also for the city of Stockholm, and each of the *läns* or governments separately, which the kingdom is divided into, for the five years 1821–1825. The number in each of the usual divisions of age, at the enumeration of 1825, is given, with distinction of the sexes, and of the country people from those residing in towns. The following were the numbers for the whole of the kingdom:—

	Males.	Females.	Both sexes.
Country people,.....	1,202,989	1,287,984	2,490,973
Inhabitants of towns,	129,981	150,298	280,279
Total,.....	1,332,970	1,438,282	2,771,252

The numbers of the people in that year, classified according to rank or condition, profession or occupation, are also given. And the number of deaths in each of the five years (1821–1825) by childbirth, also those of each sex separately, by eleven different diseases, including the principal of those prevailing among children, and those by seven different kinds of violent deaths or casualties, are stated for the city of Stockholm, and each *län* in the kingdom separately.

For that city, and each of those *läns* separately, the numbers of the people in 1805 and 1810, without distinction of age or sex; and the numbers in 1815, 1820, and 1825, both with and without that distinction are given; with the numbers of births and deaths during the two quinquennial periods 1816–1820, and 1821–1825. The divisions are indeed much more minute than these; the population of the city of Stockholm is given for nine different districts separately, and the births and deaths for twenty; this arises from the population being divided into those districts for the purposes of taxation, and the twenty others are the different congregations or places of worship, where the registers of births, deaths, and marriages, are kept. But every *län* in the kingdom being divided into several districts, and each district into its separate parishes; the particulars above mentioned, are

Mortality, given for each parish separately, and also the sum of those Bills of. in each district, which shows the same things for it.

This is a very imperfect statement of the contents of these valuable tables, but sufficient it is hoped, to show those who take interest in such subjects, that they are worth being consulted and studied. The title is as follows: *The humble Report of the Royal Registry Commissioners to his Royal Majesty, on the Proportions of the Births and Deaths during the years 1821-1825, to the Population of the Kingdom in the last mentioned year; also on the observed Increase of the population of the Kingdom, during the last elapsed compared with the next preceding Decennium. Dated the 10th of May 1828.* Printed by the gracious command of his Royal Majesty.¹

2. A quarto of sixty pages, with the same title, containing an abstract of the above, printed with types in the usual way, and observations and remarks which were absent from the larger tables. In it, the results of the observations made in that quinquennium (1821-1825) are compared with those of the preceding, by placing the corresponding numbers on the same line; those of the next preceding quinquennium (1816-1820) on the left; and those of the present (1821-1825) on the right of the page, with the explanation of their import between them.

These contain almost all the more important information in the larger tables, at least to persons residing out of Sweden, and are much more convenient to use. But this is defective in giving only the numbers of violent or sudden deaths, and those without distinction of sex, with hardly any information as to the numbers by different diseases, except stating in what parts of the country they produced the greatest mortality in different years.

3. A similar quarto of seventy-four pages for the quinquennium 1826-1830, with a similar title, was in 1833, handsomely printed with much larger and more beautiful types, especially the figures, which is important. The contents of the tables in possession of the Commissioners, twenty-five in number, are here stated, and then very satisfactory extracts from them are given. The number of deaths from childbirth and twelve different diseases are given; for the preceding quinquennium, the annual averages only; but for this, 1826-1830, they are stated for each year separately; but the annual average only for violent deaths, casualties, and unknown causes. As each of these gives the results of the preceding quinquennium, the two together give them for fifteen years, 1816-1830; and M. Nicander's papers in the *Stockholm Transactions*, gave the observations to the end of 1812; those for the years 1811 and 1812 being contained in the volume for 1814. So that only the observations for the three years, 1813, 1814, and 1815, are wanting to complete the series; and the most important parts of these and others are contained in the tables above mentioned, which are given at the end of this article. Whether two other quartos similar to those above mentioned, were published, with the observations made in the two preceding quinquenniums, 1811-1815, and 1816-1820, the author had not been able to ascertain when this article was printing, (in February 1837;) nor whether any other large folio tables, similar to those above mentioned, have been published; but it is probable there have not; for in the German translation of the second edition of *Forsell's Statistics of Sweden*, by the Rev. A. G. F. Freese, preacher to the royal court of Sweden, and rector of the German National Lyceum at Stockholm, (8vo, Lubeck 1835,) it is stated in a note at page sixty-seven, on entering upon the subject of the Swedish tables, that they are often quoted by foreign authors, and

that the very large and instructive tables published in 1829, deserve much attention. There can be no doubt that these were the tables ordered by the king to be printed in 1828; although they might not have been published before 1829. Had there been any others of the kind, those probably would not have been so noticed, and as the translator must have had the best information on the subject, the obvious inference is, that no others existed in 1835.

4. A folio pamphlet of three sheets extracted from the Tabell-Verket, showing the number of persons carried off by epidemic cholera in Sweden in the year 1834.² It contains five tables, but we shall only notice the first and most important of them here; it shows the number of deaths which were produced by that disease in the year 1834,—in every län in the kingdom, and in every town and every sub-deanery in each län, in each of the usual intervals of age till twenty-five, those between twenty-five and fifty, and the number above fifty years of age; also the number in each month, without distinction of age. The estimated number of the people in each place at the commencement of that year, and the proportion of them who died of the disease are also given, the sexes being distinguished throughout. This appears to be the first publication of the number of deaths in Sweden classed according to the ages of the deceased, as well as, and together with, the causes of death. For their assistance in procuring the last mentioned and other valuable books from Sweden, the author makes his grateful acknowledgments to Mr. George Warde Norman, and Mr. H. James Prescott; also to Mr. Norman, for a manuscript table showing the number of children of each sex born alive, and the number of the still-born, without distinction of sex; with the number of deaths of persons of each sex, which took place in each of the intervals of age there mentioned, in every one of the ten years 1824-1833, in the kingdom of Norway, the authenticity of which, that gentleman has no doubt of, and therefore, neither has the author of this. In the fourth table at the end of this article, the total of those numbers for the whole term of ten years are given.

It is gratifying to see this table from Norway, so similar to the excellent form of the Swedish. In every point in which they differ, the Swedish is entitled to preference; especially in the smaller intervals of age, in which the numbers of children are given in the Swedish; and it is to be regretted, that in giving the numbers of the still-born, the sexes were not kept distinct; as the great excess of still-born males above still-born females, is an interesting subject of inquiry. It is much to be desired that these should be continued in Norway, and that periodical enumerations of the people on the Swedish plan should also be made regularly. But the author has not yet succeeded in his endeavours to ascertain whether those have been made, or are intended or not.

In the year 1800 was published, at Paris, in octavo, under the title of *Essai de Statistique*, a memoir by J. A. Mourgue, on the births, marriages, and deaths, that took place in Montpellier during a period of twenty-one years, ending with 1792, with the ages at which the deaths happened, the sexes are also distinguished, and the population of the place appears to have been nearly stationary. The tables and observations of M. Mourgue appear to be more valuable than any others relative to the population of France, that had previously been published, except those of M. Deparcieux, which related only to select orders of the people. This memoir was read at a meeting of the French National Institute in 1795, and printed in the *Mém. des Sav. Etr. an. 14.*

Mortality,
Bills of.

An enumeration of the people in Spain was made by royal authority in the years 1768 and 1769, and again in 1787; a minute account of this last was printed at Madrid, showing for each province separately, the numbers of parishes, cities, towns, villages, &c. &c. with the number of people in each class according to their ranks, professions, occupations, &c. and the monastic orders of both sexes were particularly distinguished: to these was prefixed a summary of the census of 1768 and 1769. In these two enumerations, the ages of the people were not distinguished with sufficient minuteness; they only showed how many were under seven, between seven and sixteen, sixteen and twenty-five, twenty-five and forty, forty and fifty, and above fifty. In both enumerations, together with the ages, the distinction of the sexes was given; in the first, the married were only distinguished from the single; but that of 1787 showed how many of each sex, and in each interval of age, were in the states of celibacy, marriage, and widowhood.

A third enumeration of the people in Spain and the Spanish possessions in Europe and Africa, including the Canary Islands, was made in 1797; and a full account of it, occupying nearly fifty large tables, was printed at Madrid in 1801. The distinction of the ages in this enumeration was still not sufficiently minute; under forty it was the same as in the two preceding; but after that age, the number of the living in each interval of ten years to one hundred was given, and the number above one hundred.

No information from the parish registers in Spain was given in any of these cases; although satisfactory extracts from them all, distinguishing the ages and sexes of the deceased, or even from those only which could be most depended upon, during the ten years that intervened between the two last enumerations, would have rendered the results of these incomparably more valuable, provided that the population of the places for which correct registers were given, could be distinguished from the rest. Those to whom the superintendence of these measures were entrusted in Spain, seem to have been well aware of this, and to have actually entered upon the formation of these necessary supplements to the enumerations, as appears by the following passage extracted from the introduction to the printed statement of the last census:

"Interin que se forman las tablas necrológicas, las de nacidos y casados, en que entiende el ministerio de Estado, y que son muy utiles para valuar casi geométricamente el total de la poblacion del Reyno, debemos contentarnos con las noticias que nos proporcionen los censos executados por el método que el presente." But these tables of births, deaths, and marriages, have not yet (in the year 1836,) been published, neither does it appear probable that they were ever formed.

In 1801 were published, in quarto, *Observations on the Increase and decrease of Different Diseases, and particularly of the Plague*, by William Heberden, junior, M.D. F.R.S., containing some tables, chiefly deduced from the London bills. In the advertisement prefixed to this valuable tract, we are informed that it had been intended to be subjoined to a new edition of the Bills of Mortality; which edition, however, was not published. We are also indebted to the same ingenious physician for other interesting observations on the mortality in London, inserted in the *Philosophical Transactions of the Royal Society* (for 1796,) and in those of the *London College of Physicians*, vol. iv.

In the same year (1801) was published another valuable work, entitled, *Reports on the Diseases in London, particu-*

larly during the years 1796, 1797, 1798, 1799, and 1800, in 12mo, by Robert Willan, M.D. F.A.S. part of which had been previously inserted in some periodical publications. The author's observations were made both on the Bills of Mortality, and on the cases that occurred in his own practice.

Mortality,
Bills of.

Dr. Bateman commenced a series of similar observations and reports on the diseases of London with September 1804, which he continued till the end of August 1816. The subjects of those reports were, the cases that occurred at the Public Dispensary in London, in which he was a physician; they were first published quarterly in the *Edinburgh Medical and Physical Journal*, but the author collected them into a separate octavo volume, which he published in 1819, with an introduction, in which he gave a Historical Survey of the Diseases of London.

All of the three works last mentioned, are very interesting and instructive; but it would not be consistent with the objects of this article, to notice them further here.

By art. 1, sect. 2, of the constitution of the United States of America, it was provided that the representatives and direct taxes should be apportioned amongst the several states which should be included within the union according to their respective numbers. The first actual enumeration to be made within three years after the first meeting of the Congress of the states, and within every subsequent term of ten years, in such manner as they should by law direct.¹ In consequence of this, five enumerations of the inhabitants of the United States have been made, viz. in 1790, 1800, 1810, 1820, and 1830; statements of the first four are given in the American Almanac for 1832, and of the last in the same Almanac for 1833. In the first, as was stated above, no attention was paid to the ages, except the distinction of the numbers of free white males under and above sixteen years of age. In the enumerations of 1800, 1810, and 1820, the numbers of free white persons of each sex in five different intervals of age were ascertained; but three of the intervals were much too long to admit of the enumerations being available for determining the law of mortality; the first of those long intervals being all under ten years of age; the second, those between twenty-six and forty-five years; and the third, all above that age. Of these three enumerations, it was in that of 1820 only, that the free coloured persons and the slaves were classified according to their ages and sexes; and the intervals of age into which they were distributed, were longer than those for the free whites.

In 1830, the numbers of free white persons of each sex, in thirteen different intervals of age were determined; the four divisions under twenty years of age being of five years each; the eight between twenty and a hundred, of ten years each; and the thirteenth division included those of a hundred years of age, and upwards. The numbers of each sex, of free coloured persons, and of slaves separately of each sex, in each of the following divisions of age, were ascertained. Between 0 and 10, 10 and 24, 24 and 36, 36 and 55, 55 and 100, and above 100. These particulars were given for each state and territory separately, and also the totals for the whole of the United States. Statements of all the five enumerations from that of 1790 to that of 1830, both inclusive, may be seen in the American Almanac for the year 1832. That of 1830, with the ages of the living for each state and territory will be found in the same Almanac for 1833. No general returns of the numbers of births, marriages, and deaths, appear to have been required or made throughout the United States; and previous to the

¹ Dr. Seybert, in his *Statistical Annals of the United States of America*, published in 1818, (p. 17) makes the following statement: "The United States of America alone require an actual enumeration of the inhabitants to be made at regular intervals; as far as our knowledge extends, no other instance can be furnished from the history of mankind; our practice is worthy of being followed by other nations." And a statement to the same effect is made in the American Almanac for the year 1832, (p. 156) by which it would appear, that the writers were not aware of Sweden having set a still better example of that kind more than thirty years before.

Mortality,
Bills of.

year 1820, but few births were registered there. Many marriages were till then, and probably still are, contracted before magistrates, whose records of them were seldom preserved.¹

In the city and liberties of Philadelphia more attention appears to have been paid to these subjects than in almost any other part of the United States. In the first number of the *American Journal of the Medical Sciences*, published at Philadelphia in November 1827, in octavo, there is an excellent article (the 8th), entitled, *Medical Statistics: being a series of Tables, showing the Mortality in Philadelphia, and its immediate causes, during a period of twenty years, by Gouverneur Emerson, M.D.* Dr. Emerson states, that the subject of the diseases and mortality of Philadelphia, was first made one of regular record in the year 1807, through the influence and exertions of Professor James, and that "their authenticity may be regarded as resting on very solid grounds." From authority vested in the Board of "Health, this municipal power makes it obligatory upon physicians to give certificates designating the name, age, and sex, of all who die under their care; and sextons are bound by still heavier penalties, not to permit the interment of any dead body, until such certificate is obtained, which he returns to the health office on the last day of every week, for publication. The accuracy with which the diseases are designated in these certificates, rests chiefly upon the general intelligence of the medical profession in that city, the members of which are very much in the practice of testing their pathological opinions by autopsical examinations. For the purpose of ascertaining the number born, the various practitioners of midwifery are required to render an account at the health office of all births. With regard, however, to this department, there is some reason to suspect a deficiency in the returns, especially from the outskirts of the city and liberties. But the registry of the dead has, for the most part, been kept with a care and fidelity creditable to those who have had its superintendence."

Dr. Emerson after making some general observations on the topography and climate of Philadelphia, proceeds with his observations on the eleven valuable tables which are inserted at the end of the article.

The *first* shows the results for each calendar month of thermometrical observations made at Philadelphia, during the term of ten years, which commenced with March 1811, and ended with February 1820. The *second* is an abstract of the census of the city and county of Philadelphia, taken by order of the general government in 1820.

All the observations on the Mortality were made within the period of twenty years, which commenced with 1807 and ended with 1826; the still-born being always, as they should be, given separately, and not included amongst the deaths; except in Table IV., which shows the number of deaths in each month of each of the twenty years; the Board of Health having found it impracticable to make an accurate monthly estimate of them for deduction.

In the number stated in the Philadelphia bills to be still-born, the abortions are included. The fifth and eleventh of these tables are the most valuable. In the fifth are stated the numbers of deaths from the principal diseases during the whole period of twenty years in the following intervals of age, viz. between birth and one year completed, between

one and two years, between two and five, between five and ten; then in each interval of ten years of age to a hundred and twenty; fifty-five deaths having happened between the ages of a hundred and a hundred and ten, and six between a hundred and ten and a hundred and twenty. After the columns set apart for those fifteen different intervals of age, in a sixteenth the number of deaths produced by each disease at ages not ascertained, is given; and in the seventeenth and last column, the total number of deaths produced by each of those diseases. The total number of diseases in the table is sixty-six, and the number of causes of death, old age being included, is sixty-seven.

A few cases of deaths occasioned by accidents and diseases of vague character, Dr. Emerson omitted, as tending rather to perplex than to elucidate the subject; and adopted the alphabetical arrangement in this table, as the most convenient.

The total number of deaths registered during the term of twenty years was 53,004, whilst the number included in this fifth table was 50,614; so that 2390 were excluded for the reason just stated.

Dr. Emerson's other tables and his observations on the whole of them, will be found well worth the attention of those who take interest in the subject.

In *Hazard's Register of Pennsylvania* for July 30, 1831, (No. 5, vol. viij.) there is an elaborate paper entitled, *Comparative Views of the population of the city and county of Philadelphia, from the time of the first census in 1790, till that of the last in 1830*; in which the number of white persons of each sex in that city and county at the time of the census of 1830, in each of the thirteen intervals of age, stated above to have been adopted throughout the United States at that census, is given; and the same information is given as to the coloured population at that time, but distributed into the six intervals of age only, above stated to have been adopted for them. The number of whites was 173,345; of coloured persons, 15,595; total, 188,940.

A statement of the deaths which took place within the Bills of Mortality during the term of ten years 1821-1830, is also given for the whole population without distinction of colour or sex, and distributed into the following sixteen intervals of age in which they happened, viz. under one year, between one and two, between two and five, then in each of the three intervals of five years each to twenty, and the remaining ten intervals of ten years each between twenty and a hundred and twenty; thirty-two persons having died between a hundred and a hundred and ten years of age, and five between a hundred and ten and a hundred and twenty. The whole number of those deaths, which did not include the still-born, was 37,914.

The number of births of each sex in each of the ten years 1821-1830, is also given, including the still-born, but without distinction of colour; and the number of still-born for each year separately, but without distinction either of colour or sex.

The number of deaths in each of the ten years is stated separately, both with and without distinction of sex, but always without distinction of age; and it is only where the whole number of deaths of both sexes without distinction, in each of the ten years is stated, that the division of it into

¹ In consequence of the notice which was taken in the first edition of this article, published in the Supplement to the Encyclopædia Britannica, in June 1817, of the enumerations of the people, and the published extracts from the parish registers in the United States, with some suggestions for improving the best of them, those of Philadelphia, and increasing their usefulness, John Vaughan, Esq., the Librarian of the American Philosophical Society, had the goodness to communicate to the author in June 1818, most of the information given above, as to the state of things down to that time, both in the United States generally, and in Philadelphia in particular; with eight of the annual statements (all he could procure and part with,) of the Board of Health in Philadelphia, showing the number of deaths at every age by each disease or other cause, in that city and its liberties; and several American newspapers, showing the number of deaths in each of the same intervals of age, the number in each month of the year, and the number of deaths by each cause, without in this last case, stating at what ages they happened, in *Baltimore, Boston, Charleston, New York, Philadelphia, Salem, and Washington*; for which the author feels it incumbent upon him to acknowledge his obligations, and express his gratitude in this place.

Mortality, Bills of. the numbers of white and coloured persons is given; in these numbers of deaths without distinction of age, the still-born are included. So that these documents do not enable us to determine out of how many persons of each sex, one died annually during the ten years 1821-1830.

Taking the limits of the Bills of Mortality from Dr. Emerson's second table, where he stated the wards and districts from which the returns of interments were made, and the population of each at the census in 1820, amounting in all to 121,980; and assuming the limits of the bills to have been the same in 1830, the population within them at the census of that year, was, according to Hazard's Register, 171,212; and the mean number of the people during the intervening ten years, appears to have been 146,596.¹ The number of deaths in the same time, exclusive of the still-born, was, according to the statement with the ages, 37,914; according to that without the ages, 37,814; taking 37,864, the mean between these for the true number, we find that there died annually on an average of those ten years, one person for every (38-7165 or nearly) thirty-nine in the whole population. The number of persons in the city and county at the census of 1820 was 137,097, at that of 1830, 188,961, mean number during the intervening ten years, 163,029.

The following statement of the progress of population in the city alone of Philadelphia, appears to be sufficiently interesting to deserve a place here.

In the year	No. of the people.	No. of square feet for each person.	No. of persons to a sq. mile.
1790	28,522	1755	15,885
1800	41,220	1216	22,926
1810	53,722	933	29,880
1820	63,802	786	35,469
1830	80,458	623	44,749

The three first columns are taken from the article above mentioned in Hazard's Register; but since the numbers in the third are proportional to the rarity of the population at the five enumerations, those in the fourth have been added, as they measure its density at the times of those enumerations.

The whole population of the city and county of Philadelphia, without distinction of age, sex, or colour, was distributed as follows, at the times of the enumerations in 1820 and 1830.

	In the year 1820.	In the year 1830.
In the city.....	63,802	80,458
In the suburbs.....	58,178	90,754
Total within the bills of mortality.....	121,980	171,212
In the rest of the county	15,117	17,749
Total within the city and county.....	137,097	188,961

(Hazard's Register, vol. viii. p. 65.)

Here the inhabitants of Blockley, amounting
in 1820 to 2655,
in 1830 to 3401,

Mortality, Bills of. are included within the suburbs and bills of mortality. It is much to be regretted that in the census of 1830, the coloured population were not distributed into the same intervals of age as the whites; also that the colours and sexes of those who died within the bills of mortality during the ten years, 1821-1830, were not distinguished in the published statements, as well as the ages. Dr. Emerson was of opinion that the rate of mortality amongst the coloured population was much greater than amongst the whites.

It is equally to be regretted that, while the bills of mortality extended only to the city and suburbs, of which the mean population during the ten years, 1821-1830, was 146,596, the enumeration of that portion of the population of the city and county distributed into the different intervals of age, with distinction of the colours and sexes, was not given separately. For with such documents as are before us, even if the enumeration of 1820 had been made exactly in the same manner as that of 1830; in attempting to determine the rate of mortality in any interval of age, we should only have the means of comparing the annual average number of deaths which took place in that interval within the bills of mortality, with the mean number of the people in the same interval of age in the whole of the city and county. But the mean population

within the bills of mortality was only..... 146,596
while that of the whole city and county was..... 163,029
that is..... 16,433
or about one-ninth greater.

The difficulty arising from this would not be great, if the population without the bills were known to be distributed into the different intervals of age in a manner similar to that within them; but there is no doubt of the distribution in the two cases being very dissimilar; for, excluding the still-born both from the numbers of the births and of the deaths, during the ten years ended with 1830,

The total number born within the bills of mortality was..... 61,945
Total number of deaths in the same time..... 37,814

Increase of population, within the bills, by procreation..... 24,131
While the increase from all causes during these ten years, was..... 49,232

So that the increase by migration must have been..... 25,101

within the bills of mortality; that is, one twenty-fourth part greater than by procreation. The part of the county without the bills certainly could not have been increased in a like proportion in the same way; therefore the population without the bills must have been much more dense at early ages, and more rare at the advanced ones, in comparison with the population within them, than in proportion to the mean number of the people of all ages, without and within the bills respectively. Whence it is manifest that nothing but enumerations of the people in each interval of age, within the limits of the bills, at each extremity of the period for which the annual deaths at the different periods of life are given, can make either those enumerations or the registers of deaths, available for the most important purposes they can be applied to.

In pursuance of an act of Parliament (41 Geo. III. cap. 15), an enumeration of the people in Great Britain was made in 1801; also returns of the baptisms and burials in England and Wales, during the year 1700, and every tenth year after that till 1780, then for every year to 1800 inclusive, with the number of marriages in each year, from the commencement of 1754 to the end of 1800. Large and clear abstracts of the answers and returns to this act were printed

¹ Including the township of Blockley in the limits of the bills according to Dr. Emerson, although in the register it is removed from them and placed in the rest of the county. If the interments in or from Blockley were not included in the bills, the annual average mortality must have been one of 37-9167.

Mortality,
Bills of.

by order of the House of Commons in 1802, and occupy more than one thousand pages folio. In 1811, another act (51 Geo. III. cap. 6), was passed, "for taking an account of the population of Great Britain, and the increase or diminution thereof;" in consequence of which, returns were that year made to Parliament, of the number of persons in every part of Great Britain; also of the numbers of baptisms, burials, and marriages in England and Wales, during each of the preceding ten years; very satisfactory abstracts of these were also printed by order of the House of Commons, in 1812, with some preliminary observations, in which corrections of the preceding returns are given.

The sexes were distinguished both in these enumerations and extracts from the registers, but the ages in none of them; and the proportions of males to females among the living are not to be depended upon, a number of males in the army and navy, which it is difficult to estimate, not being natives of Great Britain, nor usually resident there. The returns of baptisms and burials were also defective, but few registers of Dissenters having been included in them.

These abstracts are, however, with respect to the objects they extend to, more minute and satisfactory, than any other accounts of the same kind that had previously been published; and it was very desirable that such returns should have continued to be made, and abstracts of them to be printed at regular intervals; for nothing is so well calculated to shew the influence of different causes on the prosperity of a nation, as the comparison of the different states of the population, and the rate of its progress or declension, under different circumstances; besides, the value of the abstracts, once obtained, will be much enhanced by the publication of others of a similar kind thereafter.

It is much to be regretted, that no information as to the ages of the living, or those at which the deaths took place, was required by either of the acts above referred to, nor any encouragement or facility afforded to those who might be disposed to collect such information; and, consequently, that none was given in the returns.

Without better regulations for the keeping of mortuary registers than those heretofore in force, without such as should extend to dissenters of every denomination, it would probably be better not to require returns of the ages of the deceased from all parts of the kingdom; for defective or inaccurate returns would only mislead; and, not to mention the difficulty and expense of procuring returns of the ages of all the living, they would be comparatively of little use, where those of the dead were wanting.

But if government were to print forms for making returns both of the numbers of the living and of the annual deaths in proper intervals of age, throughout the extent of life; only sending these forms along with those now in use, to such as should apply for them; then persons who take an interest in such inquiries, and have the means of making correct returns, might do so with advantage. And a summary of all of that kind made from different parts of the kingdom, would convey much important information. Returns also, from such places only as were similarly circumstanced, might be collected into as many summaries as there were material varieties in the circumstances; and thus would afford the means of determining the different modifications of the law of mortality, which different circumstances produce. If the diseases that occasioned the deaths were also inserted, the greater prevalence of particular diseases in some circumstances than in others, would be apparent, with their effects, and the probable means of preventing them, or lessening their mortality.

But, *the population enumerated must always be precisely that which produces the deaths registered; the grand des-*

ideratum being, to determine the number of annual deaths at each age, which takes place among a given number of the living at the same age.

Mortality,
Bills of.

Mr. Milne's *Treatise on Annuities and Assurances* was published in 1815, and contains clear abstracts of the most important statements of this kind that had been published between Dr. Price's time and the date of its publication; these will, we believe, be found to be much more valuable than any thing of the kind that was extant when that respectable author wrote, whose work had long been referred to for the best information on such subjects.

Since the first publication (in 1817¹) of what has been stated above respecting the two first enumerations of the people in Great Britain, and the extracts from the parish registers of England and Wales, two² other enumerations have been made in 1821 and 1831; and abstracts of the answers and returns under the acts that required them, (1 Geo. IV. cap. 94, and 11 Geo. IV. cap. 30), have been printed by order of the House of Commons, (in 1822 and 1833 respectively.) The extracts from the parish registers, shewing in each case the numbers of births, marriages, and burials, returned for each of the ten years next preceding that of the enumeration. The principal difference between the queries put at the two enumerations of 1811 and 1821 was, that in 1811 no inquiry was made as to the ages of the people, while in 1821, after nearly the same questions had, according to the act, been put to the overseers in England, and to the schoolmasters in Scotland, the following instructions as to the ages of the people were given: "If you are of opinion that in making the preceding inquiries, (as to the number of families and persons), the ages of the several individuals can be obtained in a manner satisfactory to yourself, and not inconvenient to the parties, be pleased to state the number of those who are under five years of age," &c. The thirteen intervals of age into which the persons of each sex separately were to be distributed, being these: 4 of 5 years each from birth to 20 years of age; then 8 of 10 years each to 100; the thirteenth including all those above 100 years of age. Thus it was left optional with the returning officer whether this important question should be put, and with the party interrogated, whether it should be answered or not; from which it would appear that this part of the inquiry was not intended to be made with much correctness, and those whose onerous duty it was to put the question in populous places, might easily lighten the burden; accordingly, from such places the ages of a considerable part of the population were not returned. None were obtained from Manchester, Newcastle-upon-Tyne, or Sunderland. The proportion of the ages which were not returned was, in Birmingham, about $\frac{3}{4}$ ths, in Leeds, $\frac{1}{4}$ th, in Bristol, $\frac{1}{5}$ th of the returned population. In Middlesex, $\frac{1}{4}$ th, York, east riding, $\frac{1}{4}$ th, north riding, $\frac{1}{4}$ th, in Lancashire, $\frac{1}{4}$ th, in Warwickshire, $\frac{1}{4}$ d, evidently owing to the large manufacturing towns they contain, especially Birmingham, the population of which is more than a third of that of the county of Warwick. These deficiencies in the returns may reasonably be ascribed to the option which was offered to the overseers, who, however, performed the duty imposed upon them with great good will and attention, as appears by the complete return of ages where the obstacles were not too great.

That the people were not unwilling to state their ages, may be inferred from the complete returns of them from Hull, Liverpool, Portsmouth, Plymouth, and Great Yarmouth, as well as from every city in England, if we mistake not, except London, Canterbury, and Bristol. From the counties of Bedford, Chester, Rutland, and Leicester, nearly the whole were obtained; and from those of Lincoln, Norfolk, Suffolk, and Wilts, the deficiency was only on an aver-

¹ In the Supplement to former editions of this work.

² For the more recent statistics on mortality, see Appendix to the present article.

Mortality, age about one-thirtieth, while from all Wales it was only a forty-second part of the whole.¹

The following table may throw some light on the influence of large manufacturing towns, migration, and some

other circumstances, in producing a more or less complete return of the ages of the people at that enumeration. It being borne in mind that from Glasgow the whole were returned.

Omitting the army, navy, marines, and seamen in registered vessels.

	Both sexes. 100 ages were not returned out of	For every million of each sex, the number whose ages were not returned, was, of		Excess of Females.	Excess of Females for every 100 males.

With regard to the extracts from the parish registers, the principal difference between the questions put in 1831 and at the three preceding decennial periods of enumeration, was, that in these no inquiry was made as to the ages at which the deaths happened, while in 1831 the officiating minister of every church or chapel was requested to state the ages of the individuals of each sex entered in his burial register, during each of the eighteen years 1813—1830, in consequence of which the ages of 3,938,496 persons buried during those eighteen years were returned, 1,996,195 males, and 1,942,301 females. The number of each sex separately, and of both sexes, who died in each year of age during every one of the eighteen years, in all England and Wales, according to the returns, were given in the preface to the *Enumeration Abstract*, (pp. 36–42); besides which, a similar table was also given for each county separately, and sometimes for its principal town, at the end of the returns from that county, in the *Parish Register Abstract*.

Omitting the army, &c., as above mentioned, the whole returned population in 1821 was 11,978,875 persons; but the ages of 10,530,671 only were obtained, the number of persons whose ages were not obtained having been 1,448,204. As the ages withheld were generally those of residents in large manufacturing towns, whilst those returned were from the rest of the population, and a considerable proportion of the former class had migrated from the latter, many of them probably about the age of puberty; there are good reasons for believing that the ages returned and those omitted were not similarly distributed, as to their numbers, into the different periods of life; so that, although the total number omitted be given, they cannot be interpolated in their proper places by calculation or otherwise, among the ages returned.

In the returns of burials at different ages, there are also omissions, which can only be guessed at. Thus it appears that these documents, after all the pains and expense they have cost, do not afford the means of determining the law of mortality, although that undoubtedly is the most important purpose to which enumerations and registers of these kinds can be applied.

The act 6 and 7 Wm. IV., cap. 86, passed in August 1836, is likely to secure satisfactory records of marriages, births, and deaths, in England; but the abortive and still-born should be distinguished from the children born alive,

which does not appear to be provided for. They may, indeed, be entered as abortive or still-born, under the cause of death, in the register of burials; if that be done, they should be carefully excluded from the number of deaths, in making extracts or returns, and stated separately. And if, at the future decennial enumerations, the ages of the people be determined with corresponding accuracy, the values both of the enumerations and registers will be greatly enhanced, and the law of mortality, with much other important information, may be derived from them. The insertion of the cause of death, in the register of it, is of itself a great improvement.

As has already been observed in the article *ANNUITIES*, (in volume iii.), it is much to be regretted that in the population returns of 1831, the people were not classed according to their ages, as in 1821; but without giving any option either to the party by whom or to whom the question on that subject was required to be put, as to putting or answering it. It appears highly probable that there would be no occasion to impose any penalty for refusing to answer that question, or for giving wilfully an incorrect answer; and in the few cases where it might be so given, or altogether withheld, if a memorandum were made of it, the desired information might afterwards be obtained nearly enough from other parties; if it came but within the right interval of age, that would be sufficient. It is true that in the present defective state of the returns of births and deaths, that would not have enabled us to determine the law of mortality in a satisfactory manner; but with the returns of 1821, and those of a similar kind to be made at the future enumerations, it would have been of great use. Indeed it must be obvious to all, that one of the greatest uses of such periodical inquiries into the state of the population, is to ascertain its progress, by comparing the returns at the several successive periods, which can only be done satisfactorily when the same method of proceeding is adhered to at each, or as nearly so as may be consistent with the introduction of improvements into it.

Dr. Robert Watt's *Inquiry into the Relative Mortality of the Principal Diseases of Children, and the numbers who died under ten years of age in Glasgow during the thirty years 1783–1812*, forming the appendix to his *Treatise on Chincough*, was published with it, in 8vo. in 1813.

He states, (p. 336,) that, "on inquiring into the state of

¹ Those above mentioned are only a few cases, others may be easily found in the *Population Abstract*. The ages of the inhabitants of London within the walls were very nearly all returned; those of Canterbury were deficient by $\frac{1}{4}$ th part of the whole.

Mortality,
Bills of.

the Registers of the City, he found something of that kind had existed from a very remote period ; but that it was only from the commencement of the year 1783 that they had been kept in a regular manner." The Bills extended to the suburbs as well as the city, and he stated that so early as the year 1798, more than half of the funerals were without the city. With the most laudable zeal and unwearied industry, he collected from the different registers of burials contained in fifteen folio volumes, for every one of those thirty years, the number of children under ten years of age who died in each month of that year, by each of eight different diseases, (counting fevers of all kinds as one disease only, designated by the term *fever*, according to the bills,) the number of the abortive and still-born, and the numbers of deaths under two years of age, between two and five, and between five and ten ; and gave a separate table exhibiting those particulars for each of the thirty years ; shewing also the total number of deaths during the whole of each year from each of the causes, and in each of the intervals of age above mentioned ; with the whole number of deaths at all ages, and from all causes that took place in each year.

Then, dividing the whole term of thirty years into five periods of six years each, he gave a table (his 31st) shewing how many deaths took place in that period from each of the causes and in each of the intervals of age above mentioned, for every hundred in the whole numbers of deaths, including the abortive and still-born, which took place during the same period.

The following are four of the fifteen columns in that table.

Period of six years.	For every hundred in the total number of deaths during that period, there were caused by		
	Small-pox.	Measles.	Stopping or croup.
1783—1788	19.55	0.93	2.54
1789—1794	18.22	1.17	3.33
1795—1800	18.70	2.10	2.47
Gratuitous vaccination commenced in Glasgow in 1801.			
1801—1806	8.90	3.92	4.93
1807—1812	3.90	10.76	5.18

Dr. Watt, in common with almost all others who have well considered the subject, was an advocate for vaccination ; and if he overrated the degree in which the reduction of mortality effected by it was counteracted by the contemporaneous increase of mortality from other diseases ; he has given abundant proof that it was neither from the want of an earnest desire to discover the truth, nor of persevering industry in the pursuit of it.

At the conclusion of his work he recommended scarlatina to be thenceforward carefully distinguished from other fevers in the bills, and expressed his opinion that it had been a very considerable cause of mortality among children for some years previous to the date of his publication.

Medical men in general, both in London and in Glasgow, dissent from the opinion of Dr. Watt, that the mortality from measles had materially increased since the introduction of vaccination ; but it is supported by the Bills of Mortality both of London and Sweden, as well as those of Glasgow ; the increase has also been observed both in Cornwall and at Plymouth, although the numbers there are small.¹ Perhaps this increase of mortality may take place principally

among the children of the poor, who, in such cases, seldom have proper medical assistance ; and either from ignorance or necessity do not sufficiently protect the patients from cold whilst labouring under the disease.

The third edition of Dr. Cleland's *Statistical Tables relative to the City of Glasgow*, was published there (in 8vo.) in 1823, containing a good account of the population and mortality both of the city and suburbs down to that time ; he there gave the bills of mortality of the city and suburbs for the year 1822, which appears to have been the first published, and continued to prepare these bills during fourteen years, 1821—1834, with great care and attention, and to publish them in the Glasgow newspapers, with the approbation of the magistracy, who cheerfully defrayed the expense.

These bills were similar to those published by Dr. Haygarth at Chester, and by Dr. Heysham at Carlisle ; except that the intervals of age the numbers of deaths were given in under five years, were much less minute, and that the causes of death were not stated in Dr. Cleland's bills. That gentleman was also appointed to superintend the two enumerations of the people in the city and suburbs of Glasgow in 1821 and 1831 ; and having been appointed on this last occasion by the sheriff of Lanarkshire to superintend the enumeration of the county also, in a letter to the author of this article, dated February 15th 1831, he expressed his apprehensions that he should not be able to give a classification of the inhabitants of Glasgow and its suburbs according to their ages at that enumeration in the same manner as in 1821 ; but upon being informed, in reply, that in that case all the labour he had bestowed upon the parish registers during the ten years then elapsed would be fruitless, he answered, that, notwithstanding the extra trouble, he would prepare fresh schedules, and give the number of the people of each sex in each of the same intervals of age as in 1821, which he did accordingly ; and that is the only instance, except the Carlisle enumerations in January 1780 and December 1787, of its having been done in this country.

In the year 1831, Dr. Cleland published, in a folio volume, his *Enumeration of the Inhabitants of Glasgow and Lanarkshire*, including all the details of his labours above mentioned, and, in 1832, a second edition of nearly twice the bulk ; in the first, the bill of mortality for each year of the ten, 1821—1830, is given ; but in the second, only those for the first and the last of them.

The following is an extract from the folio volume, (first edition, p. 11.) "From my official situation I am enabled to state, that the books of the church-yard wardens are kept with such perfect accuracy that every reliance may be placed on the number of burials in the city and suburbs."

Since the year 1834 the Glasgow bills of mortality have been prepared by Henry Paul, Esq. convener of the Committee of Churches and Church-yards, under the superintendence of a committee of the magistrates and town council, with some material improvements upon those of Dr. Cleland. The bill for 1835 contains six tables, besides *General Remarks*, the principal improvements are in the third and fourth tables, which were not given by Dr. Cleland, in both of them the sexes are always distinguished ; in the third, the number of still-born children, and the number of deaths in each interval of age that took place in each month of the year is given separately ; and the sum of the monthly numbers shews the same thing in each case for the whole year. But the fourth table, which is still more valuable, shews the number of deaths of each sex in each interval of age, by each of the causes most easily discriminated.

Part of these two bills have been published in the Glasgow newspapers ; of that for 1836, in the *Scottish Guar-*

¹ *Sketch of the Medical Topography of the Hundred of Penwith, Cornwall*, by Dr. Forbes, part ii. p. 138, in *Trans. of Provincial Assoc.* vol. ii ; and Dr. Blackmore on the *Rise and Decline of Particular Mortal Diseases*, 8vo. Plymouth 1829, from *Trans. of Plymouth Institution*.

Mortality,
Bills of.

Mortality, *dian* of the 3d of February 1837; but only the contents of the first two of the tables above mentioned for that year had been published when this article was put to press, and the author acknowledges his obligations to Mr. Paul for the copies sent him by that gentleman of the papers already published. In these the intention of the council committee is announced, to improve as they proceed, the statements of the diseases by which the deaths were occasioned; also their intention to detail, in the future bills of mortality, the particular trades and professions of those who have died; and to give a table exhibiting the mortality among children from one month up to five years of age, with a statement of the various diseases which have proved fatal at those ages; all of which improvements are very desirable.

It is much to be regretted that only about one half of the births in Glasgow and its suburbs are registered, also that certain registers in the Barony Parish burying-grounds contain no record of the cause of death. The act passed in 1836, for registering births, deaths, and marriages, extends to England only; and the committee of the city council express their opinion that these defects cannot well be supplied without some legislative enactment.

In the bills of mortality for London, Glasgow, and too many other places, the still-born have been included among the burials, as the numbers are obtained from the burial registers; although, as was observed before, p. 525, col. 1, they never should be, for in that case they are generally included among the deaths in calculating the rate of mortality, in consequence of which, that rate comes out greater than the truth in the ratio of the whole number of the registerial burials to the number interred who had lived and breathed.

The *Observations on the Mortality and Physical Management of Children*, by Mr. Robertson of Manchester, were published (in 12mo.) in 1827; it is the first part only of that valuable work, namely, the observations on the mortality amongst children, which we have occasion to notice here; and we consider that no gentleman of the medical profession has treated it better, few, if any, so well. Mr. Robertson informs us that no bill of mortality is published in Manchester, and that, before the year 1812, the ages were not entered in the registers. He extracted, with great care, the numbers of deaths under ten years of age from the register of the collegiate church of Manchester, for the term of eight years, 1816-1823; and from the valuable register at the *Rusholme Road* cemetery there, for the term of four years, ended with April 1825. The results he has stated shortly, (p. 19.) with the proportion in each interval of age under ten, to the whole number of deaths in each register; and has given a valuable table, shewing, without distinction of sex, the number of children buried in the Rusholme Road cemetery during the four years 1821-1825, who died under one month old, between one and two, two and three, three and six, six and nine, and between nine and twelve months; also between one and two years, two and three, three and five, and between five and ten years old, with the total under ten; by each of forty-seven different diseases, and twelve other causes separately. The total number of deaths under ten having been 2056, and at all ages 3559.

We have already stated in the article *ANNUITIES*, (vol. iii. p. 203,) that Mr. Finlaison's Report to the Lords of the Treasury, on the mortality among government annuitants in this country, was printed by order of the House of Commons in 1829. Government having raised money at different times by the sale of life annuities, either by way of tontines, with benefit of survivorship, or otherwise; a separate register of the nominees or annuitants on whose lives the annuities depended, was on each occasion kept; the name, and consequently the sex, also the age, satisfactorily certified, of each nominee at the time when the annuity commenced, with the day of death, and the age attained,

were entered in the register. For each of these classes of nominees generally, but in some instances for two or three of the smaller ones combined, Mr. Finlaison has given a table, showing for each sex, 1. The number enrolled at each age last completed, during the observations; 2. The number alive of each age when the observations terminated; 3. The number who died at each age during the observations; and, 4. The number who passed on from that to the next greater age.

Mr. Finlaison calls each of his tables above mentioned an observation, although each records several thousands of observed facts or occurrences. Of these tables he has given twenty-one, but the recorded facts, which alone we have occasion to notice here, are contained in six only of them, the other fifteen being combinations of two or more of the six, or of selections from them.

These six are the following:—

Table.	Observations on the nominees of the	No. of	
		Lives.	Deaths.
I.	English Tontine, which commenced in July 1693, the last died in 1783.....	1002	1002
	The observations in all the other cases terminated in January 1826.		
II.	Life Annuities issued at the Exchequer in 1745, 1746, 1757, 1766, 1778, and 1779.....	2552	2396
III.	Three Irish Tontines of 1773, 1776, and 1778.....	3557	1993
IV.	Great English Tontine of 1789.		
V.	Selected by the contributors.....	3518	1315
V.	Drawn by lot, (Art. ANNUITIES, p. 207).....	4831	1823
VII.	Life Annuities chargeable on the Sinking Fund, commenced in 1808.....	6892	1548
	Totals,	22,352	10,077

In the article *ANNUITIES* (pp. 202 and 203) we mentioned the desire of the members of the Equitable Assurance Society to ascertain the law of mortality which had obtained among them; and that the late Mr. Morgan, their then actuary, had been able to form a table which had induced him to alter his opinion on the subject; accordingly, in February 1834, the Society printed for the use of the members a folio pamphlet of "Tables showing the total number of persons assured in the Equitable Society, from its commencement in September 1762, to January 1, 1829, distinguishing their ages at the time of admission into the Society, and exhibiting the number of years during which they have continued members of it, the periods of life at which their assurances have terminated, and the ages which the surviving members had attained on the first of January 1829. To which are added, Tables of the Probabilities and Expectations of the duration of human life, deduced from these documents; a statement of disorders (as certified to the Court of Directors) of which 4095 persons assured have died, in thirty-two years, ending December 31, 1832; and a Supplement, showing the mortality of the Society for the years 1829, 1830, 1831, and 1832." With an introduction by Mr. Arthur Morgan, who succeeded his father as actuary of the Society.

By these documents it appears that, of the persons whose lives were assured in the Society during the period of 66½ years from its commencement, till the end of the year 1828,

Mortality,
Bills of.

Mortality,
Bills of.

The number then surviving and continuing insured, was..... 6930
The number who went out of the Society during their lives, the assurances on them having been discontinued..... 9324

Carry forward 16254

Brought forward 16254
The number who continued assured till death... 5144

And that the total number of lives insured was 21,398
The most valuable of these data are contained in a table, marked A, of the following form, the ages stated being those last completed :—

Mortality.

31	785	2	31

The number in each column on the extreme right and left shows the age at which the lives in the horizontal line passing through it were insured; and each large column, with the age written over it, gives in its four subdivisions the information there expressed for each age of admission separately

1. The number of lives who attained that over-written age.
2. How many of them were living of that age when the observations terminated.
3. How many went out of the Society alive, by discontinuance of insurance at that age, during the observations.
4. How many of them died insured during the same time.

And as none of the last three descriptions of lives could have entered into the next greater year of age during the observations, while all the rest of the lives of the first description must have done so; if the sum of the 2d, 3d, and 4th numbers be subtracted from the first, the remainder, being the number who entered on the next greater age, is inserted in the first division of the column for that greater age.

The numbers in each horizontal line of the table always begin with the number admitted during the observations at the age of admission standing on the same line in the marginal columns; and the number admitted is placed in the first division of the column with the same age at its head; from which it necessarily follows that the number of lives insured at any age, is always the last number in the first division of the column with that age written over it. Thus, the numbers admitted of the ages 29, 30, and 31, were 783, 762, and 785 respectively. 785, the number admitted at 31, that is, in the 32d year of age, is greater than the number admitted at any other age, which shows that to be the time of life at which assurances were most frequently effected in the Equitable Society previous to the year 1829, and may be taken as a proof that they are most generally wanted at that age, although no such inference could be safely drawn from the records of that or any other office, during a period of twenty years or more, commencing with 1829, on account of the great diversity in the rates of premium required for life assurance by different offices, and in the advantages held out by them, since about 1825 or 1830. The numbers admitted at the four ages 29–32, vary but little. The three first are given in the above specimen of the table, that for the age 32 was 780; they decrease gra-

dually on both sides of that interval of age, so that from the commencement of the 30th to the end of the 33d year of age, appears to be the period of life in which most life assurances are applied for; probably also that in which most first marriages of men are contracted in this country.

There are in the table 70 ages of admission, beginning with 7, and ending with 88; but only ten lives were admitted after completing their 67th year. As the greatest age attained by any life assured, and that by one only, was 94 years completed, there are 88 columns with the ages from 7 to 94 written over them, each divided into four.

Thus, it appears, that in this very valuable table, which had long been wanted before it appeared, and is one of the many important benefits derived by the public from the Equitable Assurance Society; the progress of all the 21,398 lives through the different ages from seven to ninety-four, so long as they respectively remained insured, the respective ages at which they entered the society, and at which they went out of it, whether by death or discontinuance of assurance, are distinctly shewn, and the means of determining the law of mortality amongst the lives are given, even for determining it amongst those separately which were admitted at any one age, so far as their limited numbers will allow. Immediately after this, two other tables, undistinguished for reference either by number or letter, are given; the first exhibiting for each of the four divisions of every column with the age set over it, that age standing in the margin of this table on the same line, the sum of the numbers in that division set against all the ages of admission. The numbers in the first column of this table we consider to be of very little importance in comparison with those in the three other columns; they shew the number of observations of each kind obtained in each year of age, and consequently the different degrees of confidence the rates of mortality derived from them at different ages are entitled to. It shews, that between twenty and seventy-four years of age, the number of observations, or of lives passing into, and in whole or in part through each year of age, was always above 1,000; that number increased from the age of seven where it was forty, to the age of forty-three, where it attained its maximum of 7,725, and then decreased gradually to the age of ninety-four, where there was but one life left which did not reach ninety-five. But the same things were shewn, although not at one view, in table A, where the sum of the numbers in each column standing

Mortality,
Bills of.

against all ages of admission were given; therefore the numbers in that first column might well have been omitted, and the number of admissions at each age substituted for them; or if the first were retained, a column for the number admitted at each age should have been added, for then that table would have exhibited at one view, and in small compass, all the data necessary for determining the law of mortality.

The other small table merely gives the same information as the first, not for each year of age separately but for the interval between seven and ten, and then for every interval of five years of age between ten and ninety-five years.

A table marked B differs much from A both in its contents and value; it is stated to shew "the duration of the lives of those persons *only* who became members of the Equitable Society between September 1762 and January 1st 1829, and who either continued their assurances to the latter date or died during the intervening period;" all those lives the insurances on which were discontinued, having been omitted. But all of those omitted lives were, while insured in the society, subjected to the chances of mortality equally with the others which continued insured till they either survived the period in which the observations were made or became extinct. By the extract given above from table A, it appears that 783 lives were admitted at 29 years of age; but that table shews, that of these, 379 went out of the society during the observations by discontinuance of the assurances on them; the remaining 404 *only* are inserted in table B, as having been exposed to the chances of mortality in that year of age during the observations, and the three deaths which happened in the same year of age, are assumed to have taken place out of 404 instead of 783 persons admitted in the same year of age. The same number, 379 of those admitted at 29 years of age, also went out after the age of 30, which number being taken from 780, leaves 401; 334 of them went out after the age of 31, which, taken from 729, leaves 395; and in this manner table B has been formed from table A. The following extract from table B corresponds with that given above from table A.

Age of admission.	Age 29.		Age 30.		Age 31.	
	Living.	Died.	Living.	Died.	Living.	Died.
25	266	2	257	2	245	5
26	298	2	290	7	276	4
27	340	3	327	5	306	4
28	386	2	376	4	365	4
29	404	3	401	5	395	4
30	435	2	433	4
31	460	2

Let us now consider those lives only which were twenty-nine years of age when admitted, and since the number of deaths among them at that and each of the greater ages was the same according to both tables, whilst the number attaining the age 29, 30, 31 was, according to table A, 783, 780, 729, B, 404, 401, 395,

it is manifest that the mortality, at each age according to table B, will be greater than according to table A, in the ratio of the number attaining that age according to table A, to the number attaining the same age according to table B;¹ that is, at these three ages nearly in the ratio of

two to one. But the younger the lives are at admission the greater is the proportion of them who leave the society by discontinuance of insurance; and after the lapse of eight or ten years from the age of admission, the number of lives which leave the society in that way diminishes rapidly as the age increases, so that the two tables (A and B) approximate closer and closer as old age comes on, and differ but little after sixty.

It is also to be borne in mind that the numbers attaining the age of thirty, and dying of that age, are obtained by taking the sum of all the numbers in the first and last divisions respectively of the column in table A with 30 at its head, from seven, the least age of admission, to the age thirty, the mortality in which is the object of inquiry; and the higher in the column any number is, or the less the age of admission, the longer have the lives then thirty years of age been insured, both in table A and B. Hence it is evident that the error in excess of the mortality according to table B in any year of age (thirty for instance) will not be so great as among those lives only which were admitted at that age. And all that is shewn here, with regard to lives admitted at thirty years of age, and attaining that age, applies equally to those admitted at and attaining to any other age.

Those marked C and D are tables of mortality derived from A and B respectively; and two other tables, marked E and F, shew the expectation of life at every age from ten to ninety-seven years according to tables C and D.

After these a valuable table is given, shewing the number of deaths which took place amongst the persons insured in the society during the term of thirty-two years, 1801—1832, in each interval of ten years of age from ten to eighty and those above eighty, by each of forty-three different causes, as certified to the Court of Directors. The whole number of deaths during that term was 4,095, of which there were occasioned

By thirty-seven different diseases....	3,449
Natural decay of age.....	566
Childbirth.....	4
Accidents.....	40
Suicide.....	29
Murder.....	3
Being slain in war.....	4
	4,095

This table shows the comparative numbers of deaths by each disease at different ages, and from different diseases in the same interval of age; but not the rate of mortality from each disease in each interval of age; for this purpose, the annual average number of insured lives existing in the society in such interval of age during that term of thirty-two years is necessary, but unfortunately wanting. Lastly, as a supplement to Table A, a small table is given, showing for the intervals of age between 7 and 10, 90 and 97, and in each interval of 10 years between 10 and 90, the numbers living and dying in each of those intervals of age during each of the four years. Upon comparing the numbers living in the same intervals of age at the end of the year 1828 given in Table A, with those in this supplemental table, we infer that it was at the end of the year placed at the head of the column in this table that the numbers stated in that column were living in those intervals of age. But the only information given on the subject, is the word "Living" placed at the head of the column of numbers.

In the year 1832 was published a compilation in 4to, by Mr. Marshall, entitled, *Mortality of the Metropolis*, containing the London Bills of Mortality to the year 1830 inclu-

¹ Here we omit the deduction shewn in the section on the LAW OF MORTALITY to be necessary for the number of lives entering the society remaining insured when the observations terminated, and leaving it by discontinuance of insurance at each age. To make and to explain it here might perplex some readers, and the false views of the subject table B is calculated to give, are here, we trust, sufficiently exposed without it.

Mortality,
Bills of.

Mortality,
Bills of.

sive; with various statistical details taken from the enumeration and parish register abstracts of this country, with a few short notices of a similar kind relating to Spain and Portugal, Prussia, the Netherlands and Sweden, but without any distinction of ages, except for Sweden, and even for that population, only the numbers of deaths in the single year 1820, under one year of age, between one and fifteen, and those above fifteen.

Dr. Forbes's very valuable *Sketch of the Medical Topography of the Hundred of Penwith, comprising the district of the Landsend in Cornwall*, already quoted in this article, was published in the second and fourth volumes of the "Transactions of the Provincial Medical and Surgical Association," in the years 1834 and 1836. It is divided into two parts; and it is only the first chapter of the second part, which is contained in the volume of the Transactions published in 1834, that we have occasion to notice here. The progress of the population is first treated of, and the information on that subject is taken from the population abstracts at the four decennial enumerations of 1801-1831; but keeping the mining parishes separate from the agricultural. There are twenty-five small tables; in the first seven, the numbers of marriages, births, and deaths, are given, and compared with those of all England, and with particular parts of it, without noticing the ages of the deceased; but in the eighteen others the number of deaths in each decade of age from birth to a hundred years, and those above a hundred are given. On these Dr. Forbes makes the following observation: "Abstracts of all the registers in the hundred were made by myself, with the utmost attention to accuracy."

The publication of bills of mortality in Paris commenced during the administration of COLBERT, an epoch rendered memorable by so many useful establishments. That great minister proposed to the king to issue an order, that a bill for that city should be printed and published at the end of each month, containing in addition to what is usual elsewhere, the numbers admitted into the hospitals; there were also added short remarks on the character of the seasons, and the principal diseases which had prevailed; with the prices and weights of different kinds of bread, and some other objects of general consumption. The motive of this ordinance was thus expressed: "Estant important au public, pour la santé et pour la subsistance des habitants, d'en connoître l'état en tout tems, et d'observer soigneusement les causes qui augment ou diminue le peuple en chacun des quartiers de Paris, il sera fait, tous les seconds jours du mois, une feuille qui contiendra le nombre des baptêmes, des mariages et des mortuaires du mois précédent et de chacune des paroisses en particulier."

This ordinance was attended to for fifteen years, 1670-1684, but after the death of Colbert, which happened in 1683, it was neglected during twenty-four years, 1685-1708; the publication of the bills was resumed in 1709, and has been continued ever since, improvements having also been introduced into them from time to time.

This information is taken from a "Mémoire sur la Population de la ville de Paris depuis la fin du 17^e siècle," in the second volume of a great and important work printed by the French Government, but not for sale, entitled, *Recherches Statistiques sur la ville de Paris et le Département de la Seine; Recueil de Tableaux dressés et réunis d'après les ordres de Monsieur le Comte de Chabrol, conseiller d'état, préfet du département*.

The first volume was published in 1821, in small octavo,

and contains sixty-three tables; it is stated in the introduction, that lithography was made use of by the administration in the publication of the tables in that volume, to multiply the applications, and to encourage the exercise of that new art; probably this gave occasion to its being used as above mentioned in the large Swedish tables published in 1829. Three other volumes of this work have been published in quarto, with all the tables printed by types in the usual way; the use of tables for digesting and presenting the information collected is continued throughout the work, which, as is justly observed, admits of an immense number of results being brought together, excludes superfluous dissertations, and facilitates all comparisons. Topography, population, institutions, agriculture, manufactures, commerce, and finances; are all minutely detailed in so many separate chapters; but we have only occasion in this article to attend to the population; and on that subject shall notice principally those parts of the work, where the numbers of annual births, and the numbers both of the people and of the annual deaths, with the ages of the living and those at which the deaths took place, are stated.

An enumeration of the inhabitants of Paris was made in February 1817, and in the first volume, where the results of that enumeration are given; there is also given an extract from a report made to the minister of the interior, by the Count de Chabrol, dated the 3d of July 1818, explaining the manner in which it was effected. He states, that attempts had been made on several previous occasions to ascertain the population of Paris by an effectual enumeration; but that different circumstances had contributed to render the results very inaccurate. He gives reasons for which he considers it indispensable to obtain, not only for each house, but for each separate location, a distinct list with the christian and surname of each person of whatever age, the sex, (shown by the christian name), the state of celibacy, marriage or widowhood, and the condition, profession, or occupation of each; he explains minutely the measures that were taken to carry this into effect, and the checks used to ensure a great degree of precision. To avoid including the same person twice in the enumeration, the place of residence chosen for that of inscription was *the habitation during the night*, which rule was always strictly adhered to; to prevent the effects of changes it was desirable to complete the work as quickly as well might be; and in one month and ten days the enumeration of 657,172 persons was made at their places of residence in the manner stated above. This is called *nominative* enumeration.

But a part of the population from their continual change of place, could not be enumerated so correctly. These were foreigners, or native French subjects then resident in the capital, but without any fixed habitation, travellers, the inmates of twenty-seven hospitals,¹ civil and military, of ten prisons, of forty-three military establishments, of six hundred and ninety-two furnished hotels, of divers other establishments, and the persons with regard to whom the information obtained was insufficient; all of these persons are said to be numbered *collectively*, and no distinction is made either of their ages or sexes.

Of the persons enumerated nominatively, the number of each sex separately in each quinquennial interval of age from birth to thirty years completed, then in each decennial interval to a hundred, and of those above a hundred years of age was given. The whole numbers of them of all ages were these:

¹ As were also those for the three last months of the year 1684; and the bills for 1676 and 1677 are wanting; so that, altogether, there were twenty-seven years from the first publication of the bills, in which their publication was either interrupted or neglected, unless the two missing bills were lost, which is probable.

² Under which term we here include les Hospices et les Hôpitaux.

Mortality,

Those enumerated collectively amounted to...				56,794
and made the total population within the walls, Adding to this the population of the <i>Hospice</i> <i>de Bicêtre</i> , and of the <i>Maison de Retraite de</i> <i>Mont-Rouge</i> , which, though situated without the walls, belong to Paris.....				713,966
we have.....				3,246
				717,212

the whole population of Paris on the first of March 1817. An attempt was made to class according to their ages the persons who were only enumerated collectively, the ways in which the different estimates were made, are explained, and a table (No. 7.) of their results is given; but we consider them to be so uncertain, that we are not aware of any useful purpose they can be applied to, and therefore take no farther notice of them here.

It is also observed that the number of the living under five years of age, even in the nominative census, was much less than it should have been in consequence of the very great number of children which are sent to be nursed in the neighbouring villages, both by their parents and by public establishments, neither the mean number of them, nor the mean duration of their absence from Paris, could be ascertained, and any estimates that could be made on the subject were so uncertain that it would have been useless to state them.

The nominative census was also deficient in numbers after fifty years of age, on account of the number of aged poor who die in the civil hospitals. The approximations to the ages in these appear to be entitled to more confidence than in the rest of the collective census, and for those within the walls of Paris they are given in column sixth, whilst the numbers of the nominative census at the same ages are given in column seventh of table seven; and by them we find that the numbers were

In the nominative census.	In the civil hospitals.
At all ages.....657,172	12,596, about $\frac{1}{2}$ d part.
Above fifty years of age, 134,104	6,037, about $\frac{1}{2}$ d part.

From what has been stated above, it will be evident to those who understand the subject, or who read the next article, that this enumeration, although performed with great skill and labour, does not afford the means of determining the law of mortality in Paris, even if we had the most satisfactory accounts of the numbers of births and of the deaths that took place at all ages.

Paris being for municipal purposes divided into twelve districts called *arrondissements*, distinguished by so many numbers from one to twelve, and each of these into four quarters, Table III. shows for each *arrondissement* and for each quarter of it (giving also the names of the quarters),

the numbers of houses, of families,¹ and of persons, that were ascertained by the nominative census to be in it on the first of March 1817; also for each of the six descriptions of persons separately, mentioned above as those who were numbered collectively, how many persons were so numbered in each *arrondissement* and in each quarter of it. And in the last two columns of that table, the total number of persons in each *arrondissement* and in each quarter of it on the first of March 1817, is given; but there is no distinction of age or sex in this table.

Table IV. exhibits the number of the living ascertained by the nominative census to be then in each of the fourteen intervals of age above mentioned, with the distinction of sex and condition as to celibacy, marriage, or widowhood; the totals of which, omitting the ages, we have stated above.

Table V. shows for every 10,000 persons in each of the twelve *arrondissements*, how many were in each of the same intervals of age, but without distinction of sex or condition. The following tables to the tenth inclusive, relating to the numbers and proportions of the people, we do not think necessary to notice here particularly; the whole number of the tables relating to the population and extent of Paris is twelve, numbered from three to twelve, and including two as first and second supplements to table ten.

We now proceed to those parts of the work which exhibit what the French denominate the *mouvement*, but we call the *progress*² of the population; which is shown by statements of the numbers of annual marriages, births, and deaths, during a series of years, with the ages at which the deaths happened.

The volumes these documents are contained in, and the years in which the events recorded took place, are as follow:

No. of Vol.	Published in the year.	Years reported upon.	
I. 8vo.	1821	2	1817 and 1818
II. 4to.	1823	3	1819 — 1821
III. 4to.	1826	2	1822 and 1823
IV. 4to.	1829	3	1824 — 1826

There are able introductions and memoirs prefixed to all the volumes, which it would not be consistent with the objects of this article to notice further here; except the memoir already mentioned on the progress of the population of Paris during the 17th, 18th, and 19th centuries; which we now resume.

Before 1710 the numbers of foundling infants were, or at least can only now be found, recorded, for the years 1670, 1680, 1690, and 1700; but the publication of the bills of mortality having been resumed in 1709, the number of foundlings was stated in them for 1710, and every following year. The sexes were not distinguished either in the numbers of births, deaths, or foundlings, till the year 1745; after which it was always preserved; it was only from the year 1795 that the numbers of still-born children were recorded separately, and we are not informed whether they were previously included among the births or deaths, or both or neither of them. 1806 was the first year in which the illegitimate children were distinguished from the legitimate; they had previously been put together without distinction. This information is taken from the table in the second volume numbered 53, (and the notes that ac-

¹ The French word is *Ménage*, and to render *family* synonymous, we have, we believe, only to extend its meaning to the case of a single person residing and conducting all his or her domestic affairs alone; whether occupying the whole of a house or only a part of it.

² The *mouvement* or *motion* of the population would be the better term if it were admissible in English, as it applies equally whether the number of the people is increasing or decreasing.

Mortality,
Bills of.

Mortality, company it) showing the numbers from the year 1670 to 1821, with the exception of twenty-six years above mentioned necessarily left blank, and another which was defective.

The progress of the population of Paris during each of the ten years 1817—1826, as exhibited in the four volumes above mentioned, is contained in ten tables. In the first six there is no distinction of ages.

The *first* shows the numbers of births, marriages, and deaths, that took place in each month of the year, without reference to place; and then those which took place in each of the twelve arrondissements of Paris, without reference to the months of the year which they happened in; the sexes being distinguished both in the births and deaths.

The *second* shows the same things in greater detail; the columns of the first table being subdivided in this, so as to show how many both of the births and deaths took place at home, and how many in the hospitals; also, of each of these two descriptions of births, how many of the children were legitimate and how many illegitimate.

The *third* is confined to natural children; and with regard to them, the same information is given as to the sexes, and the months and arrondissements in which they were born; but in addition to this, it is shown how many of them were acknowledged at their birth, and how many were not; also how many were acknowledged by celebration of marriage, and how many after birth, before a magistrate.

The *fourth* shows the number of still-born children of each sex, during each month, and in each arrondissement.

The *fifth* shows the number of marriages in each month and in each arrondissement, which were given without further particulars in the first table; but here, the number of marriages in each horizontal line of that table, is shown to consist of four different numbers of so many different kinds of marriages. Thus:

	1	2	3	4	Total as in Table I.
	Between Bachelors and		Between Widowers and		
	Maids.	Widows.	Maids.	Widows.	
The totals in the city of Paris in the year 1826, were,	6457	368	708	222	7755
In the arron- dissement of St. Denis,	732	60	83	26	901
Arrondisse- ment of Sceaux,	584	44	77	27	732
Grand Totals in the capital or depart- ment of the Seine.	7773	472	868	275	9388
	8245		1143		
	9388				

Hitherto for the sake of perspicuity, we have taken no notice of the rural arrondissements of Saint Denis and Sceaux; but we add them here, to show the way in which the numbers for them are introduced in all the first six tables, after the totals for the city of Paris are obtained; and by adding them to the totals for the city, the grand or general total is also obtained for the whole of the capital, or department of the Seine. The last four of the ten tables relate to the city of Paris only.

The *sixth* shows the deaths in each month and arrondissement, the same as the first; but each column in the

first table is so divided in this, as to show how many of each sex died at home, also how many in the civil, how many in the military hospitals, and how many in prisons. In this and the first table of deaths, the dead bodies deposited at the Morgue within the year, are added to the sum of the deaths both in the different months of the year, and in the different arrondissements within the walls of Paris, to obtain the total number of deaths in the city.

The *seventh* table we consider as being the most valuable of the ten. It shows, for the city of Paris only, the numbers of deaths in the first and second quarters of the first year of age, also in the last half, consequently in the whole of that year; then in every following year of age separately, to that of ten years completed; and after that in every interval of five years of age to a hundred, and those above a hundred; always distinguishing the sexes, and showing the numbers who, in each interval of age, died unmarried, married, widowers or widows.

Were it not for the salutary practice of sending children born in Paris into the neighbouring villages to be nursed; as the numbers of births of both sexes are given, and also the numbers of deaths of both sexes separately in minute intervals of age under ten years; the law of mortality among them might be determined, even independent of enumerations of the living. But under the actual circumstances, that very desirable object cannot be attained.

The *eighth* shows the numbers of violent and accidental deaths, voluntary and involuntary, in each of various ways, which took place in the city of Paris in each month of the year, and in the whole year; the sexes being distinguished in each of the numbers for the whole year, but not for each month.

The *ninth* shows the number of suicides attempted during the year, in the department of the Seine; the number of those attempted which were effectuated, and the number of them which were prevented; with the means of destruction employed, and the presumed motives of suicide. The sexes are also distinguished, and the married from the unmarried.

The *tenth* shows the number of deaths from small-pox in each month of the year, and in each arrondissement in the city of Paris, without distinction of age; also the number of them that took place in each of the intervals of age employed in the seventh table, without distinction of months or arrondissements; the sexes being in all these cases distinguished. Then the number of gratuitous vaccinations during the year, in each arrondissement, is shown. The sexes of the vaccinated were distinguished for the years 1817 and 1818, but not afterwards. Each of the two tables here numbered 9 and 10, was, for the years 1817 and 1818, divided into two; so that the number showing the progress of the population in those two years, was twelve instead of ten.

In addition to these, a table numbered 37, in the first volume, is too curious and interesting to be passed unnoticed here. It was formed from extracts made by *M. Benoiston de Châteauneuf* from the statements of deaths prepared in the mayoralities of the different arrondissements; which statements were founded on the declarations made by the physicians and surgeons who certified the deaths.

The table shows, for each of the four years, 1816—1819, the number of deaths produced in the city of Paris, by each of the following pulmonary diseases: Asthmas, catarrhs, defluxions on the chest (*fluxions de poitrine*), and consumptions (*phthysies*); in the spring, summer, autumn, and winter of each year, without distinction of age; but also in each interval of ten years of age from birth to seventy years, between seventy and ninety, and between ninety and a hundred; without distinction of seasons. The total by each of these diseases in each of the four years is also

Mortality,
Bills of.

Mortality,
Bills of.

stated, with the total number of deaths in Paris from all causes during the same year; and the proportion of the mortality from each of those pulmonary diseases to the whole mortality; the sexes being distinguished throughout. No table of that kind, nor of the deaths by other diseases than the small-pox, was inserted in any of the other three volumes. Statements of the annual average progress of the population in each of the arrondissements of Paris during the five years 1817-1821 are given in the third volume, tables 42-50; and for the next following quinquennial period 1822-1826 in the fourth volume, tables 54-62. Table 102 of the second volume shows the comparative riches of the different arrondissements in the city of Paris; it was constructed from the register of personal taxes imposed in the year 1820; that table with the others above mentioned in the first three volumes, were the principal data on which M. Villermé founded his very valuable *Mémoire sur la Mortalité en France dans la classe aisée et dans la classe indigente*, in the first volume of the *Mémoires de l'Académie Royale de Médecine*, tome i. 1828.

In the introduction to the fourth volume of the *Recherches Statistiques* it is stated, that a fifth would terminate the work; and a short account is there given of its intended contents; but in May 1837, when this article was printed, that volume had not appeared.

Statements of the progress of population in Paris and in every department of France, are regularly published in the *Annuaire du Bureau des Longitudes*, also of the population of the different departments, and of their arrondissements and chief towns, but without any notice of the ages. The numbers of deaths in the city of Paris of each sex by the small-pox at the different ages, have also been inserted in the same work, for 1817 and every subsequent year; but not the numbers gratuitously vaccinated.

The ages at which the deaths happened are not given in any of the statements in the *Annuaire*, except those for the city of Paris.

In February 1835 was published at Troyes, the capital of the department of the Aube in France, *Recueil des principaux travaux des Conseils de Salubrité du département de l'Aube*, containing the same kind of information, given in the same manner, but rather more fully respecting the progress of population in Troyes, as is given in the *Recherches Statistiques* for the city of Paris; except that there is no mention made of still-born children, or of the deaths from small-pox, or of the numbers gratuitously vaccinated.

The statements of the deaths in all the intervals of age, are given not only for each year, but for each month of each of the ten years 1821-1830; also in one table, those in each month during the whole term.

These documents were derived from the bills of mortality by Dr. Patin, president of the council for the arrondissement of Troyes.

The population of the place at the commencement of the term was 25,076, at the end of it 23,749, of whom 10,626 were males, and 13,123 females. The ages of the people do not appear to have been distinguished at either of the two enumerations made at the commencement and at the end of the term; neither are the total numbers of the two sexes who were living at its commencement given separately. So that the law of mortality cannot be determined from the data obtained.

The three following tracts relating to the Netherlands, were all published at Brussels in 8vo:

1. In the year 1827 a Memoir on National Statistics, entitled, *Développement des trente et un Tableaux publiés par la Commission de Statistique, et relatifs aux mouvemens de la Population dans les Pays-bas, depuis la création du Royaume*

jusqu'à 1824 inclus; par Edouard Smits, Secrétaire de la Commission, &c. &c.

Mortality,
Bills of.

The tables shew the numbers of persons on the first of January 1815, and on the thirty-first of December 1824, residing in the towns, and in the rural communes separately, for each of the nineteen provinces in the kingdom; with the numbers of them for the whole kingdom of the Netherlands taken together. They also show what the number of the people with the same distinction of town and country residence, was on the first of January in each of those ten years; with their mean number during the first and second halves of that period, and during the whole of the same period; but in these numbers of the people there is no distinction made either of age or sex; the number at the end of 1814 is stated (p. 2) to be *estimated*, and that at the end of each year after it, was found by adding the excess of the births above the deaths in the same year, to the population at the end of the preceding; so that the numbers of the people there stated, are not entitled to much confidence.

The progress of the population is also shewn by statements of the numbers of births, marriages, divorces, and deaths, and the differences between the numbers of births and deaths during each of the ten years for the whole of the kingdom; and for each province during the whole of the ten years, the inhabitants of towns being distinguished from those of the country, and males from females, in all that relates to the numbers of births and deaths. The proportion between the sexes in the numbers both of births and of deaths, and that of the annual births as well as of the annual deaths, and of the difference between them to the whole population, in the towns and the rural communes jointly and separately are given, for the whole term of ten years, the two periods of five years each, and for each year of the whole term.

2. In the same year (1827) *Recherches sur la Population les Naissances, les Décès, les Prisons, les Dépôts de Mendicité, &c. dans le royaume des Pays-Bas*, par M. A. Quetelet, *secrétaire de la commission de statistique du Brabant-méridional, &c.* M. Quetelet (p. 2) states the population on the 1st of January 1825, to have been estimated at 5,992,666, which falls short of 6,013,478, stated by M. Smits, by 20,812; and that this estimate was founded on two partial enumerations of the people made previously, one under the imperial government, the other about the commencement of the then (in 1827) actual government; and that from these, and the numbers of annual births, the estimate was made in the manner proposed by Laplace.¹ He states that the data they then (in 1827) had, could only be considered as provisional and wanting rectification. There is little more in this tract that we can properly notice here, as it is chiefly on subjects not within the scope of this article; but the note A at the end, by M. Le Baron de Keverberg, contains some good observations on enumerations of the people.

3. In 1832, *Recherches sur la reproduction et la mortalité de l'Homme aux différens ages, et sur la Population de la Belgique*, par MM. A. Quetelet et Ed. Smits, (*premier recueil officiel*). An enumeration of the people in Belgium was made in November and December of the year 1829, but owing to the partial occupation of the provinces of Limburg and Luxemburg, the information obtained respecting them, especially the latter, was incomplete. The whole number of the people on the 1st of January 1830 was found to be 4,064,209, of whom 998,118 were resident in towns, and 3,066,091 in the rural communes. The people were throughout classed according to their residence in town or country, their sexes, and their state of celibacy, marriage or widowhood.

The authors state (p. 13) that in the tables of enumera-

¹ *Théorie Analytique des Probabilités*, p. 391, and *Essai Philosophique sur les Probabilités*, p. 45. It was first adopted by the French government in 1802.

Mortality,
Bills of.

tion the ages of the inhabitants were carefully specified; but although we consider this to be of much more importance than any other part of the inquiry, the information they have given on this subject is far from being satisfactory. In every other place of any considerable magnitude where this important and laborious operation has been performed; in Sweden, Spain, Carlisle, Paris, Great Britain, Glasgow, and Philadelphia, a distinct statement of the *absolute* number of persons found to be in each interval of age at the time of the enumeration has been published; and in some cases, as in those of Carlisle, Paris, and Glasgow, the manner of proceeding and the checks employed to ensure a considerable degree of accuracy have been explained. But in the case of Belgium, all information of this kind has been withheld, and the authors have only given us (p. 16) a table shewing the *relative* numbers of the people in the different intervals of age. For every million of them it shews for each sex separately, and for each of forty-seven ages from birth to one hundred years inclusive; how many were above that age, and also how many of these were in a state of celibacy, marriage, or widowhood.

Although the professed object of the authors was to treat of the mortality at the different ages of human life, they have given their readers no information whatever as to the ages at which the deaths took place; nothing in the form of bills of mortality, nor any abstracts from them; they merely state that the data from which they formed the table of mortality they have given (p. 36), were carefully collected during three years from the civil registers of the kingdom.

A very valuable memoir, the result of more than two years' labour, entitled *Recherches Historiques et Statistiques sur la Population de Genève, son mouvement annuel et sa longévité, depuis le 16^{me} siècle jusqu'à nos jours* (1549—1833), by M. Edouard Mallet, was read to the *Société de Physique et d'Histoire Naturelle* of that city on the 18th of November 1834. It is divided into three parts; the first contains all that is known of the population of Geneva, and the successive enumerations of its inhabitants from the sixteenth century to the present time, with some details respecting the extent of the place, its habitations, its climate, and the industry of its inhabitants. The second exhibits the progress of the population from the commencement of the registers in Geneva, in December 1549, to the restoration of the republic at the end of December 1833, a period of 164 years, especially the meritorious but hitherto unpublished labours of Drs. Cramer and Joly; the progress of the population is given year by year, viz. for the deaths from 1549, for the marriages and births from 1693; and some theoretical inferences are drawn respecting the different elements of this population, the continual increase of its longevity and decrease of its fecundity. The third part presents the detailed results of the progress of population in Geneva during the twenty years 1814—1833, from the restoration to the end of the latter year. The necessary length of this memoir prevented the whole of it being published in the second part of the seventh volume of those above mentioned; he therefore gave in that place the third

part of it only, but not even that without omitting an explanation of the steps he took in making, himself, extracts from the registers, to render them available for useful purposes. This third part being the result of his own labour, and containing new facts and discussions relative to the progress of the population during that term of twenty years, 1814—1833.

The above is nearly a literal translation of the short preface to that part; although read to the society in November 1834, it was not published till the end of the year 1836; and the whole of the memoir, including what was omitted in the first publication of the third part was inserted in the *Annales d'Hygiène Publique*, No. 33, (being tome xvii. *prem. partie*.) which appeared in January 1837.

M. Mallet shews, that at a remote period the legislature of Geneva considered an exact knowledge of the population of the city a matter of importance, and he has given it at nine different periods of enumeration; the first in the year 1589, when it was 13,000, the last in 1834, when it was 27,177, of whom 12,573 were males and 14,604 females; at the same time the population of the suburbs was 9052. In these enumerations the administration took no account of the numbers of locations or of families, nor of the proportions of the people in the states of celibacy, marriage or widowhood; neither do they appear to have taken any account of the ages of the people at any of the enumerations, which is much to be regretted, as that information would have greatly enhanced the value both of the enumerations and of the extracts from the registers of births, deaths and marriages; it would have enabled us to determine the law of mortality in Geneva, which has not yet been done, although repeatedly attempted and thought to have been effected satisfactorily.

The deaths are certified by a visiting surgeon, who gives an account of them every week to the hospital where the civil registers are kept; and it is from his statements that the general mortuary registers are formed. The births, marriages and deaths that take place in the suburbs are entered in the registers with those of the city till 1791 for the marriages and births, and till 1805 for the deaths. Since 1799 for the marriages, and since 1806 for the births and deaths, those only for the population of Geneva within the walls are stated. The population of the suburbs has seldom been ascertained or stated with that of the city. In the registers of births and deaths the sexes are always distinguished; the abortive and still-born are stated separately; but before the year 1814, at which period M. Mallet took up the bills twenty years afterwards, as in too many other bills of mortality, they were also added to the number of deaths, properly so called, which took place among the living, and were therefore likely to be included among them by incautious or unskilful persons in calculating the rate of mortality.

The mortuary registers of Geneva, as M. Mallet remarks, have been the object of a great and laborious work, which the celebrated economist M. D'Ivernois has lately discovered by chance.¹ This work, the fruit of immense researches in the old registers, for a period reaching so far back as the

Mortality,
Bills of.

¹ The author of this article happened accidentally to contribute to this. In his letter of the 20th March 1834, to Sir Francis D'Ivernois, he requested information respecting the extracts from the mortuary registers of Geneva made by the late Dr. Cramer, which M. Duvillard, in his work on small-pox and vaccination, stated were communicated to him by Dr. Butini; also respecting the labours and publications of Dr. Odier, and others there mentioned, p. 105. In answer, M. D'Ivernois was so obliging as to favour him with three letters dated respectively the 2d and 16th of April, and the 17th of May of that year, with satisfactory information as to where the publications of Dr. Odier on the subject are to be found. In the first is the following passage: "Quant aux ouvrages, ou plutôt aux notes du Dr. Cramer ce n'étaient que des notes manuscrites qu'il laissa à sa mort à son ami le Dr. Butini lequel les communiqua dans le temps à M. Duvillard." In the second; "J'en profite aussi pour vous remercier d'une découverte bien précieuse que vous m'avez fait faire en me demandant les ouvrages du Dr. Cramer, son petit neveu le C. Cramer, vient de découvrir dans les papiers de famille un manuscrit qui est sûrement sans parallèle nulle part, rien moins que près de 200 tables de mortalité tenues année par année, et avec une exactitude remarquable pour Genève ville depuis l'origine de nos registers jusqu'en 1768." The third was accompanied by a printed half-sheet, in 8vo, being *Proposition de M. D'Ivernois, lu au Conseil Représentatif dans la s'once du lundi 12 Mai 1834*, in which he mentions the results of Dr. Cramer's labours as "consigné dans un manuscrit qu'un heureux hazard m'a fait découvrir depuis quelques semaines seulement." That third letter commences thus:

Mortality, Bills of. year 1549, and which, from 1560, when their representation of the progress of the population became regular, to the year 1760, contains no less than 15,777 deaths classed according to the ages at which they happened, was performed by Dr. Jean-Antoine Cramer. Periodical recapitulations and general tables give the results to the year 1760; Dr. Cramer continued the bills of mortality from that year till his death in 1775, and left then a continuation of them to the year 1770 inclusive. It was only from the year 1560 that the ages of the deceased were stated in the registers, and they were omitted during the twelve years 1568-1579, as were also those of 1648 individuals who died of the plague in 1615 and 1616.

Dr. Abraham Joly continued the inquiries of Dr. Cramer in the same manner during forty-one years, 1771-1811, and died himself in 1812.

Dr. Louis Odier published, in the *Journal de Genève*, for 9th July 1791, and in the *Bibliothèque Britannique*, for 1797, a *General view of the Mortality at Geneva*, which is nothing more than an abridged reproduction of Dr. Cramer's tables, but unfortunately left it to be inferred that they were the results of his own labours, and that was the impression produced.

But the most important work of M. Odier was a continuation of the labours of M. Cramer for the last forty years, 1761-1800, of the last century, and the first thirteen (1801-1813) of the present.

The other authors who have laboured in the same field of research, besides M. Mallet himself, are MM. De Candolle-Boissier, Serre, Dr. H. Lombard, M. Heyer.

Among many other useful and interesting tables, M. Mallet gives one which shews the progress of the population by giving the number of births, marriages, and deaths for each year, from 1549 to 1813, both inclusive, in the second part of his work; those for the next following period of twenty years in the third part.

We have here given a very imperfect account of this able memoir, which we consider highly creditable to the author's judgment and taste; almost all we have taken from it here is nearly literal translation, as we felt that we could hardly do otherwise without doing worse. Those who take interest in the subject will no doubt refer to the original, which, by being printed in the *Annales de Hygiène*, is easily accessible. We had gotten together the materials for a more lengthened notice of the labours of M. Odier, gathered from the *Bibliothèque Britannique*, but the opportune appearance of M. Mallet's memoir induces us rather to refer to it.

In M. Mallet's account of his own inquiries into the state of the population and mortality during the twenty years 1814-1833, we have the fullest information on every point, in the same manner and to the same extent for Geneva, as it has been given for Paris, in the *Recherches Statistiques*; but whilst these are generally confined to mere tabular statements of numbers and their proportions, with a few observations on them as can well be avoided; M. Mallet accompanies his tables with observations, reasonings, references to other authors, and the results of calculations very clearly stated, that greatly increase their value. As instances of the way in which he shows the uses of his tables, and assists his readers in drawing inferences from them, which will become much more interesting and instructive

by being compared with those drawn in the same way from Mortality, other tables of a similar kind; we give the two following Bills of. statements: after a table showing the numbers of births of males and females separately, in each of the twenty years, and for the whole term; also distinguishing the legitimate from the illegitimate, he gives the following

Proportion of the sexes.

Boys...	5678	— 51·9725	— 100	— 108·21	— 13.
Girls...	5247	— 48·0275	— 92·39	— 100	— 12.
	10·925	100·0000			

M. Mallet justly observes, that the proportion of boys to girls in the births at Geneva, is high in comparison with other places, and higher there in the present than in the last century, when M. Cramer estimated it to be 18:17; whilst in France since the restoration, it has been 17:16. He also states, that "M. Poisson a fait remarquer qu'il y a dans la proportion des sexes une différence notable entre les enfans légitimes et les naturels: chez ceux-ci, les naissances des filles se rapprochent plus de celles des garçons que chez ceux-la. M. le Professor Prévost a même donné une explication, si non tout-à-fait satisfaisante, du moins très-ingénieuse de ce phénomène. La plus grande proportion des mâles dans les naissances légitimes n'est nulle part plus frappante qu'à Genève. En effet, on trouve:

Legitimate	Boys...	5128	— 52·151	— 100	— 108·99
	Girls...	4705	— 47·849	— 91·75	— 100
		9833	100·000		
Illegitimate	Boys...	550	— 50·366	— 100	— 101·48
	Girls...	542	— 49·634	— 98·54	— 100
		1092	100·000		

M. Mourgue, however, had stated the numbers of births of both sexes separately, with distinction of the legitimate from the illegitimate, in the first part of his valuable memoir on the progress of population in Montpellier, published in the *Mem. de la Soc. Roy. de Médecine*, ann 1780 et 1781; and the whole of the memoir was read at a meeting of the French National Institute as above mentioned in 1795; but he made no remark on the difference in the proportion of the sexes between the legitimate and illegitimate births. Mr. Milne in his *Treatise on Annuities*, published in 1815, (article 789) has stated the proportion of the sexes at birth for several places at different times and under various circumstances; with distinction of the legitimate from the illegitimate in Sweden and Finland, and in Montpellier; he also there expressed his opinion, confirmed by subsequent observations, that the difference depends principally upon the age of the parents; the younger the parents, the nearer the proportion of the numbers of their male and female children at birth approaching to equality. What the connexion is, between the cause and effect, is a curious and interesting problem, which has not yet been solved that we are aware of.

In Wales the pressure of the population upon the means of subsistence in a way suited to the wants and habits of the people, is such as, notwithstanding their great disparity in civilization and refinement, to produce great similarity

"Voici un discours dont je vous dois l'hommage car la première idée m'en est venue à la suite des renseignements que vous m'aviez demandés sur le Dr. Cramer, et qui m'ont fait découvrir dans la poussière d'une grenier le recueil non interrompu de 200 tables de mortalité pour Genève. Il m'a paru mériter d'être mis en évidence. Mais voilà tout ce que je puis vous envoyer des œuvres de ce modeste écrivain."

We perfectly agree with M. Mallet in the opinion expressed by him in a note supporting it, from which the following is extracted: "Le travail de M. Cramer a été attribué à M. Odier par divers auteurs, MM. Prévost, Serre, D'Ivernois, Lombard. Pour rendre à chacun ce qui lui est dû, je dois dire qu'il est démontré à mes yeux, que le relevé mortuaire de 1560 à 1760, appartient en propre à M. Cramer. Le beau manuscrit qui le renferme est tout entier de la main de M. Cramer, comme je m'en suis assuré en le comparant à la signature du docteur, dans la registre de la faculté de médecine de Genève. A l'époque où s'arrête les tables de recapitulation de M. Cramer en 1760, M. Odier n'avait encore que 12 ans."

Mortality, Bills of. between the inhabitants of the principality and those of Geneva *intra muros*, in the proportion of the annual marriages to the population, and of the sexes at birth; which M. Mallet appears not to have been aware of. Whence we infer a similar resemblance in the advanced age of marriage, and the small average number of children to a marriage (in Geneva during these 20 years $2\frac{1}{2}$); the very defective state of the British registers of births rendering them of no use in this inquiry, except in determining the proportion of the sexes at birth, for which they may be used, as, however defective these registers may be, there is no reason to suppose they are more so for one sex than the other.

In Wales.		
During the years.	No. of persons to one annual marriage.	No. of males born for every 100 females.
1811 — 1820	141·636	109·500

1811 — 1830	142·334	110·207
In Geneva.		
1814 — 1833	141·593	108·990
In England.		
1811 — 1830	121·342	104·277

Dr. Casper's *Contribution to Medical Statistics*,¹ was published at Berlin in 8vo in 1825; it is divided into three parts: the first treats of suicide and its increase in our time; the second, of the poor and of the sick poor in Paris; the third, of the mortality among children in Berlin. The last part contains a variety of tables shewing the numbers of births in different years, distinguishing the legitimate from the illegitimate, and of the deaths that took place among them under fifteen years of age. The numbers of deaths by small pox, and a few other diseases of children, (but not each of those others separately,) both before and after the introduction of vaccination, are given; but no mention is made of their ages, and we need not notice them farther here.

A second volume by the same author was published at Berlin in 8vo in 1835 with two title pages, one being the same as that of the work above mentioned, published ten years before, with the addition of "vol. ii.;" the other, *An Inquiry into the probable Duration of Human Life amongst different classes of the people*.²

The second volume contains a great many tables in the text, and seventeen at the end; most of them copied from other works, but some that appear to be original; of which, those most material to notice here, are, 1st. The number of deaths in every year of age, from birth to 104 years completed, of males and females separately, which took place in Berlin during the twelve years 1818–1829, amounting to 36,895 males, and 32,467 females, of both sexes 69,362; these are given in his table of mortality for Berlin at the end of the work, numbered II. 2d. A table given in the text, (p. 106), showing the number of deaths that took place in Hamburg during the seven years 1819–1825, without distinction of sex, in the first and second years of age separately, then those between 2 and 5 and between 5 and 10; after that in every decade of age from 10 to 90, and those above 90 years of age. But the numbers of the

people in the different intervals of age not being given in either of those cases, any tables of mortality constructed from the numbers of deaths alone, at the different ages, can be of no value.

In vol. i. part 1, of *The Transactions of the Statistical Society of London*, recently published, there is *A statistical view of the births and deaths in the Prussian States, during the fifteen years 1820–1834*, translated from the German of M. Hoffman, Director of the Statistical Bureau in Berlin, the numbers of births and deaths, with distinction of the sexes, and the mean number of the people without that distinction during that term of fifteen years are given; also the number of deaths during the same term, with distinction of the sexes, between birth and one year of age completed, between 1 and 3, 3 and 5, 5 and 7, 7 and 10, and then in each quinquennial interval of age to 90, and those above 90. But the intervals of age into which the people were distributed in the Prussian enumerations appear never to have been sufficiently minute to admit of their being available for determining the law of mortality. There is a good deal of interesting information in this paper; but the above is all we can with propriety notice here; especially as the translation must be easily accessible to most of our readers; and throughout this article it has been our object to give the most minute accounts of such interesting publications as, to many readers, may be difficult of access; that those who take interest in them may see whether it may be worth their while to procure the perusal of them; and also to assist others in perfecting similar labours which they may be engaged in.

In the first volume (which is statistical) of the work of the Baron of Sedlitz, *On the power of the Prussian Monarchy under Frederic William III.*³ there is given (p. 284) for each of the seven years 1816–1822, including the military but excluding the inhabitants of Neufchatel, the number of inhabitants of the kingdom, the number of marriages, the whole number of births, and the number of illegitimate births separately, also the number of deaths; but without distinction of age or sex. He also gives the number of inhabitants for two of these years under 14 years of age, between 14 and 60, and above 60, which, however, are included in the statistical view of M. Hoffman.

One of the best bills of mortality we have seen, is prepared by the Board of Health at Hamburg, and published under the name of a Table of Mortality, covering all the four sides of a large folio sheet; and consist in fact of five tables regularly numbered.

I. The first shows the total number of interments and the daily average number, also the total number that took place at each of fifteen different burying places, during each month of the year separately, and during the whole year; without distinction of age or sex.

II. The second shows the same during each month for the abortive and still-born separately; then the deaths properly so called, which took place amongst the living, during each of the four quarters of the first year of age, in the second year, between the ages of 2 and 5, and of 5 and 10 years, then in each decade of age to 100, and those above 100; with the total for each month and for the whole year, of each sex separately, and for both sexes without distinction. There is also a column set apart for those whose ages were not known.

III. The third table consists of two parts, both of which are abstracts from the second; the first showing for each month the number of the abortive and still-born, and also of the deaths under and above ten years of age. The second,

¹ Beiträge zur medicinischen Statistik und staatsarzneikunde.

² Die wahrscheinliche Lebensdauer des Menschen, in den verschiedenen bürgerlichen und geselligen verhältnissen, nach ihren bedingungen und hemmnissen untersucht vom Dr. J. L. Casper.

³ Die Staatskräfte der Preussischen Monarchie unter Friedrich Wilhelm III. 1ster band. Berlin, 8vo, 1828.

Mortality,
Bills of.

besides the number of abortive and still-born, shows the number of deaths in each of the above-mentioned intervals of age. The sexes are distinguished throughout.

IV. The fourth table, besides the abortive and still-born, shows the number of deaths of each sex, and of both without distinction, that took place within the year, both under and above ten years of age, by about eighty different causes, besides those by suicide in various ways, and other violent deaths.

V. The fifth table shows the number of children born in each month of the year, and during the whole year, both alive and dead at birth, with distinction of the sexes of those born alive, but not of the others; that, however, is given for them both in the 2d and 3d tables; the number of twin and triple births are also stated in separate columns.

The only fault we see in this bill of mortality, which, in other respects, may well serve as a pattern for others, is the most improper practice of including the abortive and still-born children in the totals both of the births and the deaths; they should always be stated, but kept separate, both from those born alive, and from the deaths that took place among the living. The distinction of the legitimate from the illegitimate births with that of their sexes, would also be an improvement, if it could well be made; but we consider it to be much more curious than useful. The author is only in possession of one of these Hamburg bills, which is for the year 1836. The totals were as follow:

Births.	Males.	Females.	Both sexes.
Abortive and prematurely still-born ¹	85	56	141
Still-born at the full time...	96	81	177
Totals.....	181	137	318
Born alive.....	2109	1951	4060
Deaths.....	2138	1837	3975

No attentive reader can fail to be struck with the difference (so ill understood) in the proportion of the sexes among the three kinds of births; those born alive, the still-born, and the abortions. This bill is but for a single year, but the same kind of difference prevails generally; and can hardly be contemplated by a philosophical mind without exciting curiosity and the desire of further information as to the difference between the sexes, first, in the difficulty of fully entering upon life, and afterwards in retaining it, more strongly marked, as we approach nearer to the period of conception.

In October 1836 appeared, in the 32d number of *Annales d'Hygiène* (tome xvi. part 2), *Considérations Statistiques sur le Royaume de Naples*, addressed to the Royal Institute of France by Dr. Salvatore de Renzi, in which he shews why the population of the kingdom, and consequently the rate of mortality among the people, could not be determined previous to the year 1818. He gives four tables. The first shews for each of the sixteen years 1818-1833, the number of the people, and the numbers of births and deaths which took place among them, in each of the fifteen provinces of the kingdom separately, without distinction of the sexes, and without including Sicily, being able, he states, to assure his readers of their exactness and precision during that period being incontestible.

The number of inhabitants in 1818 was 4,990,380, and at the end of 1833 it was 5,883,273. In his second table, he gives for each of the provinces, and for the whole of the kingdom, the proportions of the annual average numbers of births and of deaths to the number of the people. The following are a few of them:—

Province.	No. of inhabitants out of which one	
	was born annually.	died annually.
Capitanata,.....	M. 21	26
Principato citra,.....	m. 29	m. 48

— ultra, 2°,.....	28	43
— citra,.....	24	M. 21
The whole kingdom,....	25	36

Mortality,
Bills of.

M. set against a number denotes that the mortality or fecundity is there a *maximum*, and m. that it is a *minimum*, not of those above mentioned only, but of all the provinces in the kingdom. The third table shews in what proportions 1000 inhabitants, and the fourth in what proportions 1000 deaths were, in each province separately, and in the whole kingdom taken together, distributed into the following intervals of age:—between birth and one year completed, between 1 and 8, 8 and 19, 19 and 26, 26 and 41, and those above 41 years of age.

A bill of mortality is published annually for the city of Naples, which contains most of the information contained in other bills of that kind; but is defective in one important point, the statement of the ages at which the deaths took place, those of the inhabitants are not even mentioned, which indeed is too common elsewhere. It states the number of the people at the end of the year it reports upon, and also at the end of the preceding year. The sexes are always distinguished in the enumerations of the people, as well as in the births and deaths; the legitimate are also distinguished from the illegitimate births; the number of twin births, with the sexes, are stated, and how many of them were pairs of boys, how many of girls, also how many of the pairs were children of different sexes; as was also done by M. Mallet and M. Hoffman, in their statements for Geneva and the Prussian states respectively.

The numbers of immigrants into and emigrants from the city, are stated, distinguishing native Neapolitan subjects from those of foreign states; the number of marriages contracted is given, but without any information as to the ages or previous conditions of the contracting parties. The number of deaths at home, and those in the hospitals and other public establishments are stated separately. The proportions also are always stated: as of the births, deaths, and marriages to the population, and of the annual births to the contemporaneous annual marriages, but not minutely; they are expressed in vulgar fractions, instead of decimals, having always the same denominator, as 100 or 1000, which is a great fault. No information is given as to the ages of the people, and the deaths are only stated in the following intervals of age:—between birth and 1 year completed, between 1 and 11, between 11 and 18, 18 and 26, 26 and 41, and those above 41. The only bill for the city of Naples in the author's possession is for the year 1822; it was inserted in the *Giornale del Regno delle due Sicilie*, of the 8th of February 1823. The population at the end of 1822 was 344,716, of whom 163,059 were males, and 181,657 females; at the end of 1821 the number of inhabitants was 341,143. The total number of births in 1822 was 14,233; of deaths, 12,195. The number of deaths in 1822 at ages above 100 years, was 17, and of the deceased 6 were males, and 11 females; the names, residences, and ages of them all are stated; they were all citizens of Naples but three, who came respectively from Procida, Salerno, and Venice, which last, Rosa Romanzo, was the oldest of all, having at

¹ *Unzeitige und frühzeitige todteborne*, that is, untimely and early still-born, by which we presume are meant, the abortive which had never quickened, to use a more common than well defined term, and those which died between the time of quickening and the full period of gestation.

Mortality, Bills of. tained the age of 107; three other ladies attained each to the age of 104.

In the same Journal, for the 23d of April 1823, a bill of mortality for the city of Palermo during the year 1822, compiled by Dr. Francesco Calcagni, is given. The number of inhabitants at the end of 1821 is stated to have been 160,051, and at the end of 1822, 161,735; but this last was derived from the first number, only by adding to it the excess of the births above the deaths during the year 1822. No useful information is given as to the ages of the deceased, and this bill is in other respects inferior to that for Naples; it differs from that, and all others we have seen, in tracing persons born out of wedlock to their graves, whatever age they may attain, and distinguishing the legitimate from the illegitimate in the numbers of deaths as well as of births. In 1822 the number of deaths of the legitimate was 4476, of whom 2294 were males, and 2182 females; that of the bastards, as they are called, was 418, of whom 151 were males, and 267 females. Of the illegitimate children born in that particular year, 256 were boys, and 307 girls. Out of the 4894 deaths, 16 of the deceased are stated to have attained ages from 97 to 105 years; but no information is given as to the distribution of those 16 persons into or among those last nine years of age.

For these two Italian bills of mortality, the author is indebted to Mr. W. R. Hamilton, who was so good as to send them to him from Naples, when they were published; and he is happy to avail himself of this opportunity to acknowledge his obligations to that gentleman, for the facilities he has afforded him of procuring information from abroad on other occasions.

Of all the statements derived from bills of mortality and enumerations of the people, which we have mentioned, only those for Sweden and Finland, Dr. Heysham's for Carlisle, and Dr. Cleland's for Glasgow, have been given in the proper form, and with sufficient correctness to afford the information, which is the most important object of them all, viz., that which is necessary for determining the law of mortality.

To effect this, it is only necessary to know the mean number of the living and of the annual deaths, in sufficiently small intervals of age, throughout the extent of life, for a period of time sufficient to allow of the accidental fluctuations arising from more or less fruitful years, and other causes, compensating each other: such periods, probably, should not be less than eight or ten years; but the necessary length will depend upon the climate, the number of the people, their general modes of life, and their political circumstances.

These data being obtained, it is not difficult to determine the proportion of the annual deaths to the number of the living in each year of age. Then, assuming any number of births, as 1000 or 10,000, it is easy to show how many would die in each year of their age; and, consequently, how many would survive that year; which numbers of survivors and of annual deaths, when arranged in the order of the ages, constitute the desired table of mortality, by which all the most important questions respecting the duration of human life may be easily resolved.

For want of understanding the principles upon which the proper construction of such tables depends, most of the writers on this subject, many of them men of great merit and industry, have taken much pains to little purpose, and after excessive labour, have arrived at false conclusions. Hardly any of them appear to have been aware of the necessity of obtaining the number of the living, as well as of the annual deaths in each interval of age, or that that would greatly enhance the value of Bills of Mortality, by extending their useful applications.

Dr. Price's *Essays on the proper Method of constructing Tables of Mortality*, already mentioned in this article, was intended to show how such tables might be constructed

from registers of the *deaths only* at all ages; but the hypotheses he proceeded upon can hardly obtain in any real case; and even if they did, his method would only determine the number of the living in the place, at every age; therefore, if it could be put in practice (which it never can), it would only supersede the necessity of actual enumerations; and, with the numbers so obtained, we should have to proceed as above.

That *Essay* of Dr. Price was an amplification of what Mr. Simpson had previously advanced on the subject, with his accustomed accuracy, and contains many just observations on the defects of the tables of mortality that had previously been published; but so far as it contributed to induce a belief that the determination of the number of the living in every interval of age, by actual enumeration, was not necessary to the construction of accurate tables, it must have done harm.

What is here stated will be found demonstrated in the third chapter of Mr. Milne's *Treatise on Annuities*.

It is desirable that a bill should be published for each year separately, to show how the rates both of mortality and fecundity, vary with the circumstances of the people in different years; and, from these yearly bills, nothing is more easy than to derive others for longer periods.

According to the form A, the births of both sexes in each year will be distinguished, and the born alive from the still-born; the number of marriages will also be given.

In this, and all other cases where those who undertake the formation of such bills are either unable or unwilling to distinguish all the particulars indicated, the reasons for the omissions should be inserted in the spaces set apart for the numbers omitted. The number of still-born children should always be stated separately, and should never be included in the number either of the births or deaths with those who had lived and breathed.

The numbers of deaths of the two sexes in each interval of age, during any year, may, as they are collected from the registers, be conveniently disposed according to the form B; the intervals between five years of age and an hundred, being each five years; and the number dying at each age above an hundred should be particularly specified.

But some persons, who would not take the trouble of forming bills of mortality in which the ages are to be so minutely distinguished, might yet be willing to furnish them with the requisite care, according to the form b, which might still be very useful; and, indeed, from twenty to sixty years of age, intervals of ten years each might do very well.

The value of Bills of Mortality would be greatly enhanced, by inserting in them the contemporaneous wages of labourers in agriculture, and of the workmen employed in the more common kinds of trade and manufacture carried on among the people they relate to; also the prices of the necessaries of life which persons of these descriptions consume the most of; together with any thing uncommon in the seasons or the crops, and every material change in the circumstances of the people.

ENUMERATIONS.

The number of the people in the several intervals of age, which we have stated above to be of so much importance, may be disposed in tables exactly similar to B or b, recommended for the deaths; but it is not necessary that the duration of life should be divided into the same intervals for the living as the dead. It is always desirable that the intervals should, in both cases, be small; but yet not so small, as, by the increase of labour, to occasion the numbers being determined with less exactness, or to deter many from engaging in the work. Such intervals should not, however, exceed ten years.

When the bills are given for a certain period, if there be

Mortality, but one enumeration of the people, it should be made at the middle of the period; if two, at its extremities; and if more than two, it is desirable that they should be made at equal intervals of time throughout the period.

We give no forms here of Bills of Mortality and Fecundity, designed to distinguish legitimate from illegitimate children, or the mortality or fecundity of each month of the year, nor the number of women delivered annually at the different periods of life, nor the diseases the deaths were occasioned by. Neither are the forms here recommended for enumerations of the people, calculated to distinguish the numbers in the different states of childhood, celibacy, marriage, or widowhood; nor the ranks, or professions, or occupations of the people. All these things are curious, and of some use, although, if we except the diseases which the deaths of each sex at the different ages were occasioned by, they are of little value in comparison with the information the forms here given are calculated to convey. And it is of so much importance that that information should be given correctly, that we would willingly forego these minor objects, to avoid dividing and fatiguing the attention of those who undertake the more important part of the task, which is of itself sufficiently laborious.

And those who may be disposed to keep registers, and form bills and enumerations, on a scale so much extended as to include all these particulars, or most of them, and have also the requisite qualifications, will find no great difficulty in preparing the most convenient forms of tables for the purpose. Several forms of that description, with references to others, will be found in Mr. Milne's *Treatise on Annuities*, and in many other works referred to in this article.

Fem...	395	47									18	10	2			959
Both...	812	89									25	14	2			1840

The first, second, and fourth of the following tables are good examples of that kind; but for insertion of the deaths of children, we prefer the intervals of age between one and two, and between two and five, to those used in the Swedish tables, viz. between one and three, and between three and five; because the greatest mortality prevails at the earliest ages; and that from small-pox is greatest in the first year of age, while the mortality from measles is greatest in the second year. It is, therefore, desirable to have the means of comparing the rates of mortality in the first and second year of age in registers kept both before and after the prevalence of vaccination.

Information on the diseases and mortality of children is highly desirable; and as their ages at death can generally be stated correctly, if accurate registers were kept of the numbers born alive, and of the numbers of annual deaths at all ages, with the causes of them, the rate of mortality amongst children at every age might thence be determined, and even that produced by each of the principal diseases at each age. It will be seen by our account of the Parisian *Recherches Statistiques*, or by the *Annuaire du Bureau des Longitudes*, that the numbers of deaths of children are given for Paris in much more minute intervals of age than is usual in this country; and by the *Jaarboekje* of M. R. Lobatto, published at the Hague, that for Amsterdam, and also by the *Annuaire de l'Observatoire de Bruxelles*, by M. A. Quetelet, that for that city, they are given in intervals of age still more minute than for Paris. This indeed is the case for more advanced ages, but we consider it as being there of less importance.

The expression we have adopted of the interval of age in which any lives were prolonged, or in which any deaths took place, we consider as at once the most simple and free from ambiguity; yet it has been stated to be ambiguous, an opinion which we conceive can only be held by those who do not clearly comprehend the exact import of the expression. We therefore trust we shall be excused for giving an explanation here, of what we thought could have required none.

The age of every individual being the time that has elapsed since the moment of birth, is at that moment nothing; we therefore express it by 0; and whatever portion we assume for the unit of time, whether an hour, a day, week, month, or year, the age at the expiration of that time from birth will be exactly one such portion; and all individuals of a less age than that, may be properly stated to be between the ages of 0 and 1. Except in infancy, one year is generally taken for the unit of age; a man at the moment of the 25th anniversary of his birth, is precisely 25 years of age, and until the 26th anniversary, he is between the ages of 25 and 26, or, in other words, in his 26th year; although, it being sufficient for common purposes, he is usually stated to be 25 years of age till he attains 26. At the 30th anniversary of the moment of birth, he will be precisely 30 years of age, but cannot continue of that or any other age during any assignable portion of time, however small. So that at the moment a man is enumerated amongst the living, or dies, the probability of his being precisely of any one age that can be expressed by a whole number of years, is infinitely small; and he may always with the greatest strictness and propriety be stated to be between two such ages. Thus, in the case last mentioned, of a man who has attained the 25th anniversary of his birth but not the 30th, he may be properly stated to be between the ages of 25 and 30.

M. Leyonmark observes that "the mortality during the five years, 1806-1810, was greater than it is stated in this table, owing to the lists of those who died in the service during the war, not having been so accurately made out as they ought to have been."
In the table sent to the author, from which the above has been copied, the average number of each sex in each interval of age was given in years and tenth parts of a year; and that given here in each case is the nearest whole number, whether greater or less: the difference is obviously of no importance.

In the copy received by the writer of this article, the deaths from ardent spirits were put between the drowned and the other casualties; and the diseases were not arranged in the order in which they stand here.

TABLE IV.

Shewing the number of Persons who died in the Kingdom of Norway in each of the undermentioned intervals of age during the term of Nine years which commenced with 1824, and ended with 1833.

Between the ages of	Males.	Females.	Both sexes.
0 and 5	38,362	32,500	70,862
5 — 10	3,753	3,349	7,102
10 — 20	4,377	3,964	8,341
20 — 30	6,589	5,694	12,283
30 — 40	6,645	6,602	13,247
40 — 50	6,725	6,431	13,156
50 — 60	8,378	7,569	15,947
60 — 70	11,023	11,753	22,776
70 — 80	11,744	14,501	26,245
80 — 90	6,396	9,134	15,530
90 — 100	1,024	1,761	2,785
above 100	52	102	154
at all ages, ...	105,068	103,360	208,428
The numbers, in the same time and place, of children born alive, were.....	181,712	172,784	354,496
Stillborn,.....	11,438
Thus it appears that the excess of the number born alive above the number of deaths, was	76,644	69,424	146,068

II.—MORTALITY, LAW OF.

THE Law of Human Mortality is that which determines the proportion of the number of persons who die in any assigned period of life, or interval of age, out of a given number of persons who enter upon the same interval; and, consequently, the proportion of them who survive that interval.

Tables showing how many out of a great number of children, as 10,000, or 100,000, born alive, die in each year of their age; and, consequently, how many complete each year; exhibit this law through the whole extent of life, and are called *Tables of Mortality*.

This section is divided into three parts. In the *first*, we deliver the history of this branch of knowledge, with as much brevity as appears to be consistent with the chief object, which is that of conveying correct and useful information.

In the *second part*, we demonstrate the whole theory by common arithmetic.

In the *third part*, a new table of mortality is given, constructed on the principles previously explained; some observations are made on the comparative merits of the different tables that have been published; which were purposely omitted in the historical part, when the tables they relate to were mentioned, to avoid discouraging such readers as might not be previously acquainted with the theory; and the faults are explained, which render most of those tables really of no use, since others, more correct, have been constructed.

PART I.—History.

The first table of mortality was constructed by Dr. Halley, from the Mortuary Registers of Breslau, for five years

ending with 1691; and was inserted in his paper on the subject in the *Philosophical Transactions* for the year 1693, with many judicious observations on the useful purposes to which such tables may be applied.

No further information of this kind was communicated to the public, until William Kersseboom of the Hague published there three tracts on the subject (in 4to.) The first, dated March 1, 1738, was entitled, *Eerste Verhandeling tot een Proeve om te weeten de probable menigte des volks in de provincie van Hollandt en Westvrieslandt*. The second, dated May 15, 1742, *Tweede Verhandeling bevestigende de Proeve om te weeten de probable menigte des volks in de provincie van Hollandt en Westvrieslandt*; and the third, dated August 31, 1742, *Derde Verhandeling over de probable meenigte des volks in de provincie van Hollandt en Westvrieslandt*.

A good account of the first of these tracts has been given by Mr. Eames, in the *Philosophical Transactions* for 1738; and rather a meagre one of the other two, by Mr. Van Rixtel, in the same *Transactions* for 1743. It is therefore unnecessary to repeat here, any thing contained in those accounts; but as they give no satisfactory information concerning the construction of Mr. Kersseboom's table of mortality (which he called a *Table of Vitality*), it will be proper to supply so material a defect in this place.

In his first tract, the author informs us that he constructed his table from registers of many thousand life-annuitants, in Holland and West Friesland, which had been kept there from 125 to 130 years previous to the date of his publication; and showed how many of the nominees, or lives the annuities depended upon, were, at the time of their nomination, under one year old, between one and two, between two and three, and so on for all ages.

Mortality,
Law of.

An exact account was also kept of the age at which each life of every class failed; whence it clearly appeared, what degree of mortality prevailed at every age above one year. But because very few children were nominated at or near their birth, he could not, from these registers, determine the mortality under one year of age. He therefore had recourse to mortuary registers and other observations; from exact accounts of which he found, with sufficient certainty, as he says, that out of 28,000 born alive, 5500 died under one year. He also informs us, that, for this purpose, he made use of the observations of divers learned men in England and elsewhere, especially Major John Graunt's, upon the number of the people and the rate of mortality; and upon taking an average of the whole, he found it to differ but little from that just stated.

And this appears to be the only ground for the assertion made by most writers on this subject (probably copying from each other without having seen the original work), that Kersseboom's Table of Mortality was constructed from observations made upon annuitants in England as well as in Holland; also, that it was formed partly from observations made upon the inhabitants of some Dutch villages.

He first published his Table of Mortality in his second Tract, and in his third, he gave abstracts of the registers from which it was constructed. These were contained in twenty-nine tables, twenty-two of which were for the two sexes separately; in the rest the sexes were not distinguished; and the ages at which the lives failed were generally given to the exactness of half a year.

The numbers of lives, whose current year of age at the time of their nomination was given precisely in these tables, were,

Males separately.....	1843
Females separately.....	1769
Males and Females, without distinction of sex.....	1536
Total.....	5148

And none of these nominees were above twelve years of age at the time of their nomination.

These, however, are only specimens of M. Kersseboom's labours. He says there were so many lives in the registers, that he had not the courage to undertake extracting the necessary particulars for more than 50,000 of them; and in that, he was greatly assisted by his friend Thomas von Schaak. Of all the lives, not more than 1 of 120 was past 55 years of age at the time of nomination.

Nicholas Struyck, in his *Aanhangsel op de Gissengen over den staat van het Menschelyk Geslacht, en de Uitreekening der Lyfrenten*, published at Amsterdam in 1740, at the end of the quarto volume, commencing with his *Inleiding tot de Algemeene Geographie*, gave, from registers kept at Amsterdam for about thirty-five years, two tables of observations made upon the duration of the lives of 794 males, and 876 female annuitants separately; and two tables of mortality he had constructed from them for the two sexes; both beginning with five years of age. These two, taken together, differ but little from that of Dr. Halley; they represent the mortality to be considerably greater than Kersseboom's: having been constructed from so few observations, they are not entitled to much confidence, and appear to have been very little known or attended to.

This work of Struyck gave occasion to the publication, in the same year, of a small tract in quarto, by Kersseboom, entitled, *Eenige Anmerkingen op de Gissengen over den staat van het Menschelyk Geslacht, &c.* wherein he accused Struyck of plagiarism, with but too much appearance of justice.

Neither Kersseboom nor Struyck gave any information as to the manner in which they formed their tables of mor-

talidity from the observations on which they were grounded. M. Kersseboom informs us, that he submitted his table to Professor S'Gravesande, some years previous to its publication, and obtained his approbation of it for calculating the values of annuities on lives.

Mortality,
Law of.

In the year 1742, Mr. Thomas Simpson, in his *Doctrine of Annuities*, (see the article ANNUITIES) gave a table of mortality for London, being the same that had previously been constructed by Mr. Smart, at twenty-five and all the greater ages, but corrected at all ages under twenty-five years, on account of the greater number of strangers who settle in London under that age, which occasioned, till the commencement of the present century, a constant excess of the burials above the births. This correction Mr. Simpson made by comparing together the numbers of christenings and burials; and observing, by means of Dr. Halley's table, the porportion between the mortality in London and Breslaw above twenty-five years of age.

In 1746, M. Deparcieux published (at Paris in 4to,) his *Essai sur les Probabilités de la durée de la Vie Humaine*, in which he gave six new and valuable tables of mortality; one of them constructed from the lists of the nominees in the French Tontines, principally those of the years 1689 and 1696, and the rest from the mortuary registers of different religious houses; four of these showing the mortality that prevailed amongst the monks of different orders, and the fifth, that which obtained amongst the nuns in different convents of Paris. Those for the monks and nuns, with the exception of the tables of Struyck, mentioned above, were the first ever constructed for the two sexes separately.

The *Essay* of M. Deparcieux is written popularly, and with great perspicuity; he has given the most satisfactory accounts both of the *data* his tables were constructed from, and the manner of their construction.

In his thirteenth table, he included with the five tables of mortality of his own construction; that of Mr. Smart for London, as corrected by Mr. Simpson, Dr. Halley's, and M. Kersseboom's, together with the expectation of life at, or its average duration after each age, both according to his own and M. Kersseboom's table for annuitants, and for every fifth year of age according to each of the other tables; the fractional parts of a year being always expressed in months, and not in decimals.

Dr. Halley first, and Struyck after him, had given the *probable duration of life* after several ages, according to their respective tables, that is, the term at the expiration of which, the persons now living at any proposed age, will be reduced by death to one-half their present number.

But Deparcieux appears to have first given the *average duration of life* after any age, and showed how to calculate it correctly from tables of mortality. On account of the scarcity and value of M. Deparcieux's *Tables of Mortality*, Mr. Milne has reprinted them, with the expectations of life just mentioned, in his *Treatise on Annuities*, with a short account of their construction; it is therefore unnecessary to pursue the subject further here.

In 1760 M. Deparcieux published (at Paris in 4to) his *Addition à l'Essai sur les Probabilités de la durée de la Vie Humaine*, with five tables; three of them relating to life annuities deferred on a peculiar plan, we consider to be of no interest or value at this time: the two others are tables of mortality constructed from statements of the numbers of deaths that took place at different ages, without knowing the numbers of the living at the same periods of life. He obtained the data for the first of them from a clergyman on the frontiers of Normandy and Perche, whose accuracy in all he undertook, he could rely upon; and who gave him the names of the parishes from the registers of which he had extracted the information; but strictly enjoined him not to disclose his name in the event of his making use of

Mortality, the documents. In these the sexes were not distinguished. Law of.

The other table of mortality M. Deparcieux constructed from statements sent to him by M. Wargentin of the numbers of deaths of males and females separately, which took place in the different intervals of age in Sweden and Finland, during the three years 1754, 1755 and 1756. Those two tables have the same faults as others constructed from similarly defective data; and we consider them to be of no value.

M. Deparcieux states, (p. 28) that in 1744, he suggested to M. Aubert, the commissary who at that time prepared the Bills of Mortality for Paris, the expediency of distinguishing the sexes in the columns of births and deaths, which had not been done previously, but was in consequence of this commenced with the year 1745, and has been continued ever since, as we have already observed in our account of the Parisian *Recherches Statistiques*.

M. de Buffon, at the end of the second volume of his *Histoire Naturelle*, published in 1749, inserted a table of mortality that had been constructed by M. Dupré de Saint Maur, from the registers of twelve country parishes in France, and three parishes of Paris; which M. de Buffon informs his readers that he inserted in his work the more willingly, since these were the only kind of documents, or combinations of them, from which the probabilities of life among mankind in general, could be determined with any certainty. Yet this was a very faulty table, and the numbers of annual deaths were so injudiciously distributed, according to the ages, that it often represented the mortality in one year of age to be three or four times as great, and in some cases, six times as great, as in the next year. Some remarks of M. Kersseboom on this table may be seen in the *Philosophical Transactions* for 1753. M. de Saint Cyran corrected some of its most obvious errors, and inserted both the original and his corrected copy in his *Calcul des Rentes Viagères*. (Paris, 1779, in 4to.)

Mr. Simpson, in the *Supplement* to his *Doctrine of Annuities*, published in 1752, gave some further explanations of the corrections he had made in Mr. Smart's table of mortality for London; and made some very judicious observations on the difficulties that attend the construction of tables of mortality from the mortuary registers only, of large towns.

In the *Nouveaux Mém. de l'Acad. Roy. de Berlin* for the year 1760, there is a paper by the celebrated Euler, entitled *Recherches générales sur la Mortalité, et la Multiplication du Genre Humain*, wherein the subject is treated algebraically. He assumes that the population is not affected by migration, and that the annual births and deaths are always as the contemporaneous population; consequently, that the number of the people increases or decreases in geometrical progression. Then he gives several theorems exhibiting the relations that would obtain between the annual births and deaths and the population, and determines the law of mortality upon these hypotheses, but does not shew how it may be deduced from actual observations independent of hypotheses; neither does he undertake the construction of any table of mortality, but, by way of example, gives that of M. Kersseboom, with the changes of the numbers which become necessary, in consequence of his altering the radix from 1400 annual births to 1000.

Süssmilch took great pains in collecting the numbers of annual deaths in the different intervals of age, which he published in his *Göttliche Ordnung*; and four tables of mortality formed from these data are to be found in the same work; that in the second volume (§ 461), which has many imperfections, was formed by himself; the three others, being the 21st, 22d, and 23d, at the end of the third volume, were constructed by his commentator Baumann, according to the more correct method of Lambert.

The first edition of Dr. Price's *Observations on Rever-*
VOL. XV.

tionary Payments, appeared in 1771, containing his observations on the proper method of constructing tables of mortality from bills which shew the numbers dying annually at all ages, and three new tables of mortality constructed from the London, Norwich, and Northampton bills.

The second edition of the same work was published in 1772, and contained, in the *Supplement*, much interesting and valuable information which did not appear in the first, together with five new tables, intended to exhibit the law of mortality that obtained, 1st, in the district of Vaud, in Switzerland; 2d, in a country parish in Brandenburg; 3d, in the parish of Holy Cross, near Shrewsbury; 4th, at Vienna; 5th, at Berlin. The first formed from bills of mortality given in the *Mémoire* of M. Muret; and the 2d, 4th, and 5th, from those given by Süssmilch in his *Göttliche Ordnung*; the 3d was from the parish register only of Holy Cross. But we consider none of those tables as now of any value, on account of the defects in the data from which they were constructed.

At the end of the first volume of the work of J. H. Lambert, entitled, *Beiträge zum Gebrauche der Mathematik und deren Anwendung*, published at Berlin in 1765, 8vo, he gave a chapter on the certainty of inferences deduced from observations and experiments; and the example with which he concluded the illustration of his theory, was the deduction of the law of mortality in London from the bills of mortality there; by means of a curve, of which the absciss being proportional to the age, the corresponding ordinate was proportional to the number of survivors of the same age.

In the third volume of the same work, published in 1772, the ingenious author treated the subject at much greater length: x being the age, and y the corresponding ordinate to the curve of mortality for London, proportional to the number of survivors of that age out of a given number (10,000) born alive, he gave this equation to the curve,

$$y = 10,000 \left(\frac{96-x}{96} \right)^2 - 6176 \left(e^{-\frac{x}{13.682}} - e^{-\frac{x}{2.43114}} \right),$$

(e being the number of which unit is the hyperbolic logarithm), which determined the numbers in the table of mortality very near the truth, until 96 years of age, beyond which it was not intended to be used.

M. Lambert also constructed a table by which he intended to exhibit the law of mortality that prevails among mankind in general, from the 23d and 24th tables in the second volume of Süssmilch's *Göttliche Ordnung*, which gave the numbers of deaths, in the different intervals of age, in seventeen country parishes in the mark of Brandenburg, and from the London bills for thirty years; supposing, with Süssmilch, (*Gött. Ord.* t. i. § 34), that the country people are double the number of those residing in towns.

By an extract of a letter from M. Lambert to Gaeta and Fontana, given in their Italian translation of Demoivre's *Treatise on Life Annuities*, (*Discorso Preliminare*, part iii.), it appears, that all his attempts to find *à posteriori* an equation which should determine the relation between the age and the number of survivors in this last table, proved fruitless; the formulæ he arrived at having been either too long and intricate, or too incorrect. This is the less to be regretted, since there is no doubt that M. Lambert's table did not represent the true law of mortality, as he made no allowance for the effect of the increase of the people by procreation; and it is singular he did not see that that law might be correctly determined from the numbers of the living, and the annual deaths at all ages in Sweden and Finland, given in M. Wargentin's paper in the *Stockholm Transactions* for 1766, which paper he himself quotes.

Lambert appears to have first demonstrated clearly the principal properties of tables of mortality, in doing which he made use of the differential and integral calculus; but

Mortality,
Law of.

Mortality,
Law of.

as he could not determine the equation to the curve of mortality, that resource did not avail him much.

Flourencourt treated this subject algebraically in the third chapter of his *Political Arithmetic*,¹ where he gave a perspicuous view of it, as it had been previously treated by Euler and Lambert; but added nothing himself that was original, except three new tables of mortality; one for males, another for females, and a third for both sexes without distinction; deriving his data in each case from the *Göttliche Ordnung* of Süssmilch. He also gave a new copy of the table of mortality M. Deparcieux had constructed from the registers of the nominees in the French tontines; assuming 10,000 for the radix, and inserting the numbers under three years of age, nearly according to M. Kersseboom's table; this, however, does not differ materially from the original table of Deparcieux.

The fourth edition of Dr. Price's *Observations on Reverſionary Payments* was published in the year 1783, and contained new tables of mortality for Warrington and Chester, also for all Sweden and Finland, and for Stockholm separately, in which the sexes were distinguished. Those for the whole kingdom were constructed from enumerations of the living, and registers of the annual deaths, in each interval of age, during twenty-one years; those for Stockholm during nine years. The tables for Sweden and Stockholm were the first ever constructed from the data that are requisite to determine the law of mortality among the bulk of the people, and were sufficiently accurate representations of that law, for the times and places in which the observations were made.

In a paper of M. Henrich Nicander, inserted in the *Transactions of the Royal Academy of Sciences* at Stockholm, for the first quarter of the year 1801, he gave two tables of mortality for all Sweden and Finland, in which the sexes were distinguished, but they were not properly constructed; and the mean duration of life which he gave in them at each age, was very erroneous, especially in early life. In that paper he asserted, without offering any demonstration or proof, that, in what we have called the curve of mortality above, if an ordinate be drawn through the centre of gravity of the portion of the area cut off by the ordinate at any assigned age, on the side of the more advanced ages, the part of the base, or of the axe of the abscisses, intercepted between these two ordinates, will measure the mean duration of life after such assigned age. And the mean duration of life after each age, which he has given, was determined in this manner.

Mr. Milne's *Treatise on Annuities and Assurances* was published in the year 1815; and, in the third chapter of that work, the construction and properties of tables of mortality are fully treated of.

In the second volume of the same work, three new tables of mortality are given; one constructed from very accurate observations made at Carlisle, by Dr. Heysham, who preserved the bills of mortality of the two parishes, which include that city and its environs, and supplied their deficiencies with great care, together with correct accounts of two enumerations of the inhabitants, in which their ages were taken; and a table showing the diseases by which the deaths at all ages were occasioned, is also given.

The fourth and fifth tables in Mr. Milne's work, exhibit the law of mortality which prevailed in all Sweden and Finland, both with and without distinction of the sexes, deduced from the registers kept and the enumerations made there, during the twenty years ended with 1795; which term was subsequent to that wherein the observations were made, from which Dr. Price's tables were constructed.

The seventh table in the same work exhibits the law of mortality at Montpellier for males and females separately, and was constructed from the bills of mortality of that place for twenty-one years, ending with 1792.

The second table at the end of this article, was published in the first edition of it in 1822; the tables of mortality for the lives insured in the Equitable Office, which were constructed by Mr. Babbage and Mr. Davies, were published in 1826; and we have given some account of them as well as of those formed by Mr. Finlaison, from observations on Government Annuities in this country, and published in 1829, in the article *Annuities* in this work.

MM. Quetelet and Edouard Smits, in their *Recherches sur la Reproduction et la Mortalité de l'Homme*, in 1832, gave a table of mortality for the towns and the rural districts in Belgium separately, distinguishing males from females, and also for the whole population, without distinguishing the sexes, or the inhabitants of towns from those of the country.

Mr. Morgan, in the above mentioned publication of the Equitable Assurance Society, in 1834, gave a table of mortality for the lives insured in it, (marked C, p. 28), derived from table A of that work; another (D) derived from table B, is not worth a place there.

The second of the tables at the end of Dr. Casper's work on the *Probabilities of Human Life*, published in 1835, was intended to exhibit the law of mortality in Berlin, with distinction of the sexes; it was constructed from 69,362 deaths at different ages; 36,895 of males, and 32,467 of females, which took place there during the twelve years 1818–1829. And M. Mallet at the end of his valuable *Mémoire*, published in 1836, has given one for Geneva, in which the sexes are distinguished: it contains both the mean and the probable duration of life after every age, and was formed from the bills of mortality there for the eighteen years 1814–1833. For males, females, and the two sexes without distinction, M. Mallet took so high a radix as 100,000 births; the number of deaths were, of males 5219, females 5688, of both sexes 10,907; and in the column of deaths, on the same line for any age, as the survivors of that age, the author has put the number of deaths in the registers in the next following year, instead of the decrement of life, or excess of the number attaining that above the number attaining the next greater age, which will probably puzzle many readers.

PART II.—On the Construction and Properties of Tables of Mortality.

1. Suppose 10,000 children to have been all born alive at the same instant of time, more than 100 years since; and that the numbers of them who completed and who died in each year of age, were correctly entered in the following table:

Age.	Number who	
	completed that year.	died in their next year.
0	10,000	1,888
1	8,112	453
2	7,659	256
3	7,403	177
4	7,226	130
5	7,096	112
⋮	⋮	⋮
90	49	15
91	34	11
92	23	9
93	14	5
94	9	4
95	5	2
96	3	1
97	2	1
98	1	1

Mortality,
Law of.

¹ *Abhandlungen aus der Juristischen und Politischen Rechenkunst*, von Carl Chassot de Florencourt. Altenburg, 1781, 4to.

Mortality
Law of.

which, then, would evidently be a table of mortality; and this mode of constructing one, were it practicable, would be the simplest possible.

2. But of 10,000 children taken indiscriminately at birth, it is manifest that the number who complete or survive any year of age, will be just the same, whether they be all born at the same time or not; and, therefore, this table might as well have been constructed by noting the times of the births of 10,000 children taken indiscriminately, and registering the time or the age at which each died; for then, after the whole were extinct, it would only be necessary to collect the sum of those who died in each year of their age, and insert it in the third column of the above table (1) against the proper age. The numbers in the second column would then be obtained by beginning with the 10,000 births, and merely subtracting the number in the third from the number in the second column, and placing the remainder in the next line below, in that second column, throughout the table.

3. It is evident that the number against any age in the second column of such a table, is equal to the sum of those in the third column against that, and all the greater ages; that is to say, that *the number who complete any year of age is equal to the sum of those who die at all the greater ages.*

4. Now let us suppose the population of a place to have remained invariable for one or two hundred years past, during which period 10,000 children have been born alive, at 10,000 equal intervals of time in each year. Also that, there having been no migration, and the law of mortality having been always the same, both the number of the living and that of the annual deaths in each year of age, have remained constant, the whole amount of the annual deaths at all ages, as well as the number of annual births, having been 10,000.

5. Then, if the law of mortality exhibited in the above table (1) be that which obtains in the place just mentioned, that table will represent the stream of life which flows through it, and fills the vacancies left by those who advance in age, or are carried off by death, their successors incessantly following and being followed in the same course.

6. Thus: 10,000 children being born annually at so many equal intervals of time, 7096 will annually complete their fifth year, also at equal intervals; and of these, 112 will die annually in the sixth year of their age.

7. And it is manifest that *the number who annually complete any year of their age in such a place, is equal to the sum of the annual deaths at all the greater ages.*

8. Let us next suppose, that the constant number of deaths which happen annually in any one year of age, take place at equal intervals of age in that year. For instance, that the four deaths which happen annually, in the ninety-fifth year of age, always takes place at the ages of

Years.	Months.
94	3
94	6
94	9

and 95 years; or rather, that the last individual dies at the moment before completing the 95th year.

9. Then the number constantly living in any year of age may be determined as follows:

Let us take, for example, the ninety-fourth year, which 14 persons annually enter upon, and 5 die in. Now, if no deaths happened in that year, it is obvious that the 14 persons who annually enter upon it at so many equal intervals (4 and 6), would be all constantly living at 14 equal intervals of age in that year; and if that year of age were divided into five equal intervals, there would be

constantly living in each interval $\frac{14}{5}$ persons; or, in a place

similarly circumstanced, but five times more populous, 14 persons.

But when five deaths take place at so many equal intervals in the ninety-fourth year of age, (the fifth part of a year being 73 days,) the case is altered. Thus,

Lives.	Complete the age of		Number of the living during these last 73 days.
	Years.	Days.	
14	93	73	$\frac{14}{5}$
13	93	146	$\frac{13}{5}$
12	93	219	$\frac{12}{5}$
11	93	292	$\frac{11}{5}$
10	94	...	$\frac{10}{5}$

Or rather, the oldest life that fails in the 94th year, must be considered to expire the moment before completing that year, as only 9 survive 94.

But the numerators of these fractions being in arithmetical progression, their sum is equal to half the sum of the first and last terms multiplied by the number of terms; or $\frac{14+10}{2} \times 5$; which sum being divided by the common denominator, 5, we have the number of the living in the

94th year of age $= \frac{14+10}{2}$; an arithmetical mean proportional between the numbers who enter upon the first and last of the intervals which that year of age was divided into.

10. Now, the number, 9, who survive their 94th year, is less only by unit than the number 10, who enter upon the last of the intervals that year was divided into; so that if, instead of $\frac{14+10}{2}$, we take $\frac{14+9}{2}$, or an arithmetical mean

proportional between the numbers who annually enter upon, and annually survive their 94th year, for the number constantly living in that year, it will only be less by half a life than what has just been demonstrated to be the true number, according to the hypotheses; and the difference would still have been but half a life, although the radix of the table had been 10,000,000 instead of 10,000; the number of the living would, in that case, according to these two methods, have been 1200 and 1199 $\frac{1}{2}$. And the number of the living in any one year of age, even according to the above table, is generally several thousands, so that this difference, which remains always the same, is quite immaterial.

Besides, it is obvious that the above hypotheses can never coincide exactly with the facts. And the above reasoning is evidently applicable to any other year of age.

11. We are therefore authorised to conclude, that in a place, circumstanced as above stated, *the number of the living in any year of their age is an arithmetical mean proportional between the numbers who annually enter upon, and who annually complete that year.*

12. Thus it appears that

The number of the living in their	Is half the sum of
94th year,	14 and 9,
95th —	9 — 5,
96th —	5 — 3,
97th —	3 — 2,
98th —	2 — 1,
99th —	1 — 0.

But it is to be observed, that the same numbers occur in

Mortality,
Law of.

Mortality,
Law of.

the first of these two series as in the second, except the first term of the first, and the last of the second, which are 14 and 0 respectively. Therefore the sum of the second of these two series falls short of the sum of the first by 14, the number who annually complete their 93d year; so that the series of half sums falls short of the sum of the first series by 7, the half of 14. And this reasoning will apply equally to any other age than that of 93 years.

13. Whence it follows, that in a place circumstanced as we have supposed, *the number of persons constantly living at any assigned age and upwards, is less than the sum of those who annually complete that and all the greater ages, by half the number who annually complete that year of their age.*

14. From the supposition that the number of persons who die annually in any one and the same year of age, expire at so many equal intervals of age in that year (8), it follows, that for each of these lives which fails before the middle of that year of age, there will be another which will fail just so much after it, and, consequently, that the average quantity of existence during any year of age, for the lives that fail in it, is just half a year.

15. But in taking, for any one year of age, the sum of the numbers in the second column of the table (1) at all the greater ages, each life is counted once for every complete year it survives, after the age first mentioned; and if, to the sum of these, we add half the number in the same second column against that first mentioned age, this half number being the sum of the fractional parts of a year, by which the whole of these lives survive the last year of age they complete (14); the sum total thus obtained will evidently be the whole duration of life after the age first mentioned, enjoyed by all the lives that survive that age in any one year.

16. Therefore, if this last sum total be divided by the number who annually survive that first mentioned age, the quotient will be *the mean duration of life after that age* which is also called *the expectation of life at the same age*, being the portion of future existence which an individual at that age may reasonably expect to enjoy.

17. But, by No. 13, it appears, that the last mentioned sum total is also the number constantly living in the place, at and above the age first mentioned (15).

18. Whence, and from No. 16, it follows, that if the number of the living in the place at any age and upwards, be divided by the number who annually complete that age, the quotient will be the mean duration of life after the same age.

19. And, consequently, if the number constantly living at all ages, be divided by the number of annual births, the quotient will be the mean duration of life from birth, or the expectation of life of a child just born.

20. Hence also it appears, that the number of years in the expectation of life at any age, is the same as the number of living persons at that age and upwards, out of which one dies annually.

21. Thus, for example, the expectation of life at 40 years of age being 25.495 years, the proportion of the living in the place aged 40 years and upwards who die annually, is one of 25.495, or, which is the same, 1000 out of 25,495.

22. The numbers represented by a table of mortality to die in any intervals of age, are called *the decrements of life* in those intervals.

23. And the interval between any age and the utmost extent of life, according to any table of mortality, is called *the complement of life* at that age, according to the same table.

24. If the decrements of life be supposed to be equal and uniform through its whole extent, and the interval between birth and the utmost extremity of life be divided into as many equal parts as there are annual births, then, one of the individuals born will die at the expiration of each of

these equal intervals of age; and the numbers who survive the several intervals, from birth to the extremity of life, will form an arithmetical progression.

25. Whence it will be found (11), that the number of the living at any assigned age and upwards, will be equal to the number who annually complete that age, multiplied by half the number of years in the complement of life at the same age.

26. And if this last product be divided by the number who annually complete that age, the quotient, that is, half *the complement of life, will be the expectation of life at that age* (18).

27. The mean numbers of annual deaths at all ages, or, which in this case is the same, the number of deaths in each year of age, that take place during any one year, in a place circumstanced as we have supposed, being given, a table may be constructed as follows, which will answer all the most interesting questions that can be put respecting the population and mortality of the place.

28. Let there be five columns, in the first of which insert the ages 0, 1, 2, 3, 4.....96, 97, 98, 99, and against every age, insert in the fifth column, the given number that died in the year between that and the next greater age; then begin at the greatest age, and proceed towards the least, as follows:—

1st, To the number against any age in the fourth column, add that against the next less age in the fifth, and insert the sum against that next less age in the fourth (7).

2d, To the sum of the numbers in the third and fourth columns against any age, add half the number in the fifth column against the next less age, and insert this last sum against that next less age in the third column (11).

3d, Divide the number against any age in the third column, by the number against the same age in the fourth, the quotient will be the expectation of life at that age, to be inserted in the second column (16).

A complete table of this kind for the two sexes separately, formed from observations made in all Sweden and Finland, during twenty years ending with 1795, will be found in Mr. Milne's *Treatise on Annuities and Assurances*, being the fourth in that work.

29. Hitherto we have supposed the state of the population to continue invariable for 100 years at the least, on account of the facility with which tables of mortality might be

Mortality,
Law of.

Mortality,
Law of.

formed from accurate mortuary registers in such circumstances.

But whether the population be stationary, or increasing, or decreasing, and from whatever causes these changes proceed, provided that they be produced gradually, and not by sudden starts during the time of the observations, the law of mortality may be determined from actual enumerations of the people, and the bills of mortality. Thus,

30. Let the number of persons in each year of their age, that are resident in a place at any one time, be taken, and let an accurate register be kept of the number that die annually in each year of their age, during a term of eight or ten years at the least, whereof the first half may precede, and the second follow the time of the enumeration.

Then, if the number of the inhabitants of every age either increase or decrease uniformly during that term, the mean number of annual deaths in each year of age thus registered, will be the same as if the population of the place had continued throughout that term what it was when the enumeration was made.

31. But if, to the number of the living in any year of age, we add half the number who annually die in the same year, the sum will be the number who annually enter upon that year of their age (11.)

And thus, from the enumerations and registers above mentioned, may be derived the ratio of the number who annually enter upon any year of their age, to the number who annually die in it.

32. But all the observations which have been made with sufficient minuteness, on the mortality during the first year from birth, concur in showing, that many more deaths take place in the first few weeks from birth, than in equal periods of time during the remainder of the first year; and that the nearer to birth, the greater is the mortality among infants. So that the number of the living in successive equal intervals in the first year of age, cannot be correctly assumed to be in arithmetical progression.

33. On this account it is desirable that the annual numbers, both of the children born alive, and the deaths under one year of age, should be correctly registered, as in Sweden.

34. Then, as the number annually born alive, is to the number of annual deaths under one year of age, according to the registers, so is the radix of the table of mortality, to the number dying under one year of age according to that table, which, being subtracted from the radix, the remainder is the number who complete their first and enter on their second year. Whence the numbers, both of survivors and annual deaths, at all the greater ages, may be determined in the order of their succession by No. 31.

35. If, instead of the number of the living in each year of age being taken only once, according to No. 30, that operation be performed several times during the term for which the mean number of annual deaths in each year of age is given;—then, the mean number of the living in each year of age throughout that term, must be deduced from the given numbers; and, being substituted for the number at the middle of the term according to No. 30, the law of mortality may be determined with more certainty, than when the people are only numbered once.

36. Both in enumerations of the people, and in bills of mortality, the numbers are, however, almost always given only for intervals of age of several years each. For the manner of interpolating the numbers in each particular year of age, the reader is referred to Mr. Milne's *Treatise on Annuities and Assurances*, arts. 180 and 181.

37. Hitherto we have only considered the determination of the law of mortality amongst the whole of the inhabitants of a place, of all ages, ranks, and conditions; and until within the last eight years, no statements of facts relating to particular classes of the people had been published, ex-

cept those of M. Deparcieux, in his valuable *Essai*, sufficiently numerous and correct to be available for the purpose. But the inquiries made by order, and with the aid of government in this country, into the mortality amongst various classes of nominees, on whose lives annuities depended, published in Mr. Finlaison's report to the Lords of the treasury in 1829, and already noticed in the article *ANNUITIES* in this work; with the publication in 1834, of the still more interesting, important, and distinctly detailed observations on the mortality that has taken place among the lives insured in the Equitable Assurance Society, form most valuable accessions to our knowledge of the subject; we therefore proceed to show how the law of mortality among those classes of persons may be deduced from these documents. We shall have compassed that object, when we have determined out of a considerable number of persons who entered upon each year of age, how many died in that year, and, consequently, how many survived it; and the Equitable Assurance documents are so disposed, as to afford great facility in effecting this. The following table is extracted from them, with the addition of the column marked B.

Mortality,
Law of.

A	B	Age 30.+			
		C	D	E	F
Age at admission.	Number admitted of that age.	Attained that age during the observations.	Of that age when they terminated.	Went out of the Society alive of that age.	Died of that age during the observations.

		4153		1078	

38. According to the common mode of expressing the ages, which is adopted both in the government documents

Mortality, and in those of the Assurance Society, the year of age stated is always that which was last completed; but where-
 Law of. ever that is the case, it should be distinctly stated, and kept steadily in view. We confine ourselves in this table to the 31st year of age, and mark it 30+, to avoid ambiguity; for the same reason (+) is put over the ages in column A, to show that each number in it denotes the age last completed.

39. Column B has been added for the sake of illustration; it shows at what earlier ages the different lives entered the society, which afterwards completed the 30th year of their age in it, and entered their 31st: thus, out of 40 insured in the 8th year of age during the period of the observations, only 5 entered their 31st while insured in the society, the rest having passed out of it either by death or otherwise, at earlier ages, as the preceding columns of the original table fully show; and of the 373 persons who were insured in their 22d year, 124 remained insured till they entered their 31.

40. This table shows that of 4692 persons who entered on their 31st year of age in the society, 265 went out of it alive in the same year of their age during the observations, 51 were still living and insured at the termination of the observations, and 762 came into the society in that year of their age; the individuals of those three classes amount together to 1078 persons. But of the 265 who went out of the society alive during that year of age, it may reasonably be assumed, that whatever number of them at the time of their exit exceeded 30½ years of age by any interval of time, as many would fall short of that middle age by the same interval, when they went out; and, therefore, that the whole of them on an average may properly be considered to have been exposed to the action of the Law of Mortality during one half of that year of age; so that the mortality among them must have been the same as it would have been among half the number of exactly similar lives, in passing through the whole of that year.

In the same manner it appears, that of the 762 persons who were insured at various periods of the 31st year of age, and of the 51 persons who remained alive and insured in the society at various periods of that year of age when the observations terminated; may, each of them on an average, be properly assumed to have been exposed to the action of the law of mortality in the society during one half of the 31st year of age; and we are therefore entitled to conclude that the mortality among them was the same as it would have been among half the number of exactly similar lives in passing through the whole of the 31st year of age.

But 4692, the total of the numbers in column C includes all those 1078 lives, the same as if they had all entered upon their 31st year of age in the society, and had all passed through it except those which were carried off by death. It is, therefore, manifest, that 539, the half of their number, must be subtracted from 4692, and the remainder, 4153 must be taken as the number of persons entering on the 31st year of their age, and continuing exposed to the law of mortality in the society during the whole of that year, among whom thirty-two deaths take place in the same year of age.

This, when the principle is clearly understood, is certainly a very simple operation and easily performed; and its application to every other age in the original table of data is exactly the same as to the 31st year.

41. In constructing the table of mortality, supposing that in proceeding from the earliest age we have arrived at the completion of the 30th year, or the entrance on the 31st, and have determined the number of survivors at that limit to be 4305; since

$$4153 : 32 :: 4305 : 33 \cdot 1712,$$

we find 33 to be the number of deaths which will take place in the 31st year of age out of 4305 persons who enter on it; and, consequently, that 4272 enter on their 32d year.

according to the table we are constructing; the method of completing it is obviously the same throughout, and can be attended with no difficulty after the valuable documents re-
 Law of. quisite for the purpose have been obtained.

42. What has been shown here respecting the determination of the law of mortality amongst insured lives, applies also, and with rather more facility to the nominees on whose lives annuities depend. The life annuities sold by government in this country not being redeemable, are always continued during the whole of the lives they depend upon; therefore, with regard to them, column E in the above table is left blank; and in the case of the old English Tontine, which commenced in 1693 and ended in 1783 with the life of the last survivor, column D will also be quite blank.

PART III.—On the Law of Mortality as deduced by the preceding methods from actual observations; and on the comparative merits of the different Tables of Mortality that have been published.

43. When the uniformity of anatomical structure in different individuals of the human species is considered, and the great power possessed by the human body, of so adapting itself to the circumstances it is placed in, as to avoid injury from changes in those circumstances, it appears natural to expect *a priori*, that, where the circumstances of the people are not greatly different, the law of mortality will be nearly the same. And, from a comparison of the best tables of mortality yet constructed, we are induced to believe that this expectation will be realized, whenever a sufficient number of good observations shall have been made, under circumstances sufficiently varied.

44. We know of no observations that have hitherto been made and published, from which the law of mortality may be correctly determined, except the following:

1. Those of M. Deparcieux in France.
2. The Swedish.
3. Dr. Heysham's at Carlisle.
4. Dr. Cleland's at Glasgow.
5. Mr. Finlaison's on the nominees of life annuities granted by government in this country.
6. Mr. Morgan's on the lives insured in the Equitable Assurance Society.

Those of Deparcieux, Finlaison and Morgan, were made only on select classes of the people; the Swedish are incomparably the most numerous and extensive; and whilst Dr. Cleland's exhibit the mortality in a large manufacturing town, Dr. Heysham's will, we believe, be found to be best authenticated, and most correct.

45. The climate of Sweden is so unfavourable to the products of agriculture, and the number of the people is so great in proportion to the quantity of food produced, that unfavourable seasons there, are generally followed by distressing dearths, and the destructive epidemical diseases constantly attendant upon famine, which raise the mortality, when they occur, much above what it would otherwise be; and both in that way, and by weakening the constitutions of those who survive them, they materially increase the average mortality deduced from observations made during any considerable number of years. Of this the reader will find ample proofs drawn from authentic sources, in the 10th, 12th, and 13th chapters of Mr. Milne's *Treatise on Annuities*.

46. For these reasons, the mortality in Sweden deduced from many years' observations, will be found to be higher than in the more temperate and fruitful parts of Europe. And we shall probably make the nearest approach to the general law of human mortality in the temperate climates, that can be made from the Swedish observations, by selecting a period in which no remarkable epidemics prevailed. Such a period was that of five years, 1801–1805; during

Mortality, which, according to a statement of M. Nicander, in the *Transactions of the Royal Academy of Sciences at Stockholm* for the year 1809, the population and mortality were as stated in Table I. at the end of this article.

47. From these *data*, the second table at the end of this article has been formed. The numbers in the columns for males and females separately, having been determined according to Nos. 36 and 31-35; assuming that, of 20,000 children born alive, 10,219 are males, and 9,781 females, in the ratio of 275,599 to 263,812.

The numbers against each age in the columns for the whole population without distinction of sex, are arithmetical mean proportionals between the corresponding numbers in the columns for males and females separately, against the same age.

48. From the table last mentioned, Table III. has been deduced by No. 16, exhibiting the expectation of life at every fifth year of age; or its mean duration *after* that age.

49. Vaccination commenced throughout Sweden and Finland in 1804, during which year, the number vaccinated was 38,255; and, in the year following, 42,839.

The number of deaths by small-pox there, during the year

1801, was	6,458
1802, —	2,679
1803, —	8,610
1804, —	3,764
1805, —	1,887
Sum,	23,398

Annual average number, 4,680

Whilst the annual average of the ten years ending with 1803, was 6962. (*Vet. Ac. Handl.* 1809, and Mr. Milne's *Treatise on Annuities*, art. 698.)

50. Therefore if we assume that, had vaccination not been practised in the years 1804 and 1805, the annual average number of deaths during the five years ending with that last mentioned, would have been greater by 2,282 than it actually was, and that these 2,282 additional deaths would have all taken place under five years of age, both assumptions will be near the truth; and it will follow that the annual mortality under five years of age, which actually was but one of 13,534, would have been one of 12,629, had vaccination not been introduced. Its introduction cannot have affected the first three tables above five years of age; and under that age, not quite so much as has just been stated.

51. Of all ages, and both sexes, there actually died annually, during these five years, one of 40,901; had vaccination not been practised at all, the annual average mortality would not have been so great as one of 39,759.

52. Table IV. exhibits the mean duration of life after every fifth year of age, according to twelve different tables of mortality; the first six, A, B, C, D, E, F, having been

constructed from the requisite *data* (30 and 38,) the last six, M, N, O, P, Q, R, from mortuary registers only.

53. The numbers in the first column A have been taken from table III. in Mr. Milne's *Treatise on Annuities*, and those in B from table E (p. 28) in the Equitable Assurance Society's publication.¹

54. Deparcieux's table C constructed from great numbers of accurate observations on the nominees in the French Tontines, resident principally in Paris and its environs, represents the duration of life too small after 60 or 65 years of age. (See Mr. Milne's *Treatise on Annuities*, articles 867 and 868.)

55. Column D has been taken from the 45th table in Dr. Price's *Observations*, E from the 5th in Mr. Milne's *Annuities*, and F from the 3d table in this article. All these tables represent the duration of life in Sweden and Finland, after 45 or 50 years of age, to be less than according to the others; and it might reasonably be expected, *a priori*, that the excessive cold in Sweden would be unfavourable to the prolongation of life in old age.

56. Of the less correct columns, M has been deduced from the 7th table in Mr. Milne's *Annuities*, and N from the 42d in Dr. Price's *Observations*; but, as the Montpellier and Chester tables, just referred to, give the expectations of life only for males and females separately, the numbers in columns M and N against each age, are arithmetical mean proportionals between the expectations for males and females against the same ages in those tables; which, though not quite correct, is fully sufficient for our present purpose.

57. The number in column O against each age has been derived from that given by M. Mallet in his table of mortality as the mean duration of life in Geneva from and after that age, by subtracting one half (0.5) from each of them; which will be found to be a necessary correction.

58. Column P has been derived from Lambert's table for mankind in general, already mentioned in the historical part of this article, in which he gives a column headed *mean age*. Thus, against the age of 20 in that column, stands 54.3, by which he means that persons who survive 20 years of age, do, on an average, attain the age of 54.3 years; so that their expectation of life at 20, will be 34.3. But his numbers in that column are all too great by $\frac{1}{2}$, or 0.5, as he has himself demonstrated; the last, therefore, should be 33.8; and

Against the age of	For his number.	We insert in column P.
0	29.5	29.00
5	47.7	42.20
10	51.4	40.90
15	53.1	37.60
	and so on.	

¹ The author of this article in reading the note on the 4th and 5th pages of Mr. Arthur Morgan's introduction to the valuable work above mentioned, when that gentleman was so good as to send it to him on its first publication, had noted with a pencil in the margin, that the practice there stated was not quite correct; but the circumstance had long passed from his recollection, when he showed in No. 40 of the present article, how the law of Mortality in the Society might be determined from the large and valuable table marked A; therefore, by the words "age on admission," at the head of the extreme left hand column over the age in the same horizontal line with the number of lives admitted in the first division of the large column with that age at its head, he was naturally led to conclude that that was, as it ought to be, the number of lives which really were insured during the observations, when that was the age they had last completed. But by the note referred to, it appears not to be so; on the contrary, none of the lives insured during any year commencing with the first of January, are entered in these statements as having come into the Society until the first day of January next following the day of their actual admission, and then each is stated to be one year older than it was when insured; although whatever deaths may happen amongst them before the first of January next following the commencement of the insurances, are entered in the statements as having taken place amongst the lives previously insured. The manuscript being wanted immediately, was in the hands of the printer, 400 miles from the author, before these circumstances were called to his recollection, by his accidentally seeing his original note on the subject; he is therefore anxious to give this explanation. The principle of the method of determining the law of mortality in such cases, remains just the same. But it now appears that the number stated in Table A to have been admitted at any age, should have been stated to be so at the next younger age, and any calculator who may choose to employ himself on the subject, had better make that correction before proceeding farther. The probable error arising from the fault will not be great; but it is incumbent upon us to state the right method of proceeding.

Mortality,
Law of.

59. The reason assigned by Lambert for voluntarily admitting this error at each age, as well as the corresponding one in the number of the living at and above the same age, into his table, was, that he did not consider the data in his possession enabled him to determine the duration of life within half a year of the truth.

60. In both these errors M. Lambert has been followed by J. C. Baumann, in constructing the 21st, 22d, and 23d tables inserted at the end of the third volume of Süssmilch's *Göttliche Ordnung* which were intended to represent respectively, the law of mortality among the country people in the churmark of Brandenburg, amongst the whole population of the churmark, and amongst the inhabitants of London.

61. The numbers in column Q were calculated by Deparcieux from Dr. Halley's table; and those in column R have been extracted from the 18th table in Dr. Price's *Observations*.

62. Upon comparing the numbers in the first six of these columns, which are more correct, with those in the last six, which are less so; it will be found, that at the early periods of life, its future mean duration according to the tables formed from mortuary registers alone, is less than according to those formed from the requisite data; also that the difference is greater the younger the lives are, and diminishes while the age increases, so as at 60 or 65 years of age to be little or nothing, and to continue small, and variable both in kind and magnitude, through the rest of life.

63. This appears to have arisen from the number of the people having varied but little during the first 35 or 40 years of the century that ended at or about the middle of the term in which the observations were made; and having increased considerably by procreation, during the remainder of that century; such increase having been slow at first, but gradually accelerated afterwards.

64. Table V. is calculated to illustrate this part of the subject. The columns A and B represent the law of mortality among the whole population of Sweden and Finland without distinction of sex, having been merely copied from Table II.

Column C shews the proportion of 10,000 annual deaths in Sweden and Finland that took place in each year of age, on an average of five years ending with 1805. And the number in column D against any age, being the sum of of those in column C against that and all the greater ages, would be the number who annually attain to that age, if the number of the people of every age had remained stationary from the year 1700 till 1806 (7).

65. The table of mortality formed by the columns C and D therefore, is that which Dupré de Saint Maur, Süssmilch, Lambert, Baumann, Florencourt, Muret and others, for want of the mortuary registers of a whole country, endeavoured to form by combining the registers of different town and country parishes.

Those tables also have the same faults, which have been formed in a similar way for particular towns or other comparatively small districts, from the bills of mortality alone, where the population had been increasing during the century preceding the commencement of the observations or statements in the bills of mortality which each table was formed from, and also during the period of the observations.

66. But it has been ascertained by repeated enumerations of the people in Sweden and Finland, that the hypothesis of their number having remained stationary for the last 100 years or more, is far from the truth. And by comparing columns A and B with C and D, it will be seen in what manner, and to what degree, the falsity of the hypothesis in this case, has vitiated the table derived from it.

67. To facilitate this comparison, columns E and F have been added. Taking the age of five years for an example; the numbers against that age in columns C and D show,

Mortality,
Law of.

that, according to the hypothesis, out of 5988 children who annually enter upon their 6th year, 144 die in it; while it appears by columns A and B, that out of 7096 children who enter upon that year of their age, only 112 die in it: and $112 : 7096 :: 144 : 9123$, so that 9123, inserted against the age of five years in column E, is the number of children annually entering upon their 6th year, out of whom 144 *really* die in the same year of their age; and the mortality as represented by the hypothetical table in this case, is to the true mortality, as 9123 to 5988, or as 3 to 2 nearly.

Then the number in column F against any age, is always the excess of that in E above that in column D against the same age.

68. Columns B and C both containing 10,000 deaths, it will be seen that in column C, they are greatly accumulated at the early ages, in comparison with those in column B; and that in old age, the deaths in column C are much less numerous than in B; which are necessary consequences of the people increasing by procreation; the numbers of the people in a progressive population, in comparison with a stationary one, being greater in early life, and less in old age. And, while the law of mortality remains the same, the numbers of deaths at the different ages, must necessarily be distributed in a similar manner.

69. This enables us to see clearly how the principal differences have arisen between the correct and incorrect tables of mortality AB and CD; whilst the number of annual deaths at all ages (10,000) is the same in both, the proportions of that number are necessarily in column C of the increasing population greater, and the deaths are more densely distributed at the early ages, and less so at the advanced ones than in column B of the population which has consisted of the same number of persons of every age, and has produced the same number of annual births and of annual deaths at every age for 100 years past. The increasing population is necessarily attended with a corresponding increase of the annual births and of young persons; while the elderly persons are only those left by the law of mortality out of the corresponding small numbers that were born annually, 50, 60, 70, or 100 years back. And as columns A and B represent the true law of mortality that prevails among the people, columns C and D cannot do so, although constructed from observations on the same people; for in an increasing population it is not true that the sum of the deaths happening annually above a given age will be the same as the number of persons annually arriving at or completing that age; it always falls short of it, and the more so as the given age is younger, there being deficiencies at all ages above that.

Columns E and F show what the errors of the hypothetical table are at the different ages, and they are of a similar kind in all tables similarly constructed from records of the number of deaths at the different periods of life in an increasing population; and such are probably 99 out of 100 of those hitherto published; many of them for people increasing their numbers much faster than the Swedes have done, and the errors of such tables must be greater than those of the table CD.

70. Table VI., which needs no further explanation than is placed at the head of it, will also illustrate the difference between tables of mortality formed from the requisite data, and those constructed from mortuary registers only.

It is better fitted for this purpose than Table IV., with which, however, it will be found to correspond very well. But the 4th table has other uses which this has not.

71. From what has already been advanced, it would appear probable, that the number of annual births in Sweden and Finland had been nearly stationary, and rather decreasing than increasing, upon an average, from about 1700 till 1735.

The numbers both of the annual births and deaths, from the year 1749 till 1803, will be found in Milne's *Treatise*

Mortality, on Annuities, art. 698: these kind of returns to government were not made before 1749, neither have we any satisfactory account of the population before that period.

72. But the statements in our 7th table corroborate the inferences just drawn from the 5th and 6th, as they shew that during the 43 years ended with 1800, the total population increased, while the proportion above 90 years of age diminished through the whole term, and increased very little during the next 10 years.

The numbers in that table include both sexes, and the long continued diminution of them past 90, cannot be explained by supposing the males to have fallen in battle; for the females were reduced in the same proportion, their number throughout, having been to that of the males above 90 years of age, as nine to five nearly.

From the 7th table, therefore, it appears probable, that the annual births in the years

1698, 1705, 1710, and 1715, were respectively proportional to the numbers..... 907, 637, 837, and 786.

The last number, 786, has been calculated upon the supposition that the proportion of the population in Sweden and Finland to those in Sweden alone, was the same in 1810 as in 1805.

73. It should also be observed here, that the disastrous career of Charles the Twelfth commenced with the eighteenth century, and terminated in 1718, when the country was in such a state of exhaustion as it could not have recovered from for many years; whence there appears reason to believe, that the annual births during the succeeding fifteen or twenty years, did not increase fast.

Cantzlaer informs us, that between the 10th of August 1710, and the month of February 1711, near 30,000 persons were carried off by the plague in Stockholm alone. (*Mém. du Royaume de Suède*, t. i. p. 29.)

74. It will be seen that the numbers in col. F of Table V., in proceeding back from four years of age to birth, continually decrease, contrary to what generally obtains; and as we ascribe the general increase of these numbers, when taken in the retrograde order of the ages, to the annually increasing number of births, so will this anomalous appearance be found to arise partly from the average number of annual births having actually *decreased* for a few years; for

During the five years ending with	The annual average number of births was
1800	107,690
1801	106,392
1802	105,504
1803	104,644
1804	105,430
1805	107,882

But it appears to have arisen principally from the practice of vaccination during the years 1804 and 1805, by which the mortality among children, or the numbers in col. C, in a few of the first years from birth, were reduced below what they otherwise would have been (50) while those in col. D remained nearly the same (64); consequently, the numbers in col. E were reduced in nearly the same ratio as those in C (67), and the reduction in col. F. was in each case nearly the same as in E (61).

75. The numbers relating to Sweden and Finland in the 7th table, have been derived from the Stockholm *Transactions* for the years 1766, 1801, 1809, and 1813.

Those relating to Spain and the Spanish possessions in Europe and Africa, including the Canary Islands, from the *Censo de la Poblacion de España en el año de 1797*, mentioned in the first section of this article. These last have been included in this Table, to show the difference in the proportion of aged persons between Spain and Sweden, and still more between the Canary Islands and both.

VOL. XV.

76. If the population of Spain had remained invariable from 1697 to 1797, the law of mortality there, might have been easily derived from the statements above mentioned of the enumeration in 1797; but in the actual state of things, that cannot be determined without comparing these with exact accounts of the numbers that died annually in each interval of age. And, as was observed in the first section of this article, the author has obtained satisfactory information that no such returns from the parish registers throughout Spain, as are there mentioned, ever were published, nor is it probable they were ever made.

77. When what we have advanced respecting the 5th and 6th tables is clearly understood, it will not be difficult to account for the greater part of the difference between the more and less correct columns in Table IV.

Most of the observations which the German tables were constructed from, were made between the years 1720 and 1750; and those who died then between 60 and 100 years of age, must have been born between 1620 and 1690; in which period nearly the whole of the thirty years' war, ended in 1648, was included, during which, and for several years after, it is probable that the annual births increased little or nothing, if they did not decrease.

78. Amongst the less correct columns of Table IV., those for Montpellier, Chester, and Geneva, agree much better than the rest with the more correct ones, which has probably arisen in each case, partly from the mortality in these three places having really been less throughout life than in most large towns; and partly from the annual births in them, having increased less than in the other places, during the fifty or sixty years preceding the period in which the observations the tables were constructed from were made.

79. The Northampton table was constructed by Dr. Price, from the bills of mortality (from the year 1735 to 1780) of the single parish of All Saints, containing a little more than half the inhabitants of the town; and as the deaths exceeded the births in number, the Doctor applied a correction to the table under twenty years of age, which, if it had answered the intended purpose under that age, as we are satisfied it did not, could have no effect on any of the numbers above the same age; and almost all of the useful applications of such tables, are to ages above twenty.

80. The table so formed could only be correct, provided that the numbers, both of the living and the annual deaths at every age above twenty years, had continued invariable during the 146 years that intervened between 1634 and 1780; provided also, that no migration from or to the town took place, except at twenty years of age, and that the annual increase the population received by migration at that age, was just equal to the excess of the annual deaths above the annual births.

81. But we consider it to be much more probable, that during these 146 years, Northampton partook of the prosperity and adversity that prevailed in the rest of the kingdom; and, consequently, that its population was generally progressive, though sometimes stationary, and sometimes retrograde.

82. We have not room here to support this opinion by numerical statements and calculations, but from the population abstracts, and an enumeration of the inhabitants of Northampton, given in Dr. Price's *Observations on Reversionary Payments*, (vol. ii. p. 94,) it will be found, that both the annual births, and annual settlers in that town, have been increasing ever since about the year 1715 or 1720; also, that although the burials exceeded the baptisms till the year 1802, the supply by migration was much greater than that excess; and, consequently, that the numbers of the living have been accumulated more at the early ages, and less at the advanced ones, than they would have been had the population remained stationary.

Mortality,
Law of.

83. Thus it appears, that the faults in the Northampton table are of the same kind as those of the others constructed from mortuary registers only. And the civil war in the time of Charles the First, with the unsettled state of the kingdom for some years before and after it, would probably have prevented or greatly retarded, the increase of the annual births, during the time in which those persons were born, who died past sixty years of age between the years 1734 and 1781, and may account for the table after that age being near the truth; while the comparatively rapid increase of the people during the sixty years ending with 1780, appears to explain the great excess of mortality in that table at the early periods of life.

84. As it was only from the Carlisle and Northampton tables of mortality, that tables of the values of annuities on single and joint lives had been calculated, sufficiently copious to admit of the values of interests dependent upon the continuance or the failure of human life being accurately derived from them. When the first edition of this article was published in the year 1820, the author gave the following comparison between the mortality represented by each of these tables to take place at the different periods of life, with that which had been observed to obtain among the members of the Equitable Assurance Society.

85. From an address delivered at a general court of that Society, by Mr. Morgan the actuary, on the 24th of April 1800, it appears, that according to the result of an annual experience of thirty years, the decrements of life (22) among the members of the society, were to those in the Northampton table,

Between the ages of 10 and 20	as 1 to 2.
20 — 30	— 1 — 2.
30 — 40	— 3 — 5.
40 — 50	— 3 — 5.
50 — 60	— 5 — 7.
60 — 80	— 4 — 5.

The same information may also be found in two notes in Dr. Price's *Observations on Reversionary Payments*, (vol. i. p. 183, and vol. ii. p. 449.)

86. From the preceding statement, the Carlisle table of mortality, (No. II. in Mr. Milne's *Annuities*, or No. V. at the end of the article *ANNUITIES* in this work, and the Northampton table, (No. XVII. in Dr. Price's *Observations*), we have derived the following:—

Out of	Who attain the age of	There die before the age of	According to the		
			Carlisle Table.	Experience of the Equitable Society.	Northampton Table.
Persons.	Years.				
6460	10	20	370	309	618
6090	20	30	448	443	886
5642	30	40	567	579	965
5075	40	50	678	652	1086
4397	50	60	754	900	1260
3643	60	80	2690	2244	2805

87. This table shows that the law of mortality exhibited in the Carlisle table is almost exactly the same as that which has prevailed among the members of the Equitable Assurance Society. And although the members of such a society, when they first enter, are select lives, they are not, even then, so much better than the common average, as many persons suppose; for the more precarious a life is, the stronger is the inducement for parties interested in its continuance, to get it insured, so that bad risks are frequently offered to such companies. And many proposals for insurance are accepted by the directors, that are not thought very eligible at the time, in cases where they are not aware of any specific objection to the life proposed.

88. Besides, it is to be considered, that of the number in a society at any one time, but a small proportion can have been recently admitted, and in a few years from the time of admission, the members will generally have come down to the common average of persons of the same ages.

89. It ought also to be observed, that most of the tables of mortality that have been published, have been constructed from observations made upon the whole population of very large towns, such as London, Paris, Vienna, and Stockholm; in each of which there are particular quarters inhabited only by the very lowest of the people, who, unfortunately, are also very numerous, badly clothed and fed, therefore exposed to serious injury from the inclemencies of the weather; extremely ignorant and vicious, indulging in the abuse of spirituous liquors, and inattentive to cleanliness both in their persons and habitations, which last are crowded, badly ventilated, and surrounded with mud and the putrid remains of animals and vegetables. These are the nests of contagious diseases, in which they are generated and kept alive, where they at all times occasion great mortality, though not so much within the last forty-five or fifty-five years as previously, and from which, when circumstances favour them, they spread amongst the rest of the people.

90. It is, therefore, obvious, that in such places, the average mortality at every age, must be considerably greater than that which prevails only among the middling and higher classes of society, even in such towns.

91. But the lives upon which leases, annuities, reversions, and assurances depend, are very seldom exposed to the influence of the causes of mortality mentioned in number 89. Whence it follows, that a table of mortality on which those causes have had no great influence, is best adapted to the valuation of such interests.

And these kind of valuations are the most important purposes to which tables of mortality can be applied.

92. The number of years in the *mean duration of life from birth* according to a table of mortality properly constructed from the necessary data, will, when the population has remained stationary for a century, or more, be the same as the number of persons in the whole population, out of which one dies annually (20). When the population has been increasing, the mean duration of life, according to the table, will be less than the number out of which one dies annually in that population; but the difference will be small, except under particular circumstances, as appears by the following statement.

93. The above mentioned table of mortality for Glasgow, which the author has had by him several years, he expects to publish soon.

The high number in the column of differences for females in that place, arises from the small mortality amongst them, which was occasioned principally by the great influx of healthy females between the ages of 15 and 30, at which period of life the rate of mortality amongst them was small; its *minimum* for them being in their 18th year.

Between the ages of 10 and 15 the numbers of the two sexes were just about equal, whilst between the ages of 15 and 30 the females were more numerous than the males in the ratio of 3 to 2; and this accounts for the great number of females (42·32), out of which one died annually there, which necessarily raises the number out of which one died annually in the whole population of both sexes, and there-

fore the number in the column of differences (in the line numbered 10) for the whole population of both sexes in Glasgow.

94. Similar causes probably produced similar effects, although in a much less degree in Stockholm.

95. When tables of mortality are constructed from the numbers of deaths only in the different intervals of age, without comparing them with the numbers of living persons in the same intervals; such as that formed by columns C and D of Table V. at the end of this article, and the population is increasing. The number of years in the mean duration of life from birth, according to that table, will fall short of the number of the people, out of which one dies annually, by a much greater number than in the case we have just been considering, of the table of mortality having been properly constructed from the necessary data: as the following statement will show.

	Place.	Years.	Term of the Observations.	Died annually, one of	Mean Life.	Difference.	Authorities.

96. In both of the above statements, where the sexes are not mentioned, the table is for both without distinction.

97. In places where the increase of the population was slow, the numbers set against them in the column of differences are smaller than where the population increased more rapidly.

98. In the tables of mortality for Belgium and Montpellier, the sexes were distinguished, but not in the given number of the whole population, as well as the whole number of deaths in each of those places, and for that reason the sexes could not be distinguished for those two places in this last table.

99. When what we have shewn here is clearly understood,

and the proportion of the people dying annually is known, it will not be difficult to judge whether a table of mortality for that people has been constructed properly from the necessary data; or, what is much more common, and more easily effected, merely by summation of the deaths at all ages. For in the case of the correct table of mortality, the difference obtained in the manner stated above, will probably not exceed 2; nor in the case of the incorrect table, will it be likely to be less than 7, upon the supposition of the population having increased generally for a considerable number of years preceding the termination of the observations; if for a whole century, so much the better.

¹ But omitting the year 1764, in which no observations were made.

Mortality,
Law of.

100. The probable life at birth, or the age to which half the number born attain, will also be a good criterion for enabling us to judge, by comparison, whether a table of mortality has been correctly constructed from the necessary data or not; provided that, in the places the compared tables have been constructed from, the children have been similarly circumstanced, or nearly so.

According to the	The probable duration of life from birth, is	
	10 years of age, is	
Correct table for Sweden, in this article,	45 years.	53 years.
Incorrect one,	22 —	48 —
Belgian table,	25 —	48 —

In Belgium vaccination was practised during the whole period of the observations, in Sweden only during about $1\frac{1}{2}$ out of the 5 years' observations.

101. From all that has now been stated, we are entitled to conclude, that the Belgian table of mortality has been constructed either from the registers of burials alone, or only from the statements of the numbers living in the different intervals of age at the time of the enumeration; most probably from the burials alone. M. Quetelet appears now to be aware that such tables are very incorrect. In his late work *sur l'Homme et le Développement de ses Facultés, ou Essai de Physique Sociale*, 2 tom. Paris 1835, in 8vo, after giving the above mentioned table of mortality for Belgium, in which only the numbers attaining the different ages are given, without the decrements of life, or its mean or probable duration at the different ages, he states the mean duration of life from birth according to that table, and then proceeds thus, (tome i. p. 166):—"D'après le dernier ouvrage de M. Rickman, la vie moyenne serait en Angleterre de 33 ans (32 pour les hommes, 34 pour les femmes).¹ On l'estime en France de 32·2 ans d'après le chiffre des naissances.² Du reste, ces calculs supposent une population stationnaire, et nous aurons occasion de voir qu'ils peuvent conduire à des erreurs assez graves."

102. Reasoning as in Nos. 68 and 69, it will be seen that when the number of the people has been decreasing for a series of years, the deaths will be more densely distributed among the advanced ages, and more rarely in the early periods of life, than if the number of the people at every age, and the law of mortality had remained always the same. Consequently, in the table of mortality constructed from such data, merely by taking the successive sums, in retrograde order, from extreme old age to birth; those successive sums, which are the numbers of the living at the different ages in the table so constructed, will be greater at advanced ages and less in early life than if the population had remained stationary, as stated above. So that the errors of the incorrect table would, in this case, be of the opposite kind to those of the common tables, constructed in a similar way from the deaths only, in an increasing population. From the general increase of arts, manufactures, commerce, and civilization, ever since tables of mortality were first formed, the population has been increasing more or less rapidly in almost every place, for which a table of mortality has been constructed. But in Amsterdam we have an instance of the population having continued to decrease for half a century or more. We here present a view of it since the year 1622.

Population of Amsterdam.

103. The information on this subject is scanty and difficult to procure. Kersseboom took much pains in endeavouring to make just estimates of the population from the annual births and deaths; and taking it to be 35 times the number of annual births, he estimated the population of Amsterdam in 1742 at 241,000 persons.

Three only of the six numbers stated above, viz. those for the years 1622, 1826, and 1830, were determined by actual enumerations at the times stated. Although M. Smits, the secretary of the Statistical Commission, relative to the population of the Netherlands, is not mentioned in the above table, we are greatly indebted to him. In his *Statistique Nationale* he gave a table, (No. 10, p. 82), shewing the number of deaths that took place in Amsterdam in each year of the 18th century. M. Lobatto has given them in the place above referred to for each of the ten years 1816–1825; and M. Quetelet, in the part of his work referred to above, has given them for each of the 17 years, 1816–1832, and states that in the year 1777 the mortality was 1 in 27; the number of deaths in that year was 8939, whence the population inserted in the table is derived. M. Lobatto states, on the authority of Professor Van Swinden and of M. Nieuwenhuys, that from 1774 to 1813 there died annually 1 of 26; the deaths in 27 years, 1774–1800, were 233,510, the annual average number, therefore, was 8648·5, and multiplying this by 26, we obtain 224,862, the mean number of the people during these 27 years, which is stated in the above table to have been the population in 1787, the middle year of the 27.

104. The enumeration in 1622 was made in levying a capitation tax, which was exacted with great strictness, even in every receptacle for paupers, the master or owner of it was obliged to pay the tax for each inmate. This enumeration appears not to have been known of, either by Kersseboom or by Struyck at the time of his first publication on the subject; but an original paper, with many particulars which he gives, was afterwards communicated to him. Struyck, after taking great pains with the subject, stated his opinion, that in 1753, Amsterdam did not contain 200,000 inhabitants.

105. M. Lobatto, at the end of his *Beschouwing*, &c. gives two tables of mortality for Amsterdam, one for males, the other for females, constructed from the deaths that took place during the ten years 1816–1825, with the expectation of life at every age, and we here give the same particulars for it as are given for some others above, but marking the difference (—) as it is of the opposite kind to those which resulted from an increasing population.

³ *Beschouwing van den aard, de voordelen, en de inrigting der Maatschappijen van Levensverzekering*, &c., door R. Lobatto; Amsterdam, in 8vo, 1830.

Mortality, Law of. 106. This low mortality of one in 29·22 was obtained by M. Lobatto stopping at the year 1825, which he himself states was on account of the mortality having been high in the two following years, 1826 and 1827. He obtained the annual mortality of 1 in 29, by dividing the number of the people in 1826, the year after the end of the term, by the annual average number of deaths during the term. During the 12 years 1821–32, of which 1826 was the middle one, the annual average number of deaths was 7,336·18, and there died annually, on an average, one of 27·369; the difference in the above statement should therefore be —4·85, Mortality, Law of. or nearly 5; which is the true excess of the number of years in the mean duration of life, above the number of persons out of which one died annually.

107. For some of the most important applications of the facts and inferences stated in this article, the reader is referred to the article ANNUITIES in this work, where he will find that the valuation of ASSURANCES or REVERSIONS dependent upon lives is also treated of.

The Table may be read thus:—Of 100 Males living of the age of 35 and under 45, 1-342 died in 1838, 1-255 in 1839, 1-217 in 1841, and so on for other years; a correction for increase of Pop. having been made for each Age at each Year. (The data upon which these Tables are constructed appeared in the Census Report for 1851; and in the Ann. Reps. of the Reg. Gen., particularly the 6th.)

Mortar
Mortimer.

MORTAR, a chemical utensil, used for the division of bodies, partly by percussion and partly by grinding. Mortars have usually the form of an inverted bell, and are made either of iron, stone, stoneware, or glass, &c., according to the use to which they are applied. For the finer chemical processes they are often composed of agate, flint, or porphyry. The matter intended to be pounded is put into them, and then struck and bruised by an instrument denominated a *pestle*.

MORTAR, in the military art, is a short cannon of a large bore, with chambers. It is made of brass or iron, and is used to project hollow shells, filled with powder, called bombs, and sometimes also carcasses. (See **ARTILLERY**.) The mortars used at sea are fixed in bomb-vessels, which are constructed for their reception; they are made somewhat longer and much heavier than those employed on land. The mortar is the most ancient kind of cannon, and was first made in England in 1543. (See **GUNNERY**.)

MORTARA, a walled town of the kingdom of Sardinia, in Italy, the capital of the province of Lomellina, is situated on an eminence on the right bank of the Arbogna, which is here crossed by a bridge, 14 miles S.S.E. of Novara. The principal buildings are,—three churches, a court-house, a theatre, several schools, and an hospital. There is some trade in rice, grain, and silk. The situation of the town is unhealthy; and from this circumstance it is said to derive its name, being a corruption of *mortis ara*. Another account, however, derives this name from the battle fought here in 774 A.D., when the Lombards were defeated by Charlemagne with great slaughter. Pop. 5316.

MORTIER, **EDOUARD-ADOLPHE-CASIMIR-JOSEPH**, Duke of Treviso and Marshal of France, was born at Chateau-Cambresis in 1768. At the age of twenty-three he entered the army of the Revolution as captain in a battalion of volunteers. He fought with distinction at the battles of Jemeppe and Neerwinden, and was gradually promoted. In 1799 the rank of general of brigade had been conferred upon him. Serving soon afterwards as a general of division in the army of Switzerland, he led the right wing of Massena's forces in the battle of Zurich. His next important service was the occupation of the electorate of Hanover in 1803. On his return in the following year, his valour was publicly acknowledged by Bonaparte; and a marshal's baton and the rank of general of the consular guard were conferred upon him. He supported his reputation at the battle of Friedland in 1807. The title of Duke of Treviso was bestowed upon him in 1808. At the head of the 5th corps in the army of Spain he defeated the Spaniards at Ocana in 1809, and at Jebora in 1811. He served under Napoleon in the Russian expedition, and at all the important battles of 1813 and 1814. In this latter year the defence of Paris against the victorious allies was entrusted to him and Marshal Marmont. He was one of those who sent in their allegiance to Louis XVIII. at the commencement of the Hundred Days, recalled it when Napoleon landed from Elba, and renewed it after the battle of Waterloo. Yet his attachment to the Bourbons did not prevent him, after the Revolution of 1830, from rising into favour with Louis Philippe. He was riding by the side of that monarch at a review of the National Guard of Paris, on the 28th July 1835, when the infernal machine of Fieschi, intended for the destruction of royalty, exploded. Marshal Mortier was among the number of those who were struck dead on the spot.

MORTIMER, **JOHN HAMILTON**, a noted artist, was the son of a collector of customs, and was born at Eastbourne in Sussex in 1741. His early-developed talent for painting found congenial subjects among the rocks and woods of his native shore. He repaired to London about his eighteenth year, and studied his art first under Hudson, and afterwards under Pine. At the same time he executed

Mortmain.

several imitations of the antique figures in the gallery of the Duke of Richmond. Some of these secured for him premiums from the Society for the Encouragement of Art, and facilitated his admission into the private academy in St Martin's Lane. But his first introduction to general notice was his representation of "Edward the Confessor seizing the Treasures of his Mother," a painting which, by the judgment of Sir Joshua Reynolds, received the prize of fifty guineas, in preference to a rival picture by Romney. His great work, "St Paul preaching to the Britons," was executed soon afterwards, and raised him to the height of popularity. Yet owing to his rapidity of execution, and his tameness in colouring, Mortimer did not reach a high excellence in historical painting. He excelled far more in the designs which he threw off for the booksellers. In these his facile hand sketched with unerring skill the forms that his happy fancy conceived or his well-stored memory suggested. He was also unrivalled in his feats of rapid and dexterous drawing; and in his creation of fantastic and striking images. This eccentricity and fondness for display was not confined merely to his art,—it extended also to his ordinary life. Gaudy dress, convivial pleasures, athletic contests, and grotesque buffoonery, occupied a great part of his time and attention. At length he married and settled down into sobriety of life, but not before his constitution had become prematurely weak. In 1775 his health began to decline, and rendered it necessary that he should retire into the pure air of the country. His rapid power of painting, however, remained unimpaired; and in his rural retreat at Aylesbury in Berks he produced in one year a number of pictures of the united value of L.900. He returned to London in 1778, and died of a fever in February of the following year. The best known historical paintings of Mortimer, in addition to the two already mentioned, are "King John signing the Magna Charta," "The Battle of Agincourt," "The Origin of Health," "The Tragic and Comic Muses," "Sextus consulting Erietho from Lucan," "The Incantation," and "Vortigern and Rowena." (See Cunningham's *Lives of British Painters*, &c.)

MORTMAIN, or **ALIENATION IN MORTMAIN** (*in mortua manu*), is an alienation of lands or tenements to any corporation, sole or aggregate, ecclesiastical or temporal. But these purchases having been chiefly made by religious houses, in consequence of which the lands became perpetually inherent in one dead hand, this occasioned the general appellation of *mortmain* to be applied to such alienations, and the religious houses themselves were principally considered in framing the statutes of mortmain. In deducing the history of these statutes, it will be matter of curiosity to observe the great address and subtle contrivance of the ecclesiastics, in eluding from time to time the laws in being, and the zeal with which successive Parliaments pursued them through all their finesses; how new remedies were still the parents of fresh evasions, until the legislature at last, though with difficulty, obtained a decisive victory.

By the common law, any man might dispose of his lands to any other private man at his own discretion, especially when the feudal restraints of alienation were worn away. Yet in consequence of these it was always, and still is, necessary for corporations to have a license of mortmain from the crown, to enable them to purchase lands; for as the sovereign is the ultimate lord of every fee, he ought not, unless by his own consent, to lose his privilege of escheats and other feudal profits, by the vesting of lands in tenants who can never be attainted or die. Such licenses of mortmain appear to have been necessary amongst the Saxons above sixty years before the Norman conquest. But, besides this general license from the King as lord paramount of the kingdom, it was also requisite, whenever there was a mesne or intermediate lord between the King and the alienator, to obtain his license also for the alienation of the

Mortmain. specific land; and if no such license was obtained, the King or other lord might respectively enter on the land so alienated in mortmain, as a forfeiture. The necessity of this license from the crown was acknowledged by the Constitutions of Clarendon, in respect of advowsons, which the monks always greatly coveted, as forming the groundwork of subsequent appropriations. Yet such were the influence and ingenuity of the clergy, that notwithstanding this fundamental principle, we find that the largest and most considerable donations of religious houses happened within less than two centuries after the Conquest. When a license could not be obtained, they contrived that, as the forfeiture for such alienations accrued in the first place to the immediate lord of the fee, the tenant who meant to alienate should first convey his lands to the religious house, and instantly take them back again to hold as tenant to the monastery, which kind of instantaneous seisin was probably given not to occasion any forfeiture; and then, by pretext of some other forfeiture, surrender, or escheat, the society entered into those lands in right of such their newly-acquired signiory, as immediate lords of the fee. But when these donations began to grow numerous, it was observed that the feudal services ordained for the defence of the kingdom were every day visibly withdrawn; that the circulation of landed property from man to man began to stagnate; and that the lords were curtailed of the fruits of their signiories, their escheats, wardships, reliefs, and the like. To prevent this, therefore, it was ordained by the second of King Henry III.'s great charters, and afterwards by that printed in the common statute-books, that all such attempts should be void, and the land forfeited to the lord of the fee.

But as this prohibition extended only to religious houses, bishops and other sole corporations were not included therein; and the aggregate ecclesiastical bodies, who had among their counsel the most learned men that they could get, found many means to creep out of this statute; by buying in lands which were *bonâ fide* holden of themselves as lords of the fee, and thereby evading the forfeiture; or by taking long leases for years, which first introduced those extensive terms, for a thousand or more years, which are now so frequent in conveyances. This produced the statute *De Religiosis*, 7 Edward I., which provided, that no person, religious or other whatsoever, should buy or sell, or receive under pretence of a gift, or term of years, or any other title whatsoever, nor should by any art or ingenuity appropriate to himself any lands or tenements in mortmain, upon pain of the immediate lord of the fee, or in default of him for one year the lords paramount, and in default of all of them the King, entering thereon as a forfeiture.

This seemed to be a sufficient security against all alienations in mortmain. But as these statutes extended only to gifts and conveyances between the parties, the religious houses now began to set up a fictitious title to the land which it was intended they should have, and to bring an action to recover it against the tenant, who, by arrangement and collusion, made no defence; and thereby judgment was given for the religious house, which then recovered the land by a sentence of law upon a supposed prior title. And thus they had the honour of inventing those fictitious adjudications of right which afterwards became the great assurance of the kingdom, under the name of *common recoveries*. But upon this it was enacted by the second statute of Westminster, 13 Edward I., c. 32, that in such cases a jury shall try the true right of the demandants or plaintiffs to the land; and if the religious house or corporation be found to have it, they shall still recover seisin; otherwise it shall be forfeited to the immediate lord of the fee, or else to the next lord, and finally to the King, upon default of the immediate or other lord. A similar provision was made by the succeeding chapter, in case the tenants should set up crosses upon their lands, the badges of knights templars and

hospitallers, in order to protect them from the feudal demands of their lords, by virtue of the privileges of those religious and military orders. And so careful was this prince to prevent any future evasions, that when the statute of *Quia emptores*, 18 Edward I., abolished sub-infeudations, and gave liberty to all men to alienate their lands to be holden of their next immediate lord, a proviso was inserted that this should not extend to authorize any kind of alienation in mortmain. When, afterwards, the method of obtaining the King's license by writ of *ad quod damnum* was marked out by the statute 27 Edward I., st. 2, it was further provided, by statute 34 Edward I., st. 3, that no such license should be effectual without the consent of the mesne or intermediate lords.

Yet still it was found difficult to set bounds to ecclesiastical ingenuity; for when the clergy were driven out of all their former holds, they devised a new method of conveyance, by which the lands were granted, not to themselves directly, but only to nominal feoffees for the use of the religious houses, thus distinguishing between the possession and the use, and receiving the actual profits, whilst the seisin of the land remained in the nominal feoffee, who was held by the courts of equity, then under the direction of the clergy, to be bound in conscience to account to his *cestuy que use* for the rents and emoluments of the estate. And it is to these inventions that our practitioners are indebted for the introduction of uses and trusts, the foundation of modern conveyancing. But unfortunately for the inventors themselves, they did not long enjoy the advantage of their new device; for the statute 15 Richard II., c. 5, enacts, that the lands which had been so purchased to uses should be admortised by license from the crown, or else be sold to private persons; and that for the future, uses should be subject to the statutes of mortmain, and forfeitable like the lands themselves. And as the statutes had been notoriously eluded by purchasing large tracts of land adjoining to churches, and consecrating them by the name of "churchyards," such subtle imagination was also declared to be within the compass of the statutes of mortmain. Civil or lay corporations, as well as ecclesiastical, were also declared to be within the mischief, and of course within the remedy provided by those salutary laws. Lastly, as during the times of Popery lands were frequently given for superstitious uses, though not to any corporate bodies, or were rendered liable in the hands of heirs and devisees to the charge of obits, chantries, and the like, which were equally pernicious with actual alienations in mortmain; therefore, at the dawn of the Reformation the statute 23 Henry VIII., c. 10, declared that all future grants of lands for any of the purposes aforesaid, if granted for any longer term than twenty years, should be void.

But during the whole of this time it was in the power of the crown, by granting a license of mortmain, to remit the forfeiture, as far as related to its own rights, and to enable any spiritual or other corporation to purchase and hold any lands or tenements in perpetuity—a prerogative which is declared and confirmed by the statute 18 Edward III., st. 3, c. 3. But as doubts were entertained at the time of the revolution how far such license was valid, since the King had no power to dispense with the statutes of mortmain by a clause of *non obstante*, which was the usual course, though it seems to have been unnecessary; and as by the gradual declension of mesne signiories through the long operation of the statute of *Quia emptores*, the rights of intermediate lords were reduced to a very small compass; it was therefore provided by the statute 7 and 8 William III., c. 37, that the crown for the future, at its own discretion, might grant licenses to alienate or take in mortmain, of whomsoever the tenements might be holden.

After the dissolution of monasteries under Henry VIII., though the policy of the next successor affected to grant

Morton. a security to the possessors of abbey lands, yet, in order to regain as much of them as either the zeal or timidity of their owners might induce them to part with, the statutes of mortmain were suspended for twenty years; and during that time any lands or tenements were allowed to be granted to any spiritual corporation without any license whatsoever. And long afterwards it was enacted by the statute 17 Car. II., c. 3, that appropriators might annex the great tithes to the vicarages, and that all benefices under L.100 per annum might be augmented by the purchase of lands without license of mortmain in either case; and the like provision has been since made in favour of the governors of Queen Anne's Bounty. It has also been held, that the statute 13 Henry VIII. before mentioned did not extend to anything but superstitious uses, and that therefore a man may give lands for the maintenance of a school, an hospital, or any other charitable uses. But as it was apprehended from recent experience that persons on their deathbeds might make large and improvident dispositions even for these good purposes, and defeat the political ends of the statutes of mortmain, it was therefore enacted by the statute 9 Geo. II., c. 36, that no lands or tenements, or money to be laid out thereon, should be given for or charged with any charitable uses whatsoever, unless by deed indented, executed in the presence of two witnesses twelve calendar months before the death of the donor, and enrolled in the Court of Chancery within six months after its execution (except stocks in the public funds, which may be transferred within six months previous to the donor's death), and unless such gift were made to take effect immediately, and were without power of revocation; and that all other gifts should be void. The two universities, their colleges, and scholars upon the foundation of the colleges of Eton, Winchester, and Westminster, were excepted from the operation of this act; but such exemption was granted with this proviso, that no college should be at liberty to purchase more advowsons than were equal in number to one moiety of the fellows or students upon the respective foundations.

Such is the history and condition of the law of mortmain, as stated by Blackstone (*Com.*, b. ii., c. 20). It has been to a certain extent modified by recent statutes. The Church-Buildings Acts, consolidated in 1840 (3 and 4 Vict., c. 60), exempted from the license in mortmain endowments for the sites of churches, parsonages, or glebes, "or for the use or benefit of any church or chapel, or of the incumbent or minister thereof, or for repairs thereof." There have been further partial changes in the Church-Buildings Acts, the latest in 1851 (14 and 15 Vict., c. 97), and property dedicated to purposes of education. A reference will be found to several of the statutes containing these modifications in the act 15 and 16 Vict., c. 49.

MORTON, CARDINAL JOHN, was born at Bere in Dorsetshire in 1410. He was educated at Baliol College, Oxford, and became principal of Peckwater Inn, now merged in Christ Church. His learning and talents introduced him to Cardinal Bouchier, and thus set him on the path to preferment. He was recommended to the notice of Henry VI., and was appointed a member of the Privy Council. Not less successful in the reign of Edward IV., he was nominated Bishop of Ely and Lord Chancellor of England in 1478, and was finally appointed one of the King's executors. His tried probity, however, did not fit him for the lawless service of the next King, Richard III., and he was imprisoned in the Castle of Brecknock. But contriving to escape, he fled to the Earl of Richmond on the Continent, and is said to have been the first who proposed a marriage between that prince and Elizabeth, the eldest daughter of Edward IV. At the death of Richard III., and the accession of Henry VII., a succession of preferments awaited Morton. He was appointed a privy-councillor; he was raised to the see of Canterbury in

1486; the chancellorship was again conferred upon him in 1487; and Pope Alexander VI. created him a cardinal in 1493. His death took place in September 1500.

MORTON, Thomas, a successful writer of comedy, was born at Durham in 1764. After attending school at London, he enrolled as a student of Lincoln's Inn; but his love for dramatic amusements led him to spend his evenings in the theatres, and to study the drama more than the law. The knowledge of stage effect which he thus acquired was employed in the production of numerous plays. By their skilfully-arranged scenes, their strongly-contrasted characters, and their sudden transitions of feeling, these dramas secured the attention of mixed audiences. The acting of Lewis, Munden, and Emery greatly increased their effect. Accordingly, several of them, such as *The Way to get Married*, *A Cure for the Heart-Ache*, *Speed the Plough*, *The School of Reform*, and *The Invincibles*, secured a footing on the stage, which they still retain. Morton died in 1838.

MOSAIC, or **MOSAIC WORK**, an assemblage of little pieces of glass, marble, precious stones, and other substances, of various colours, cut in prisms, and fixed in a ground of cement, in such a manner as to imitate the colours and gradations of painting. This sort of work was used both for pavements and for ornamenting walls until a comparatively late period in the middle ages. It was much practised by the Byzantine artists, who re-introduced it into Italy. The most famous kinds of mosaic of recent times are the Roman and the Florentine. Pictures in mosaic were wrought at Rome in the eleventh and twelfth centuries. Some of the finest specimens of mosaics in existence are to be found in St Peter's at Rome. The origin of the name *mosaic* has not been accurately determined. The most probable derivation, however, is from the Greek *μουσειον*, Lat. *opus musivum*. (See the *Glossarium* of Ducange.)

MOSCHUS, a Greek bucolic poet, flourished at Syracuse about the close of the third century B.C. His genius was fostered by a study of the works, and probably by the friendship, of the pastoral poet Bion. He was also, according to Suidas, acquainted with the grammarian Aristarchus. Theocritus was his great model; but instead of the exquisite simplicity of that celebrated poet, he often displayed an excess of ornament and an over-refinement of style. His four extant idyls are *Fugitive Love*, *Europa*, *An Elegy on Bion*, and *Megara*. They have been usually edited with the works of Bion. (See *BION*.) Many modern writers of different nations have imitated and translated them.

MOSCOW, the ancient capital of Russia, is situated in the government of the same name, in 55. 45. 13. N. Lat., and 55. 17. 11. E. Long., 698 versts, or 466 English miles, from St Petersburg, and 1349 versts, or 902 English miles, from the frontiers of Poland. The soil in its immediate neighbourhood is sandy and argillaceous. A great part of it is under cultivation, and is highly productive. The situation of Moscow is most happily chosen.

The town is divided into two unequal parts by the River Moskva. On the left bank, on which the larger part of the city stands, the surface is broken and hilly. On the right, at the distance of about a mile, rises an amphitheatre of low hills, covered with wood, called the Sparrow Hills, from the summit of which you obtain a fine view of the city. At your feet the river winds through beautiful meadows; rising beyond, you see a mingled mass of towers, gilded and painted domes, churches, monasteries, and palaces. The whole, when seen on a sunny day and under a clear sky, possesses an almost unearthly splendour, from the dazzling whiteness of the buildings, and the glancing brilliance of the gilded domes of the churches.

The River Moskva rises in the S.E. of the government of Moscow, towards the district of Mojaik. Its course is very winding, and hence its name, which signifies "the winding" or "serpentine." In spring it becomes navigable

Morton
||
Moscow.

Moscow. by the melting of the snow and ice, and then by means of the River Oka, its junction with which falls into the Volga, affords a communication between Moscow and that great river.

The length of Moscow from the Sparrow Hills on the S.W. to the Preobrajensky Barrier on the N.E., is about 14 versts, or 10 English miles. Its width from E. to W. is about 10 versts, or 7 English miles; its circumference is about 20 English miles. It covers a larger extent of ground than any other European capital, excepting London and Constantinople.

Moscow is divided into three distinct circles within the rampart or earthen walls thrown round the whole city. The first or most remote from the centre is called the *Zemlianoi Gorod*, or Earth City. It lies between a line of streets called the *Sadova*, or Garden Street, because most of the houses have a garden or inclosure in front, and the Boulevards. The second division, the *Beloi Gorod*, or White City, is that part of the town which lies between the Boulevards and the *Kitai Gorod*. The general form of the Boulevards is that of an avenue of lime-trees for foot-passengers, on either side of which runs a carriage-road or street, the intervening space being filled up with clumps of small trees, shrubs, and flowers. The *Beloi Gorod* is the most aristocratic division of the town. The last circle is inclosed by an embattled wall, and covers a very extensive space of ground. It is almost entirely occupied by what is termed the *Gosteeny-dvore*, an immense mass of buildings divided into rows of shops, warehouses, and store-houses, each row being devoted to the sale of a particular kind of goods, and having the name of the article sold,—as, *e.g.*, Knife Row, Linen Row, Silk Row, Plate Row, &c. This division is called the *Kitai Gorod*, or Chinese Town. The origin of the name is not exactly known. One hypothesis is, that it was called after a small town of Lithuania of the same name, which was the birthplace of Helen, mother of Ivan IV., who built this division of the town. The most probable account of the name is, that it was at one time the great mart for Chinese goods. When, however, it is spoken of separately from the other divisions, it is simply called “Gorod,” just as in London we speak of the “City.” It may be added, that in other respects it bears a striking analogy to the “City” of London, being the centre of trade and business, and having within its limits the great commercial and civic buildings.

On the S.W. of the *Kitai Gorod*, and separated from it by a large square called the *Crassnaia*, or Red Square, stands the Kremlin, the ancient fortress of the city. It is built on the brow of a hill, at the foot of which flows the Moskva River. Its form is irregular, but almost approaching a triangle. A high crenellated wall surrounds it, broken at intervals by towers of various heights, and of pyramidal or spiral form. On three sides runs a sort of boulevard; and on the fourth side, over the bed of a small stream called the *Neglinna*, which is now conveyed by an underground canal into the Moskva, is a large public walk called the Alexander Gardens, from having been laid out by order of the Emperor Alexander I. These gardens are the work of a Scotchman. Taken as a whole, the Kremlin is one of the most original, beautiful, and striking objects that can well be conceived. Its commanding situation on the banks of the Moskva River; its high and venerable white walls, with its variously-coloured towers and steeples; the number and size of some of its fine buildings, with their painted roofs; the cathedrals, churches, monasteries, and belfries, their domes gilt, tin-plated, or green;—the whole presents a grandeur and beauty indescribable and altogether unique.

The interior of the Kremlin contains the imperial palace, a modern erection, replacing the older one, which in former days had been occupied by the Tsars, and in which Napoleon had spent a part of his disastrous sojourn in Mos-

cow. Though a fine and spacious building, it strikes the eye as out of character with the general style of the Kremlin. Behind the new palace is a small one of great antiquity. The rooms have vaulted ceilings, completely covered with arabesque paintings, exceedingly rich and curious.

The cathedrals are three in number,—the Church of the Assumption, built in 1472 A.D., where the Emperors of Russia are always crowned; the Church of the Archangel Michael, where, until St Petersburg was built, the Tsars were buried; and the Church of the Annunciation. Near these churches stands the *Ivan Veliki* tower, or Tower of John the Great. It was built by Boris Goudanoff about the year 1600. The best view of Moscow is to be obtained from it, as it commands more objects than that from any other place.

At the foot of the Kremlin stands the great bell of Moscow, said to be the largest in the world. Its circumference at the bottom is nearly 68 feet, and its height more than 21 feet. In the stoutest part it is 23 inches thick, and its weight has been computed to be 443,772 lb. It has never been hung, and was probably cast on the spot in which it now stands. When Dr Clarke visited Moscow in the year 1800 it was in a pit, the mouth of which was covered, and the entrance was by a trap-door, beneath which were ladders. Since then it has been raised, and now stands on a stone pedestal. A piece of the bell has been broken off. The fracture was occasioned, according to Dr Clarke, by water having been thrown upon it when heated by the building erected over it being on fire.

The other buildings of importance in the Kremlin are,—the Granite Palace or treasury, where the crowns, sceptres, coronation robes, &c. &c., are kept; the Senate-House; the Tchoudoff monastery; the Arsenal, along the outside of which lie a great number of cannon, most of them foreign, and taken in the campaign of 1812-14. Amongst them are two Russian cannon of immense size; the mouth of the largest is about 2 feet 6 inches in diameter; the weight of the metal is 2200 poods; the ball weighs 80 poods, or about 1 ton.

The Kremlin is approached by five gateways. One facing N.W., and opening into the Great Square, which divides the Kremlin from the *Kitai Gorod*, is called the *Spaskoi Varott*, or Gate of the Saviour, and sometimes the Holy Gate. Through this gate no male person is allowed to go without taking off his hat. Outside this gate stands one of the most remarkable buildings in Moscow,—the church of Vassili Blashenny, or Basilus the Blissful, erected by Ivan the Terrible after the conquest of Kasan—the work of an Italian architect. It is a strange blending of every imaginable style of architecture, thrown together in the most capricious and fanciful manner. In its principal feature, however, it is Tartar, and bears a strong resemblance to the oriental mosque. Its numerous and heavy cupolas, surmounted by gilded crosses, exhibit a striking contrast of colour and ornament.

Another gate of the Kremlin, also facing the N.W., and opening into the Great Square, is called the *Nicholskoi Varott*, or Gate of St Nicholas, and was the one blown up by the French. It has been restored with considerable taste and elegance.

About the middle of the Great Square is a monument consisting of the statues of Minim, citizen of Novogorod, and Prince Pojarsky, who together delivered Moscow from the Poles; an event which was followed by the election of Michael Feodorovitch, the first of the Romanoff dynasty, to the throne.

Among the remarkable buildings of Moscow should be mentioned the Church of our Saviour, not yet quite finished, erected in commemoration of the retreat of the French after the burning of Moscow in 1812. It was begun on the edge of the Sparrow Hills, and near the

Moscow.

Moscow. spot where Napoleon took his first view of Moscow; but the ground giving way, the site was changed to the spot on which it now stands, on the opposite side of the river. The building is in the Byzantine style of architecture, and with its gilded domes is a conspicuous object, seen from every side of the city.

Another remarkable building, standing on high ground, in the Zemlianoi Gorod is the *Sukareva Bashnoi*, or Tower of Sukareff. It is now used as a reservoir to receive the water with which Moscow is supplied. The water, which is of excellent quality, is brought from the far-famed springs of Metischa, forty-two in number. From the Sukareva Bashnoi it is conveyed by underground pipes to fountains in various quarters of the town. The whole was done by order of Katherine II.

The Foundling Hospital, a magnificent pile of building on the banks of the Moskva, was founded by Katherine II. in 1763. Any person may bring an infant, and without giving any further information than whether it has been baptized, may leave it there. If at any future time the parents wish to have the child again, a card is given them with the number in which it is entered in the register of the establishment, the same number being hung round the child's neck. Connected with this hospital is a school for the education of orphan young ladies of noble birth; also a Lombard or loan bank, and a widow alms-house for the widows of civil officers.

Of the educational establishments of Moscow, the university is divided into 4 faculties, and had, in 1857, 40 professors and lecturers, and 1473 students. Of these last 63 belonged to the historico-philological faculty, 296 to the law, 950 to the medical, and 160 to the mathematical. The cadet corps, or military schools, are 3 in number, containing altogether 1285 cadets. The gymnasia, or public schools, are 4 in number. There is 1 commercial academy and 1 commercial school, 1 seminary for the education of the clergy, 1 academy for divinity students who desire a superior education to that given in the seminary. The Katherine Institution, founded by Katherine II., is devoted to the education of young ladies, and contains 290 pupils. The Elizabethan Institution, founded by the Empress Elizabeth, contains 173 pupils. The house of education in connection with the Foundling Hospital, already referred to, contains 700 pupils.

The number of churches is 375; of chapels, *i.e.*, places of worship connected with public institutions, 26; of monasteries, 21.

Moscow is a great centre of internal commerce, its position being peculiarly favourable for this. Its principal foreign trade is with China, with which for the teas of that country it used to exchange manufactured goods. Owing, however, to the frauds practised by the Moscow merchants, the Chinese will now only take gold and silver. Moscow is now the seat of the principal manufactures of Russia. There are, according to the latest statistics, in the government of Moscow 484 manufactories. Of these there are 135 of cotton, 117 silk, 30 cloth, 10 of chemical drugs and instruments, 7 of hats, 29 of leather, 1 sugar refinery, 6 distilleries of brandy, 8 of vinegar, 10 tallow foundries, 14 manufactories of tobacco, and some iron foundries, &c., &c.

The climate of Moscow is more healthy than that of most of the capitals of Europe. Its elevated position, the width of its streets, and the low elevation of its houses, allow a free circulation of air; but being unprotected by mountains, the winds are often very violent, and in the early summer vegetation frequently suffers severely from them. The summer is short, and would be very fine but for the sudden changes of weather to which it is subject, so that the winter is generally preferred; the sky is then of wonderful purity, and the respiration easier. The winter generally sets in about the middle of November, and lasts,

with occasional thaws of short duration, till the beginning of April; the change from winter to summer is very rapid. The mean temperature in winter is 4° below zero, Fahr. Vegetation is vigorous. The ordinary grain crops raised in the neighbourhood of Moscow are rye and wheat. The common vegetables of England thrive well in the gardens in its environs. The silver birch and pine attain the same height as in Great Britain. The commonest trees, in addition to those just mentioned, are the pine, the lilac, and a kind of acacia. The ivy cannot stand the severity of the climate, but is cultivated indoors as an exotic.

The origin of Moscow is wrapt in obscurity. The ordinary tradition is that it was founded by Youri Vladimirovitch Dolgorouki, in the middle of the twelfth century; the year given is 1147. The 700th anniversary of its foundation was kept in Moscow in the year 1847. The name of Moscow is supposed to have been taken from the River Moskva, on the banks of which it is built. The history for many centuries is little else than a record of fires, pestilences, sieges, and wars. Probably there is no other city in Europe which has suffered so frequently and so terribly from these calamities as the ancient capital of Russia. Its earliest traditions, alike with that last terrible event with which its name will be for ever associated in the mind of Europe, are of fire and sword. Moskva was for some time only an appendage of the principality of Vladimir, and shared the fate of other towns of that principality, being often sacked and burned by the Tartars. But it gradually grew into notice and importance; and about the middle of the thirteenth century history mentions a prince of Moscow, Michael, surnamed the Brave. The first prince of Moscow who obtained the title of Grand Prince was George Danilo-vitch, A.D. 1319. From this time the history of Moscow becomes the history of Russia. George was succeeded by his brother Ivan, surnamed Kalita, A.D. 1328. The Tartar khans were then the suzerains of Russia, and the Grand Princes received at their hands their investiture to the principedom. Ivan was distinguished for the craft and ability of his dealings with his Tartar masters. He persuaded the primate to remove his residence from Vladimir to Moscow, and thus make the latter city the capital of Russia. The primate's name was Peter; he built the cathedral of the Assumption, and was the first patron saint of Moscow.

The geographical position of Moscow was peculiarly favourable to the grand design entertained by Ivan of consolidation. It formed the central point of those districts which, lying in the neighbourhood of Vladimir, might be expected to form a union of interest with the grand principality; and that union being accomplished by the appointment of a Muscovite prince to the sovereignty, the long-desired concentration of means to free the country from its oppressors was at length obtained. Ivan surrounded Moscow with wooden walls, and rebuilt the Kremlin. He was succeeded by his son Simeon Ivanovitch, surnamed the Proud, A.D. 1339. He carried on his father's policy, but with less success, owing to the dissensions among the Russian princes which disturbed his reign. His grandson Demetrius (A.D. 1359) was a man of great courage and energy, and did much to strengthen and consolidate the Russian power. He surrounded Moscow with stone walls. The most memorable event in the reign of his son and successor Vassili (A.D. 1389), was the retreat of Tamerlane from the walls of Moscow. Russian chroniclers relate that it was owing to the intervention of the Virgin of Vladimir, and that it took place at the moment when the people of Moscow met her image, which at Vassili's order had been sent for from Vladimir. The Grand Prince built a monastery on the spot where the meeting took place, and gave it the name of *Stretenha*, or Place of Meeting. In the course, however, of the same reign Moscow was besieged by another army of Moguls, and Vassili was com-

Moscow.

History.

Moscow.

pelled to purchase peace by the sacrifice of his independence. The earlier part of his son Vassili's reign was full of disasters (A.D. 1425), but its termination was happier. He succeeded in freeing Moscow from the Tartar yoke, and consolidated his authority by decisive victories over the Novogorodians. His son Ivan, surnamed the Great (A.D. 1462), extended by conquest the Russian frontier to the Ural Mountains, made himself master of Novogorod, Tver, and Viatka, and formed an alliance with Maximilian, Prince of Austria, against Cassimir, King of Poland, and the Grand Duke of Lithuania. He was the first Grand Prince who took the title of Prince of all the Russias, and the name of Tzar, which is either a corruption of *Cæsar*, or more probably is of eastern origin, and signifies "king." He rebuilt the walls of the Kremlin, and in other respects greatly improved and added to the town. He was succeeded by his son Vassili (1505), who was equally great and prosperous with his father, and by the conquest of Pskoff, Seversky, and Smolensk, he made himself master of the whole of Russia. He was also successful in repelling an attack of the Crimean Tartars. Vassili received the ambassadors of Charles V. and Pope Clement who came to negotiate a treaty between Russia and Lithuania. They were accompanied by Herberstein, who has left an account of his visit to Moscow, written in Latin. The only part of Moscow at this period called the town was the Kremlin. The suburbs were occupied by mechanics. The houses were built at a distance from one another, and surrounded by gardens and corn-fields. The air was remarkably pure and healthy, and there were no endemic diseases. The number of houses was 4500, and the inhabitants 100,000; the shops were filled with the rich merchandise of Europe and Asia. Vassili died suddenly, after a short reign, leaving a son only three years old, A.D. 1543. This was Ivan the Terrible. The name was given him from the horrible crimes and deeds of blood which marked and disgraced the conduct of the latter part of his reign. In the beginning of his reign a terrible fire destroyed almost the whole of Moscow. The most memorable events of his reign were the conquest of Kasan, the taking of Astrachan, and the final destruction of the Tartar power in Russia.

His son and successor Fedor (A.D. 1581) reigned thirty years. The feebleness of his rule gave ample room for the exercise of faction and ambition; and his prime minister, Boris Goudanoff, having caused the death of the young Demetrius, the only direct heir to the throne, was, on the demise of Fedor, elected Tzar A.D. 1598. His son Fedor was dethroned by a monk who pretended to be the Demetrius whom Boris had caused to be put to death, and who obtained the aid of the Poles in support of his pretensions, A.D. 1605. The false Demetrius was driven from the throne and assassinated by Chouisk, who in his turn became Tzar. During his reign there were several pretenders to the throne, one of whom was supported by Sigismund, King of Poland, who took possession of Moscow and held it for two years. It was saved (A.D. 1610) by two Russians—Minim, a simple citizen merchant of Nishni Novogorod, and Prince Pojarsky, a nobleman who had been dangerously wounded by the Poles in a massacre of the Muscovites. They raised an army, and approaching Moscow, the town capitulated, thus relieving the inhabitants at the same time from the horrors of war and famine. Michael Fedorovitch, of the family of Romanoff, and by the female line descended from Ruric, the son of the patriarch of Russia, was then elected Tzar. His son and successor Alexis (A.D. 1645) was distinguished for his wise laws. Feodor, the son of Alexis, was succeeded by Peter the Great A.D. 1681.

The change of residence made by Peter from Moscow to St Petersburg did the former less injury than might have been expected. At first Peter made a law prohibiting,

under severe penalties, the building of houses in Moscow; but after twenty years the prohibition was withdrawn, and the sovereigns themselves vied with the great families of the empire in embellishing their ancient capital with new monuments of their munificence and power. Peter himself built a large military hospital; and other important buildings have since been erected—among others, a printing-press, a university with two colleges, a foundling hospital, and an arsenal. Katherine II., in particular, magnificently restored the principal cathedrals, and added new buildings; she also prohibited the erection of wooden houses in the Beloi Gorod. At the beginning of this century travellers described Moscow as immense, triangular, half wooden half stone, interspersed with gardens, dirty and badly paved, and in many points more resembling an overgrown village than the second capital of a great empire. The terrible catastrophe of 1812 has, however, made a vast difference in the external appearance of Moscow. On Wednesday, September 15, Napoleon took up his head-quarters in the Kremlin, and on the same day the fire broke out in the shops of the Kitai Gorod. The night of the 16th was illuminated by the fire of a general conflagration. The explosions, the balloons of flame which were seen falling from the tops of towers, showed the means which were being taken to spread the fire. A vast sea of flame illuminated the horizon for miles, and announced to the unhappy Muscovites who still lingered near the town that their homes no longer existed. The different quarters of the town took fire, burned, and disappeared all at once. Heaps of calcined and blackened stones indicated the spots where houses had stood. The silence of terror was only interrupted by a roaring like that of the waves of a stormy sea; this was produced by the wind, which, driving with violence the torrent of flame, hurried on far and wide the destroying element. From time to time whole buildings fell with a crash. Wherever the eye turned nothing could be seen but smoking ruins or devouring flames. Ever and anon was heard the mournful toll of a bell, which sounded like the signal passed between one and another agent in this work of destruction. In spite of the vigilance of the sentinels posted at the houses, the fire spread as if it had been driven by an invisible power. Although a great part of the town was built of wood, it took many days of general conflagration to consume it. At last, in most quarters of the town there were left so few traces of habitations that the streets could hardly be recognised. Human bodies half-burned, and the dead carcasses of horses, cows, and dogs, lay in the midst of the ruins. 30,800 houses, besides a great number of palaces, were reduced to ashes; scarcely 6000 buildings were left standing. Among these, however, was the Kremlin, which the fire did not touch. The private loss by the destruction of houses and their contents was calculated at not less than L.30,000,000 sterling, and this was probably under the mark. The question has been often asked, What hand set the torch to this great conflagration? Count Rostopchine, the then governor, to whom fame has commonly attributed it, repudiates the honour in a work entitled *La Vérité sur l'Incendie de Moscou*, published in Paris, 1828. The hypothesis that it was the act of the French is most unlikely. Napoleon could never have designed or permitted a calamity of which himself and his army were the first victims. The more probable theory is, that it was the act of the inhabitants themselves, and that Rostopchine set the example of patriotic devotedness. The desolation did not last long; Russian patriotism soon raised from its ashes their holy city, whose destruction had saved their country from foreign oppression. Subscriptions were opened in every part of the empire, and the liberality of the sovereign seconded the enthusiasm of his subjects. Moscow rose like a Phoenix from her ashes, but in greater beauty, and under a newer form. Her original character is not,

Moscow.

Moscow. however, entirely lost. The injuries which Napoleon wantonly inflicted on the Kremlin were restored in keeping with its peculiar style of architecture. It is to be regretted that the same taste has not been shown in other erections, both within that ancient fortress and in the rest of the city. The Kitai Gorod, however, is still in its principal features the Moscow of the seventeenth and eighteenth centuries; and the churches and monasteries, many of which escaped the ravages of the fire, preserve their distinctive character. Indeed, the whole city, though modernized, still preserves to a great degree its oriental appearance. The whitewashed houses with their painted roofs, the frequent gardens, the quaint-looking churches, in their general appearance,—save the Christian emblem which invariably surmounts their domes and cupolas, more like the Hindu pagoda or Mussulman mosque than a Christian place of worship,—strike the eye of the English traveller as rather Eastern than European. Those who have seen Moscow and Benares have been struck with the resemblance of the former to the holy city of North India. Moscow will always retain its place as the second capital of Russia. Its old associations, the sanctity which is attached to its name, the law according to which no emperor is invested with full imperial authority until he has received his crown within the ancient cathedral of the Assumption, will always secure for it the high rank it holds in this great empire. It may be added, that its importance in a commercial point of view is on the increase. The wealthier portion of the aristocracy are leaving it for the more courtly city of St Petersburg, but merchant princes are purchasing and inhabiting their palaces. It is the centre of the inland traffic of the country. Its wholesale houses supply the neighbouring governments with goods of foreign produce and manufacture; and in its own manufactories are made many of those articles for which there is the largest home demand and consumption.

The population of Moscow in 1855 was 380,000. The births were 9889; the deaths, 13,643; the marriages, 1725.

(G. T. C.)

Moscow, a government of European Russia, lying between 54. 40. and 56. 30. N. Lat., and between 34. 45. and 38. 11. E. Long., is bounded on the N. by the government of Tver, E. by Vladimir and Riazan, S. by Kaluga and Toola, and W. by Smolensk. Length, 140 miles; greatest breadth, 110; area, 12,683 square miles. The surface is low and undulating, broken by very few eminences, and these principally on the banks of the streams. The rivers and lakes are numerous, but are mostly of small size. The Volga traverses for a short distance the northern part of the government, and receives the Oka, with its affluents the Kliasma and the Moskva, all of which are navigable. The other streams, which are of smaller size, discharge their waters into one or other of these. The climate, like that of the other parts of Russia in the same latitude, is temperate, but more subject to extremes of heat and cold than in the west of Europe. The mean annual temperature is 40°, and the difference between summer and winter 47°·7. Though agriculture is the principal occupation of the people, and this government is one of the best cultivated in Russia, the fertility of the soil is not great; so that the produce of grain is not sufficient to supply the wants of the inhabitants. The quantity of cultivated land in the government of Moscow is about 3,089,600 acres; of meadowland, 1,307,000 acres; of wood, 3,592,000 acres; and of waste land, 384,151 acres. The amount of corn produced in 1849 was 22,306,729 bushels; and of potatoes, 3,475,264 bushels. Flax, hemp, and hops are also raised for home supply; and a large portion of the ground in the neighbourhood of Moscow is laid out in gardens and orchards, which supply that city with vegetables and fruits. The inhabitants are also employed to a

VOL. XV.

large extent in the rearing of cattle. In 1849 the government contained 294,267 horses, 279,742 horned cattle, 353,715 sheep, 41,023 swine, and 1128 goats. No metals are worked in Moscow; but granite in the form of boulders, freestone, limestone, potter's clay, &c., are found and made use of. Manufactures of cloth, silk, hats, leather, copper, glass, earthenware, &c., are carried on here; and the population is more actively employed, as well as more dense here than in any of the other governments of the empire. The value of the woollen goods manufactured in the government of Moscow is estimated at more than L.2,000,000, which is about one-half of the whole amount produced in the empire. The manufacture of silk in Russia has its chief seat in this government, and 1,260,000 lb. of raw material are consumed annually. Moscow is also one of the principal seats of the cotton manufacture. From the position of the country, its commerce is entirely internal, and is facilitated by excellent roads, and by the railway from St Petersburg to Moscow, which was completed in 1851, as well as by rivers and canals. The prevalent religion is that of the Greek Church; and the government forms the see of an archbishop. Pop. (1851) 1,348,041; estimated in 1857 at 1,526,000.

MOSEIRAH, an island in the Indian Ocean, off the S.E. coast of Arabia, between 20. 8. and 20. 44. N. Lat., and between 58. 37. and 58. 58. E. Long. It is about 38½ miles in length, and nowhere rises more than 600 feet above the sea. Parts of the surface are cultivated; and there are some copper mines, which were formerly worked by the Persians. The population is numerous, and the island is governed by two sheikhs, who seem to be mutually independent, but subject, at least nominally, to the Imam of Muscat.

MOSELLE, a department of France, lying between 48. 54. and 49. 34. N. Lat., and 5. 25. and 7. 40. E. Long. It is bounded on the N. by Belgium, Dutch Luxembourg, and Rhenish Prussia, E. by the palatinate and the department of Lower Rhine, S. by that of Meurthe, and W. by that of Meuse. Its length is 102 miles; its breadth, which varies very much, is on an average about 25 miles; and its area is 2350 square miles. The surface of the department is in general undulating, with a gradual slope towards the N.; while the eastern part is occupied by branches of the Vosges Mountains, and the western part by those of the Ardennes. None of the hills, however, rise above 650 feet in height; and they are well wooded on the top with timber, which is used for ship-building, and on the sides with fruit trees. The country is watered by the Moselle, from which it derives its name, and by its affluents, flowing generally towards the north. The Moselle is navigable in this department for 49 miles, and the Sarre for 23. The Chiers, a tributary of the Meuse, also traverses the N.W. corner of Moselle. The climate is for the most part mild, but colder and more severe in the hilly regions. The mineral resources of the department are considerable, consisting of iron, which is found in great abundance, building stone, sandstone, potter's clay, marl, and plaster of Paris. The soil of the valleys and slopes of the hills is very rich, and well cultivated; and improvements are being gradually introduced in the implements and methods of agriculture used in the department. Of its whole extent it has been calculated that there are 741,343 acres of arable land, 111,200 of meadows, 222,402 of wood, and 14,826 of waste land. Corn is raised in sufficient quantities to leave a considerable amount for exportation; and the principal kinds are oats, rye, and wheat; the two former of which are more suitable to the soil than the last. Besides these, peas, beans, millet, vetches, lentils, potatoes, beet-root, rape, turnips, hemp, flax, &c., are grown; but although the vine is cultivated in the department, the wines of Moselle are of inferior quality, and are chiefly

40

Moseirah
Moselle.

Moselle
||
Moser.

used for the manufacture of what is called champagne, for sale in Germany and Russia. Gardens are extensively and well cultivated, and many kinds of fruit are raised of an excellent quality. The horses of the department, amounting in number to 65,000, are of small size; the horned cattle, about 110,000, of an inferior breed; the sheep, about 180,000, yield bad wool; and the only animals of good breed are the pigs, amounting to 108,000, to the rearing of which considerable attention is paid. There are also many bees, which produce a large supply of honey. Game of various kinds is plentiful in the forests, and fish in the rivers. The manufactures of Moselle are numerous, consisting principally of iron-works, in which sheet iron, nails, cutlery, &c., are fabricated. Next in extent and importance to these are the glass-works and potteries. There are also manufactures of linen, paper, beer, tobacco, beet-root sugar, leather, hosiery, &c. A considerable trade is carried on in the exportation of the produce of the manufacturing and agricultural industry of the department. The capital is Metz, where there is a court of appeal for the department. Moselle also contains 4 civil tribunals, an academy, 2 grammar schools, a normal school for the department, and 900 elementary schools; besides other educational institutions. It is divided into 4 arrondissements, as follows:—

	Cantons.	Communes.	Pop. (1851).
Metz	9	223	169,472
Thionville	5	118	91,708
Briey	5	182	67,481
Sarreguemines.....	8	155	131,023
Total.....	27	628	459,684

The population of the department in 1856, however, was only 451,152.

MOSELLE (Germ. *Mosel*, Dutch *Moezel*, anc. *Mosella*), a river of Europe, rises in France, in the Vosges Mountains, at the S.E. corner of the department of Vosges, and flows in an irregular course for some distance N.W., and then nearly N., through the departments of Vosges, Meurthe, and Moselle. It then separates Dutch Luxembourg from Rhenish Prussia for a short distance; and finally, after crossing the latter country in a very winding course, generally N.E., it falls into the Rhine at Coblenz. For the greater part of its course this river flows in a narrow valley, bounded in some places by rocky mountains; but in the department of Moselle, from Metz as far as Sierck, the hills recede to some distance from the river, and inclose a wider plain. The largest of the tributaries of the Moselle enter it from the right,—namely, the Mosellette, the Vollogne, the Meurthe, the Seille, and the Sarre. Its tributaries from the left are the Madon, the Math, the Orne, the Sure, the Kyll, and the Elz; the first three being in France, and the others in Prussia. The Moselle occasionally overflows its banks, and causes great injury to the surrounding country. Its whole length is 320 miles, of which 182 are in France; and it is navigable as far as its confluence with the Meurthe, 210 miles from Coblenz. Above this point, however, it may be traversed by small boats for some distance; and timber is floated down the stream from very near its source. The soil through which it flows is very fertile, and the scenery on its banks is in many places of great beauty.

MOSER, JOHANN JACOB, a German writer on public law, and one of the most voluminous of modern authors, was born at Stuttgart in 1701. At the age of nineteen his acquirements raised him from the rank of a student to the dignity of professor extraordinary at the university of Tübingen. He was appointed a councillor at Stuttgart in 1726; and on the removal of the public administration from that city to Louisburg in the following year, the chair of law at Tübingen was conferred upon him. But

the impatient temper of Moser was ever apt to involve him in broils with his acquaintances. In course of time a misunderstanding with his colleagues induced him to resign his professorship. He was prevented by a similar cause from remaining longer than 1739 in the situation of director of the university of Frankfurt-on-the-Oder. Then retiring to the small town of Ebersdorf, he devoted his time to the composition of numerous works, and especially of his chief treatise, on the *Public Law of Germany*. His fastidious disposition, however, had not yet found its proper sphere. He left his retirement in 1747, and after remaining in the service of Hesse-Homburg for two years, he repaired to Hanau, and founded an academy for the instruction of the young nobility in public affairs. In 1751 the office of *landschaftsconsulent* in Stuttgart was conferred upon him. He was apprehended in 1759 on the suspicion of having written a memorial to the Duke; and he lay for five years in the fortress of Hohentwiel. On his release he abandoned public life, and spent the rest of his days in illustrating and explaining, by means of his writings and compilations, the laws and privileges of Germany. Moser died at Stuttgart in 1785. A list of his works, which amount to about 484, has been published by Meusel.

MOSES, the son of Amram and Jochebed, was born in the year 1571 before Christ. Pharaoh, King of Egypt, perceiving that the Hebrews had become a formidable nation, issued an edict commanding all the male children to be put to death. To avoid this cruel decree, Jochebed, the mother of Moses, having concealed her son for three months, at length made an ark or basket of bulrushes, daubed it with pitch, laid the child in it, and exposed him on the banks of the Nile. Thermuthis, the King's daughter, who happened to be walking by the river's side, perceived the floating cradle, commanded it to be brought to her, and being struck with the beauty of the child, determined to preserve his life. In three years afterwards the princess adopted him as her own son, called his name Moses, and caused him to be diligently instructed in all the learning of the Egyptians. But his father and mother, to whom he was restored by a fortunate accident, were at still greater pains to teach him the history and religion of his fathers. When in his fortieth year, Moses left the court of Pharaoh, and went to visit his countrymen the Hebrews, who groaned under the tyranny and oppression of their unfeeling masters. Having perceived an Egyptian smiting a Hebrew, he killed the Egyptian, and buried him in the sand. But he was obliged, in consequence of this murder, to fly into the land of Midian, where he married Zipporah, daughter of the priest Jethro, by whom he had two sons, Gershom and Eliezar. Here he lived forty years, during which time he employed himself in tending the flocks of his father-in-law. Having one day led his flock towards Mount Horeb, God appeared to him in the midst of a bush, which burned with fire, but was not consumed, and commanded him to go and deliver his brethren from their bondage. Moses at first refused to go, but was at length prevailed on by two miracles, which the Almighty wrought for his conviction. Upon his return to Egypt, he, together with his brother Aaron, went to the court of Pharaoh, and told him that God commanded him to let the Hebrews go to offer sacrifices in the deserts of Arabia. But the impious monarch disregarded this command, and caused the labour of the Israelites to be doubled. The messengers of the Almighty again returned to the King, and wrought a miracle in his sight, that they might move his heart, and induce him to let the people depart. Aaron having cast down his miraculous rod, it was immediately converted into a serpent; but the same thing being performed by the magicians, the King's heart was more and more hardened; and his obstipacy at last drew down the judgments of the Almighty upon his kingdom, which was

Moses.

Moses. afflicted with ten dreadful plagues. (See Bryant's *Observations on the Plagues inflicted on the Egyptians.*) These dreadful calamities at length moved the heart of the hardened Pharaoh, and he consented to allow the people of Israel to depart from his kingdom.

Profane authors who have spoken of Moses appear to have been in part acquainted with these mighty wonders. That he performed miracles has been allowed by many, by whom he was considered as a famous magician; and he could scarcely appear in any other light to men who did not acknowledge him as the messenger of the Almighty. Both Diodorus and Herodotus mention the distressed state to which Egypt was reduced by these terrible calamities. The Hebrews, amounting to the number of 600,000 men, without reckoning women and children, left Egypt on the 15th day of the month Nisan, which, in memory of this deliverance, was thenceforth reckoned the first month of their year. Scarcely had they reached the shore of the Red Sea, when Pharaoh with a powerful army set out in pursuit of them. On this occasion Moses stretched forth his rod upon the sea, and the waters thereof being divided, remained suspended on both sides till the Hebrews passed through dry-footed. The Egyptians determined to follow the same course; but God caused a violent wind to blow, which brought back the waters to their bed, and the whole army of Pharaoh perished. (See Wilkinson's *Manners and Customs of the Ancient Egyptians*, vol. i., c. 2.)

After the miraculous passage of the Red Sea, the army proceeded towards Sinai; and after suffering considerable privation, arrived at the foot of that mountain on the 3d day of the ninth month after their departure from Egypt. Moses having ascended several times into the mount, received the law from God in the midst of thunders and lightnings, and concluded the famous covenant between the Lord and the children of Israel. When he descended from Sinai, he found that the people had fallen into the idolatrous worship of the golden calf. The messenger of God, shocked at such ingratitude, broke in pieces the tables of the law which he carried in his hands, and put 23,000 of the transgressors to the sword. He afterwards re-ascended the mountain, and there obtained new tables of stone, upon which the law was inscribed.

Moses having dedicated the tabernacle, consecrated Aaron and his sons to be its ministers, and appointed the Levites to its service. He likewise gave various commandments concerning the worship of God and the political government of the Jews. This was a theocracy in the fullest extent of the word. God himself governed them immediately by means of his servant Moses, whom he had chosen to be the interpreter of his will to the people; and he required all the honours belonging to their king to be paid to himself. He dwelt in his tabernacle, which was situated in the middle of the camp, like a monarch in his palace; he gave answers to those who consulted him, and himself denounced punishment against the transgressors of his laws. This was properly the time of the theocracy, taken in its full extent; for God was not only considered as the divinity who formed the object of their religious worship, but as the sovereign to whom the honours of supreme majesty were paid. The case was nearly the same under Joshua, who, being filled with the spirit of Moses, undertook nothing without consulting God. Every measure, both of the leader and of the people, was regulated by the direction of the Almighty, who rewarded their fidelity and obedience by a series of miracles, victories, and successes. After Moses had regulated everything regarding the civil administration and the marching of the troops, he led the Israelites to the confines of Canaan, to the foot of Mount Nebo; and here the Lord commanded him to ascend into the mountain, whence he showed him the promised land, into which he was not permitted to enter. He im-

mediately afterwards yielded up the ghost, in the hundred and twentieth year of his age, and 1451 years before Christ. **Mosheim.**

Moses is believed to be the author of the first five books of the Old Testament, which go by the name of the *Pentateuch*, and which both Jews and Christians acknowledge to be inspired. The ninetyeth Psalm is also ascribed to him; and some allege that he was the author of the book of Job, but the arguments on this point are not very conclusive. Numerous traditions respecting this celebrated personage are to be met with among the ancient Jews and the later rabbinical writers. (See Philo, *Vita Mosis*, c. iii.; Josephus, *Antiq.* ii. 9; Bartolucci, *Bibliotheca Rabbinica*, iv. 115; also Milman's *History of the Jews*, vol. i., p. 61.) Among the Arabs also legends abound regarding him. (Hottinger, *Historia Orientalis*, p. 80.) Repeated mention is made of Moses in the Greek and Roman classics, but their accounts of him are generally distorted and fictitious. (See Meier, *Judaica, seu veterum Scriptorum profanorum de Rebus Judaicis Fragmenta*, Jena, 1832. Concerning the life of Moses, see Warburton's *Divine Legation of Moses*; Hess, *Geschichte Mosis*, 2 vols., Zurich, 1778; Niemeyer, *Charakteristik der Bibel*, vol. iii.)

MOSHEIM, JOHANN LORENZ VON, a celebrated ecclesiastical historian, was descended from a noble family, and was born at Lübeck in October 1694. He was educated in the Protestant religion; and from the gymnasium of his native place he was sent to study divinity at the university of Kiel. There, when he had scarcely attained the age of manhood, he was appointed to succeed Albert zum Felde as professor and first pastor. In this double office his talents found full scope. His lectures were pervaded by great erudition, controlled by delicate ingenuity and penetrating sagacity. He appeared to especial advantage in the pulpit. The style of his sermons, formed on the models of the great English and French preachers, was chaste, lucid, and graceful, and burned with a fervid and eloquent piety. Ere four years had passed, Mosheim had become famous in other countries, and was besieged with offers of preferment from several governments. Accepting the invitation of the Duke of Brunswick, he removed to the chair of theology at Helmstädt in 1723. Here, during the next four-and-twenty years, his fame continued steadily to increase. His eloquence, the moral graces of his character, and his skill in tuition, rendered him the favourite professor of the university. The publication of his *Institutionum Historie Ecclesiasticæ libri iv.*, in 2 vols. 12mo, 1726, and of numerous other works, extended his celebrity. The Duke of Brunswick appointed him Abbot of Marienthal and Michaelstein, and inspector-general of the schools in the duchy of Wolfenbüttel, and in the principality of Blankenburg. From foreign princes, and from several learned societies, he also received marks of distinction. All this eminence only served to bring into greater prominence his affable bearing, the gentle amiability of his disposition, and his consistent Christian practice. In 1747 Mosheim was promoted by George II. of Great Britain to the theological chair and the chancellorship of the university of Göttingen. His health was now beginning to yield under the intensity of his mental activity. Yet he continued to study, and to lecture on theology, for three hours every day, to audiences composed of men of every class and vocation. At length, worn out with labour, he died in September 1755. In the same year was published a new and enlarged edition of his *Institutes*. This work was translated into German by Von Einem and by I. R. Schlegel. There are two English versions,—that of Dr Maclaine, published in 1764; and that of Dr Murdock, published in 1832. The latter, which is by far the more correct, was revised and re-edited by Dr James Seaton Reid in 1848. The *Institutes* of Mosheim introduced a new era in the writing of ecclesiastical history. He

Moskonisi
||
Mosquito
Shore.

was among the first to separate historical facts from the rubbish among which they had been usually exhibited,—to refer to the characteristics of each separate age,—to trace clearly the mutual reaction between civil and ecclesiastical affairs,—and to use care and candour in narrating the controversies and broils of different sects. Yet his division of events into those *external* and those *internal*, and into those *prosperous* and those *calamitous*, is thoroughly contradictory to the true character of history. He also suffers the dignified neutrality of the historian to suppress completely that expression of sympathy with the good and the true which ought to be shown by every writer. The other work of Mosheim which is well known in this country is his *De Rebus Christianorum ante Constantinum Magnum Commentarii*, 4to, Helmstädt, 1753. An English translation of this treatise, begun in 1813, by R. S. Vidal, was completed and edited by Dr Murdock, in 2 vols. 8vo, New York, 1851.

MOSKONISI, an island of Asiatic Turkey, in the pashalic of Anatolia, is situated in the Gulf of Adramytti, in 39. 20. N. Lat., 26. 40. E. Long. It is about 4½ miles in length, and is joined to the mainland by a sandy isthmus. The surface is mountainous; and the island produces fruits and cotton, which are exported from the small port of Mosko, on the south coast.

MOSQUE, a temple or place of religious worship amongst the Mohammedans. All mosques are square buildings, generally constructed of stone. The Arabian and Syrian mosques have generally vast quadrangles surrounded with numerous columns, while those of the Turks are noted for the elegance of their cupolas. Before the chief gate there is a square court paved with white marble, and low galleries round it, the roof of which is supported by marble pillars. In these galleries the Mussulmans perform their ablutions before they go into the mosque. In each mosque there are a great number of lamps; and between these are suspended many crystal rings, ostrich eggs, and other curiosities, which, when the lamps are lighted, make a fine show. As it is not lawful to enter the mosque with the feet covered, the pavements are covered with pieces of stuff sewed together, each being wide enough to hold a row of men kneeling, sitting, or prostrate. The women are not allowed to enter the mosque, but remain in the porches without. About every mosque there are six high towers, called *minarets*, each of which has three little open galleries, one above another; these towers, as well as the mosques, are covered with lead, and adorned with gilding and other ornaments; and from them the people are summoned to prayers by certain officers appointed for the purpose, called *muezzins*. Most of the mosques have a kind of hospital belonging to them, in which travellers, of whatsoever religion they may be, are entertained three days. Each mosque has also a place called *tarbe*, which is the burying-place of its founders; within it there is a tomb six or seven feet long, covered with green velvet or satin; at the ends are two tapers, and round it several seats for those who read the Koran and offer up prayers for the souls of the deceased.

MOSQUITO SHORE, MOSQUITO COAST, and MOSQUITIA, are terms used to designate a portion of the eastern coast of Central America, on the Caribbean Sea. As geographical, and still more as political designations, they have been very vaguely applied to an extent of coast varying from 200 to 500 miles in length, and of indefinite breadth. It has at times been asserted that the Mosquito Shore embraced the entire coast of Central America between Cape Cameron or Honduras, near the port of Truxillo, in Lat. 16. N., Lon. 85. W., and Boca del Toro, in Chiriqui Lagoon, in Lat. 10. N., Lon. 82. W., a coast-line of not less than 800 statute miles. Amongst geographers generally, however, the Mosquito Shore was understood only as comprehending the coast lying between Cape Gracias á Dios

and Bluefields Lagoon, including the latter; that is to say, between 12. and 15. N. Lat., a distance of about 250 miles.

Mosquito
Shore.

This coast was discovered by Columbus in his fourth voyage, in 1502. He sailed along its entire length, stopping at various points to investigate the country, and ascertain the character of the inhabitants. He gave it the name of *Cariay*; and it was accurately characterized by one of his companions, Porras, as “una tierra muy baja,” a very low land. His son, Fernando Columbus, described the inhabitants as “almost Negroes in colour, bestial, going naked; in all respects very rude, eating human flesh, and devouring their fish raw as they happened to catch them.” The language of the chroniclers, however, warrants us in believing that this description applied only to the Indians of the immediate sea-coast, and that those of the interior were then, as they still remain, a different people, with a distinct language. A grant of the entire coast, from Cape Gracias to the Gulf of Darien, was made to Diego de Nicuesa, for purposes of colonization, within ten years after its discovery; but the expedition which he fitted out to carry his grant into effect was wrecked at the mouth of the Cape or Wanks River.

Although the attention of Spain was too much absorbed with the other parts of her immense empire in America to enable her to devote much care to this comparatively unattractive shore, nevertheless her missionaries, with the characteristic zeal of that early period, made various attempts to found establishments at Cape Gracias á Dios, and probably at other points on the coast. But the resources of the country were too few for their support, and the Indians too debased and savage to receive the teachings of Christianity.

In the year 1576 this coast was conveyed by royal cedula to the “illustrious Señor Licenciado Diego Garcia de Palacio, Oidor of the Royal Audiencia of Guatemala,” and “Captain Diego Lopez, resident of the port of Truxillo,” in Honduras, by them to be colonized and governed under certain explicit regulations.

It does not appear that Palacio took any action under his grant, and the coast remained in its primitive condition until the era of the bucaniers, who obtained practical control of the sea of the Antilles about the middle of the seventeenth century. The intricate bogs, creeks, and rivers of this coast furnished admirable places of concealment and refuge for the small and swift vessels in which these freebooters roved the seas. They had establishments at Cape Gracias and Bluefields, whence they darted out like hawks on the galleons that sailed from Nombre de Dios and Carthage, laden with the riches of Peru. Indeed, Bluefields, the so-called capital of the Mosquito kingdom, derives its name from *Bleevelt*, a noted Dutch pirate, who had his rendezvous in the bay of the same name. In like manner, it is alleged, was the name of Wallace, a Scotch sea-rover, transformed, by Spanish pronunciation, to Balice, and finally to Belize.

The piratical establishment at Cape Gracias seems to have been not only the principal one on the Mosquito Shore, but in the entire Caribbean Sea. It is oftenest mentioned in the narratives which the pirates have left us of their wild and bloody adventures. Here they met, by common consent, to divide their booty, and agree upon new expeditions. Their relations with the Indians seem to have been friendly; the pirates, nevertheless, from their superior intelligence and numbers, taking the position of masters.

The accounts of the inhabitants of the coast, as given by the bucaniers, coincide with those left to us by Columbus and his companions. They are described as extremely indolent, “wandering up and down, without knowing or caring so much as to keep their bodies from the rain, except by a few palm leaves,” with “no other

Mosquito
Shore.

clothes than an apron tied around their middle," armed with spears "pointed with the teeth of crocodiles," and living chiefly on bananas, wild fruits, and fish.

At a very early period the Indians on the Mosquito Shore seem to have received a large infusion of Negro blood, which has come to be predominant among the existing inhabitants.

Many of the bucaniers were Englishmen, and all had relations more or less intimate with Jamaica, where, at that period of lax public morality, they often shared their profits with the authorities in return for such indulgences and assistance as the latter were able to afford. Indeed, it is alleged that the governors of the island were often partners in the enterprises of the freebooters. But when the protracted wars with Spain, which favoured this state of things, were brought to a close, it became no longer prudent to connive at bucaniering; and as a kind of intercourse had sprung up with the Mosquito Shore, they conceived the idea of obtaining possession of it on behalf of the British crown. Various plans to this end, drawn up by different individuals, were at this period presented to the royal government, and by it referred to the governors of Jamaica.

But the governors of that island had themselves already taken the initiative. As early as 1687 one of the Mosquito headmen or chiefs had been carried to Jamaica for the purpose of placing his country under the protection of the British crown. Sir Hans Sloane has left us an account of how, having escaped from his keepers, "he pulled off the European clothes his friends had put on, and climbed to the top of a tree." It seems, nevertheless, that he received "a cocked hat and a ridiculous piece of writing," which, according to Jeffreys, was a commission as king, "given by his Grace the Duke of Albemarle, under the seal of the island. Robert Hodgson, writing about 1740, affirms, not only "that the king has his commission or patent for being called so from the governor of Jamaica," but also that "all the other chief people have commissions (as admirals and captains) from his Majesty's superintendent."

In 1740 it would appear that an attempt was made to obtain an absolute cession of the coast to the British crown. In that year Trelawney, governor of Jamaica, wrote to the Duke of Newcastle, suggesting the expediency of rousing the Mosquito Indians against the Spaniards, and proposing an immediate occupation of the coast. He represented that there were about one hundred Englishmen there, "mostly such as could live nowhere else," who might be brought together, reinforced, and, by the help of the Mosquitos, finally induce the other Indians to revolt, "and thus spread the insurrection from one part to another, till it should become general over the Indies, and drive the Spaniards entirely out."

In pursuance of this scheme, Governor Trelawney commissioned one Robert Hodgson to proceed to the Shore, where he arrived, laden with presents, on the 8th of April 1740. He succeeded in getting together some of the head men, including "King Edward" ("Admiral Dilly," "General Hobby," and "Captain Jumper," being unavoidably absent), and on the 16th of the month "proceeded to explain to them, that as they had long acknowledged themselves subjects of Great Britain, the governor of Jamaica had sent me to take possession of their country in his Majesty's name,—then asked if they had anything to object?" No objection being made, Hodgson proceeds:—"I immediately set up the standard, and reducing what I had said into articles, I asked them, both jointly and separately, if they approved, and would abide by them? They unanimously declared they would." Hodgson inclosed the articles to Governor Trelawney, and adds, "As to the king he is very young, I believe not twenty, and is not much observed; but were he to be in England or Jamaica a while, 'tis thought he would make a hopeful monarch enough."

Mosquito
Shore.

Previously to the mission of Hodgson, on the 28th of October 1739, the Spanish ambassador in London had made complaints that the incursions of the Sambos and Indians of the Mosquito Shore, on the adjacent Spanish settlements, were "at the instigation, and under the protection, of the English of Jamaica, who have a commerce with them, and give them in exchange for the captive Indians, whom they purchase for slaves, fire-arms, powder, shot, and other goods, contrary to the natural rights of these people."

And here it may be mentioned, that subsequent to the era of the bucaniers, during the whole of the eighteenth century, and even as late as 1820, it was the constant practice of the Mosquitos to make forays into the territories of the Woolwas, Cookras, Tonglas, and other pure Indian tribes lying between the coast and the Spanish settlements, for the capture of prisoners, to be sold as slaves to the traders from Jamaica. The scandal finally attracted the attention of Parliament, and was made the subject of a commission of inquiry, which reported, July 10, 1828, recommending the liberation, under certain conditions, of the Indians thus enslaved. From this cause has sprung that settled hostility which still exists between the Sambo-Mosquitos and their Indian neighbours of the interior, and which, until recently at least, led the latter to punish with death any intercourse between their people and the hated Mosquitos.

The "cession" of the Mosquito Shore, procured, as we have seen, by Hodgson, was followed up by occupation. Several Jamaica planters settled there; and Hodgson, in reward for his services, was placed in charge of the new establishment, with the title of "Superintendent of the Mosquito Shore," dependent on the governor of Jamaica.

In 1744 an order was issued in council, despatching a certain number of troops from Jamaica to the Mosquito Shore; and in 1748 another order for sending a supply of ordnance to the "new settlements" established there. At this time everything indicated the purpose of a permanent occupation of the country on behalf of the crown. The Spaniards, alarmed at these encroachments, as they regarded them, were loud in their remonstrances, and in 1750–51 threatened a forcible expulsion of the settlers; whereupon Governor Trelawney instructed Hodgson to represent to them, that "the object of keeping a superintendent amongst the Indians was to restrain them in their hostilities against the Spaniards." The latter were deceived, or from motives of policy accepted the explanation, and even went so far as to confer on Hodgson the title of Colonel for the services which he professed to have rendered them.

It was not long, however, before the settlers on the Shore discovered that the Spanish governors of the adjacent provinces of Honduras, Nicaragua, and Guatemala, were making formidable preparations for their forcible destruction. In their alarm they applied to Governor Knowles, who had succeeded Trelawney in Jamaica, and who at once opened a correspondence with the captain-general of Guatemala, for a suspension of hostilities, until he could hear from England—whither he wrote, that the whole Mosquito affair was "a job," and that if Hodgson were not checked or recalled, "he would involve the nation in difficulties;" and that, between Spanish and English pretensions, "the Indians were so perplexed that they did not know what part to take." In fact, a little later, a number of the Mosquito chiefs went to Guatemala, and there resolved to take up arms against the English; but it does not appear that any decided acts of hostility were committed by them.

These events did not escape the notice of Spain, and were among the causes which led to the rupture, terminated by the treaty of Paris in 1763, by which Great Britain agreed to demolish all the fortifications which she had erected, not only in the Bay of Honduras, but in "other

Mosquito
Shore.

places in the territory of Spain in that part of the world." It would seem that the Spanish crown was not satisfied with the conduct of Great Britain under these provisions, which were therefore revived, and made more explicit and stringent by the subsequent treaty of 1783, which stipulated that all the English settlers on the Spanish continent should retire within a district defined in the treaty. Nevertheless, relations were still kept up with the coast, and led to severe reclamations on the part of Spain. These were only settled by the supplementary treaty of 1786, which provided that his Britannic Majesty's subjects and other colonists, who have enjoyed the protection of England, shall evacuate the country of the Mosquitos, as well as the continent in general, and the islands adjacent, without exception, situated beyond the line described in the treaty.

By the 14th article of this treaty, "His Catholic Majesty, prompted solely by motives of humanity, promises to the King of England that he will not exercise any severity against the Mosquitos inhabiting in part the countries which are to be evacuated, in virtue of the present convention, on account of any connections which may have subsisted between the said Indians and the English; and his Britannic Majesty, on his part, will strictly prohibit all his subjects from furnishing arms or warlike stores to the Indians, &c."

These provisions met with serious opposition, and a motion was made in the House of Lords, "that the terms of the convention with Spain, signed in July 1786, did not meet the favourable opinion of this House." The motion was negatived; and, in the words of Macgregor, "with the most painful reluctance, and only in obedience to positive orders, the British settlers slowly and discontentedly left their plantations."

From 1786 forward, Great Britain ceased to hold any open relations with the Mosquito Indians, until the decline of the power of Spain and the loss of her American possessions. In the interval the governors of the provinces of Central America had attempted, but with poor success, to make permanent establishments on the Shore, at Cape Gracias and Bluefields. They, however, erected a fort at the mouth of the River San Juan, for the protection of the port of the same name, which was made a port of entry by royal cedula in 1796.

The stringent provisions of the convention of 1786 were revived and confirmed by an additional article to the treaty of Madrid of August 28, 1814. Meantime the continental war withdrew all attention from the Mosquito Shore, which passed entirely out of official view. A few of the old settlers nevertheless remained on the coast, and a commerce in tortoise-shells, deer-skins, and slaves, was kept up with Jamaica.

Roberts, who was on the coast in pursuit of his avocation as trader about the year 1820, has given a very faithful account of the Mosquitos and their political condition at that period. He speaks of a personage called "King," a young man who had been in Jamaica, "where he was semi-educated," and whose authority, if not openly disputed, was divided with sundry chiefs, among whom a "Governor Clementi" was most important. This "king" is described by Macgregor as having "combined the bad qualities of the European and Creole with the vicious propensities of the Sambo, and the capriciousness of the Indian." He was killed in a drunken brawl in 1824, and was succeeded by his half-brother Robert—who, however, was found to be too greatly in the Spanish interest to suit the trading Warwicks of Jamaica, and was accordingly deposed in favour of a Sambo of quite a different family, who received the name of George Frederick. What became of this potentate does not clearly appear from the Mosquito chronicles; he either died or was dropped for another Sambo, called Robert Charles Frederick.

Robert Charles Frederick was taken to the settlement of

Belize or British Honduras, and was there duly crowned on the 23d of April 1825. The king was dressed for the occasion in a British major's uniform, and so manifested his admiration for his finery as to impart a ludicrous character to the whole ceremony. Moved by liberal appliances of rum, in the exercise of royal liberality he made extensive grants of lands to his trading friends, which in some instances carried with them the rights of absolute sovereignty. When these proceedings came to the ears of the superintendent of Belize and of the governor of Jamaica, they excited considerable alarm, and an agent was sent to the shore, instructed to disallow the grants in question.

A vessel of war was sent down from Belize to carry Robert Charles Frederick away from the too powerful influences of rum and gay cottons; and he was accordingly taken to Belize, and placed beneath the eye of the superintendent of that establishment. His royal nature, however, rebelled against restraint; he gradually pined away and died; but not until he had affixed "his x mark" to a document styled "a will," in which it was provided that the affairs of his kingdom should be administered by Colonel Macdonald, superintendent of Belize, as regent, during the minority of his heir; that Macdonald should be guardian of his children; and that, in view of the spiritual wants of his subjects, "the United Church of England and Ireland shall be the established religion of the Mosquito nation for ever."

This will bears date February 1840, just one century after Hodgson had obtained the "cession" of the Shore to the British crown. One of the first acts of Macdonald was the appointment of Patrick Walker, his private secretary, to reside on the Mosquito Shore, and take charge and guardianship of the scions of the royal house. Walker at once took up his residence in Bluefields, and having organized a council of government, soon fell into a dispute with the neighbouring Central American states on the question of boundaries.

Aroused and alarmed by the proceedings of Walker, and ignorant as to whether the salic law was recognised in Mosquitia (the name now given to the country), they procured from the eldest child of Robert Charles Frederick, namely, the "Princess Ines Ann Frederick," on the 28th of October 1847, a distinct recognition of the authority of Nicaragua over the Shore, and a queenly command to all interloping foreigners to leave the country.

The restless mind of Walker, who imagined himself a second Hastings, soon forced the quarrel beyond the consular offices of the Crown into the cabinets of Downing Street; and in the same year (1847), when the recreant Mosquito princess passed over to the Nicaraguan interests, he had succeeded in obtaining from Lord Palmerston an instruction to all the diplomatic and other agents of the Crown in Central America and the adjacent countries, requiring them to report "what authentic information they could obtain as to the boundaries claimed by the King of Mosquito;" and also "what, in your opinion, is the line of boundary which Her Majesty's government should insist upon as essential for the security and wellbeing of the Mosquito state." This was soon followed up by a despatch to the same agents, instructing them to inform the states adjacent to the Mosquito Shore, that "Her Majesty's government could not view with indifference any encroachment on the rights or territories of the King of Mosquito, which is under the protection of the British crown." Mr Walker, and Mr Chatfield, Her Majesty's consul-general in Guatemala, both reported that the "well-being of the Mosquito state required an assertion of the rights of the Mosquito king over the entire eastern coast of Central America, from Cape Honduras to Chiriqui Lagoon, an extent of 600 miles; yet his lordship limited himself to the opinion, that the "rights of the King of Mosquito should be maintained, as extending from Cape Honduras down to the mouth of the River San Juan." It may readily be pre-

Mosquito
Shore.

Mosquito
Shore.

sumed that the instruction to communicate the views of Her Majesty's government upon this point to the Central American States, was promptly complied with by Her Majesty's agents, and Mr Chatfield took the latitude of adding, that these limits were to be accepted "without prejudice to the right of the Mosquito king to any territory *south* of the River San Juan."

In the meantime, influenced by Walker's representations, Macdonald, who was a man of action rather than of words, paid a visit to the Shore in a vessel of war, entered the port of San Juan, and, after some mild proceedings, seized the collector, Quijano, carried him off, and finally landed him alone at a desolate point on the coast several hundred miles from the port. The only immediate consequences of this proceeding were vehement reclamations on the part of the Central American States, who now asserted their rights over San Juan in the most positive terms.

Macdonald's conduct in this, as in some other matters, does not seem to have been approved by the home government; but in the month of January 1848 two British vessels of war appeared in the harbour of San Juan, and occupied it without resistance, replacing the Nicaraguan officials by Englishmen, acting as servants of the King of Mosquito. This done, they sailed away; but no sooner did the intelligence of the event reach the interior, than the Nicaraguan government embarked a small force and re-occupied the port, sending the new officials as prisoners to the capital. The British forces, considerably strengthened, thereupon returned, and the Nicaraguans, unable to oppose them, retired up the River San Juan, and erected some rude fortifications on its banks. They were followed by an English detachment, and finally, March 12, 1848, routed with great loss. Walker, who accompanied the expedition, was either killed or drowned during the engagement. Hostilities were further prosecuted, until the Nicaraguans, powerless against the strength of Great Britain, consented to an armistice, which provided that they should not disturb San Juan, or attempt to re-occupy the port, pending the negotiations which it was foreseen would follow on these events. All efforts, however, to induce them to relinquish their claims of sovereignty over the port, or, even by implication, to recognise the Mosquito king, were unsuccessful. A consul-general of Great Britain was at once appointed to the Mosquito Shore, who took up his residence at San Juan, where, with the support of a number of policemen from Jamaica, and the almost constant presence of a vessel of war in the harbour, he assumed and exercised all the functions of government, judicial and executive.

The government of Nicaragua now addressed an exposition and appeal to the nations of Europe, and a particular and fervent one to the United States, for their friendly interference in behalf of what they claimed as their clear territorial rights and violated sovereignty. The American people and government were not slow to believe that the seizure of San Juan was an act of violence on the rights of a weak power, directed to obtaining control of the transit between the seas; as the line through Nicaragua, by way of the River San Juan and the Nicaraguan lakes, had long been regarded as affording the best, if not the only, route for a ship canal between the Atlantic and the Pacific Oceans. The recent acquisition of California also, and the sudden tide of emigration that took place to that country, rendered of importance to them every point where the isthmus could be traversed. The very first act of General Taylor, flushed from the fields of his Mexican victories, and carried almost by acclamation into the presidential chair, was the appointment of a diplomatic agent in Central America, invested with extensive powers, and instructed to look closely after the interests of the United States. Hardly had this agent reached his post, when a detachment of the British squadron in the Pacific, having on board Her Majesty's

consul-general at Guatemala, made its appearance in the magnificent Bay of Fonseca, and forcibly took possession of the fine islands commanding it in the name and on behalf of the British crown, by way of enforcing some claims for indemnity to British subjects against the states of Honduras and San Salvador. And as, in the speculations on the questions of an inter-oceanic canal, this bay had come to be regarded as offering the best conditions for the western terminus of such a work, precisely as San Juan was assumed to offer the same for its eastern terminus, this seizure was construed to be only an additional step in the settled policy of Great Britain to obtain control, if not absolute possession, of the highway between the seas.

The government of Honduras having obtained an intimation of the contemplated occupation of the Bay of Fonseca, resorted to the expedient of making a cession to the United States of the islands commanding it belonging to that state. Mr Squier, the American representative, accepted the cession on behalf of his government, which thus was made a party to the disputes between Great Britain and the Central American States. The seizure having taken place, regardless of the previous cession, an independent question was raised between the British and American cabinets, which seemed to threaten an open rupture, but which had the really beneficial effect of directing the serious attention of both governments to the necessity of settling the principles which should govern the policy of both as regarded the isthmus states, and especially as regarded that inter-oceanic highway to which circumstances had given a new importance. As soon as a knowledge of the seizure reached the United States, Mr Clayton, secretary of state, sent a despatch to Mr Lawrence, American minister in London (dated December 29, 1849), which the latter was desired to place before the British government. This despatch set forth that "the United States had no political designs in Central America," and that its interest in that country was confined to securing through it a free route of transit between the seas, which route it was declared to be the purpose of the United States "to protect, with the consent of the states through which it might pass." In conclusion, Mr Clayton directed Mr Lawrence to urge on the British government to disavow the seizure of the Bay of Fonseca, and to represent that if the act were not disavowed, the treaty of cession by which Honduras conveyed the only important positions in the bay to the United States, "would be submitted to the Senate for ratification without delay."

As already said, the serious attention of both governments, as well as of the people of both countries, having been thus arrested, public opinion, equally with common sense, dictated that an understanding should be reached, which should not only avert the possibility of a collision on these questions, but which should best subserve the wants of trade and commerce across the isthmus. It is not necessary to trace the progress of the negotiations which were now opened, and which, in the month of April, subsequent to the date of the despatch above alluded to, resulted in the signature of a special convention between the United States and Great Britain, known as the "Clayton-Bulwer Treaty," defining the policy of both regarding Central America, and giving a joint guarantee to such routes of inter-oceanic communication as might be opened "by canal or railway" through its territories.

A radical defect with this convention was its ambiguity on the subject of the Mosquito protectorate, and disputes arose as to its intent and meaning before the signatures were fairly dry on the parchment. On the one hand, it was claimed that the convention recognised and confirmed the protectorate of Great Britain; on the other, that it deprived it of all vitality, and reduced it to a shadow, and that the ambiguity of the convention was studied and

Mosquito
Shore.

Mosquito
Shore.

intentional, to enable Great Britain to retire gracefully from a false position.

While this new dispute was increasing in warmth, circumstances were fast working out a practical solution. An American company, acting under a charter from Nicaragua, had opened a route of transit for passengers through that state, commencing at San Juan, which rapidly filled up with emigrants from the United States. They soon became numerically predominant; and after some ungraceful attempts to proceed with reference to the alleged Mosquito authority, finally met in a primary capacity, and organised an independent local government, composed chiefly of Americans. The British protectorate, so far as San Juan was concerned, expired with an attempt on the part of the commander of one of Her Majesty's vessels of war, more zealous than discreet, to compel one of the transit steamers to pay certain port charges to his Mosquito majesty. The act was disavowed by the government, and San Juan remained, under the direct government of its own people, practically a free city; and as such, looking to its position, it should continue. Its prosperity was much retarded by a dispute with the adventurers into whose hands the transit had fallen, producing an irritation of feeling which resulted in certain alleged insults on the part of the town to an American diplomatic agent, whose belligerent tendencies led him to interfere in matters quite beyond the sphere of his duties. An American vessel of war was sent to inquire into the circumstances of the case. Her commander, acting under improper influences, assumed a most offensive and hostile attitude towards the town, and made various arrogant demands which were not complied with; whereupon he bombarded the place, and, landing a force of marines, burned it to the ground. The annals of this century furnish no parallel to this wanton and cruel procedure, and it stands a lasting disgrace and infamy to all concerned. It is certain that no such act was contemplated by the American government; but as it retained the delinquent officer in its service, and did not formally disavow the deed, it must be held to share the odium consequent upon it. Previously to this event, an effort had been made to adjust the Mosquito question, on the part of Mr Webster, secretary of state, and Mr Crampton, British representative in Washington. A *projet* was agreed upon, assigning a defined territory to the Mosquito Indians, and surrendering the port of San Juan (then called Greytown) to Nicaragua, on condition of certain annual payments to the Mosquito King. A joint English and American commission was sent to Central America to procure the assent of the adjacent states to the arrangement. Costa Rica, after some hesitation, acceded to the plan, but Nicaragua refused her assent; and the terms of the *projet* becoming known in England and the United States, they were found to be distasteful to the people of both countries. In America it was contended that no rights beyond those of occupancy could be acceded to any of the aboriginal tribes of the continent without violation of the leading principle on which the settlement of the continent had been effected, nor without danger to existing territorial rights. Some of the provisions of the Webster-Crampton *projet* were revived, in a convention signed by Lord Clarendon and Mr Dallas, American minister in London, in the autumn of 1856. The limits of the district assigned to the Mosquito Indians, however, were much more circumscribed; the port of San Juan was constituted a free port; and provisions recognising a Mosquito sovereignty, in a political sense, carefully excluded. This convention was ratified, with some slight modifications, by the United States Senate, but failed, in consequence of the non-exchange of ratifications within the time specified in the convention itself. The principles of this convention are no doubt those which will ultimately

prevail, and offer the only rational solution of the vexed Mosquito question. A better understanding of the mutual rights and duties of Great Britain and the United States on the American continent is fast removing every obstacle to an amicable adjustment of this and analogous differences.

The final solution of the question will no doubt be hastened and facilitated by the convention of August 27, 1856, between Great Britain and Honduras, wherein the territorial rights of the latter state are recognised over the coast between Cape Gracias and Cape Honduras, with the reservation of the right of occupancy to the Indians within a district of reasonable extent, to be fixed by a joint commission of the two governments. Such is the present political state of the Mosquito Shore.

As regards the Mosquitos themselves, little need be said, except that they are a hybrid race, coming rather under the denomination of Sambos than Indians. The Valiente, Rama, Cookra, Woolwa, Tongla, and Paya or Poyas Indians, who are sometimes claimed as Mosquitos, are quite independent of them, and generally hold a hostile attitude towards them. Some of these tribes, in whole or in part, recognise the rule of the adjacent Central American States, and many of their villages profess the Roman Catholic religion. Exclusive of these Indian tribes, the population of the Mosquito Shore is exceedingly small, certainly not exceeding 2000 souls. Colonel Hodgson (son of the Robert Hodgson elsewhere referred to), who wrote in 1757, estimates the population at "not above 7000;" and a MS. Spanish map of the date of 1777, purporting to be copied from an English original, gives "houses of whites, 17; of Mestizos, 13: number of whites, 28; Mestizos, 27; slaves, 252; Mosquito Indians, 182; Mosquito Sambos, 230;—total, 719." George Chalmers, secretary of the Board of Trade, in 1787, drew up a series of notes on the Mosquito Shore for the use of the Board, in which he observes:—"The present number of the Mosquito Indians is unknown. It happened among them probably, as among the North American Indians, that they declined in numbers and degenerated in spirit as the white people settled among them. Like the Caribs of San Domingo, they consist of three distinct races—the aborigines, the descendants of certain African Negroes wrecked on the coast, and a generation containing the blood of both. If the Spaniards earnestly desired to destroy them, they could not, I think, make a very vigorous resistance." The "Commissioners of Legal Inquiry in the case of the Indians of Honduras, 1828," describe the Mosquito Indians as "a barbarous and cruel people, in the lowest state of civilization—hostile to the other Indian nations, who are a mild, timid, and peaceful race." When Colonel Hodgson wrote, it appears that the inhabitants of the coast were not more homogeneous politically than in blood. He says of them, that then (1757) they were "not so properly a single state as three united, each independent of the others."

"1. Those who inhabit the southern extremity till Bragman's, and are mostly the original Indians; their head man is called *Governor*.

"2. Those who extend to about Little Black River, and are mostly Sambos; their chief is called *King*.

"3. Those westward, who are Indians and Sambos mixed; their head man is called *General*. The power of these three head men is nearly equal, with a small difference in favour of the king, who is a little supported by the whites for the sake of his name. The king has his commission or patent for being called so from the governor of Jamaica."

Whatever may have been the former numbers of the Mosquitos, there can be no doubt of the fact, that they are every day becoming fewer under the combined effects of drunkenness and disease. Upon the north, the Caribs, originally from St Vincent, are gradually encroaching on the Sambo Mosquitos, and crowding them down the coast, where their principal establishments are confined to Cape

Mosquito
Shore.

Mosquito
Shore.

Gracias, Sandy Bay, Rio Grande, Prinzapulka, Pearl Key, and Bluefields. In character and habits they remain much the same as when described by the pirates, living chiefly by fishing, and having little trade except in tortoise-shells and sarsaparilla. They are without any form of religion, but believe in a certain spirit of the water called *Lewire*, and an evil spirit named *Wulasha*, who consumes the bodies of the dead. They have great faith in a class of sorcerers, who combine the characters of the medicine-men of the North American Indians, and the obi-men of Africa, called *Sukias*, whose authority is often greater than that of the most powerful chief. These pretend to cure diseases by incantations and rude jugglery, directed chiefly to appeasing *Wulasha*, who shares in the reward of the *Sukias*.

The huts of the Mosquitos are mere thatched sheds of palmetto or cahoon leaves, about 6 feet high to the eaves, and projecting 3 or 4 feet beyond the line of posts. Some of the better ones are inclosed with a stockade or fence of palmetto stalks, having the entrance in the gable. The men sleep on the sand floor, or in hammocks, and the women on a rude frame-work of canes, raised a few feet above the ground. Their arts are confined to making *pit-pans*, long, flat-bottomed canoes for use in the rivers and lagoons; and *dories*, or large canoes for coasting on the sea. They also make harpoons and implements for fishing, and manufacture a kind of cloth, or *tappa*, from the inner bark of the *ule* or caoutchouc tree. In language they differ wholly from the neighbouring Indians, so that they are unable to communicate with them except through interpreters. From their long intercourse with the English, they have adopted many English words, which, however, are pronounced in a very broken manner, constituting a kind of jargon. Their own language is not deficient in euphony, although defective in its grammar. It has no article, definite or indefinite, but the numeral adjective *kumi* (one) is used whenever the idea of number is prominent. The adjective follows the noun, as do also the numerals. All nouns are understood to be masculine, unless qualified by the word *maisen*, woman or female. The pronouns are twelve in number, but have neither gender nor number, both of which must be inferred from the connections in which they are used. The verbs have mood, tense, and person, but are wanting in number.

The geography of the Mosquito territory is very little known. Upon the coast, however, there are several harbours of fair capacity, and some positions capable of easy settlement. Bluefields Lagoon is a considerable body of water, between 30 and 40 miles in length, and almost completely land-locked. It has a bar at its entrance, but within the bar it has from 4 to 6 fathoms. The great river Escondido, and several small streams, flow into it. On the south bank of this river is situated the town of Bluefields, the residence of the King and his English guardian. It contains nearly 500 inhabitants, including about 50 whites. 30 miles to the northward of Bluefields is Pearl Key Lagoon, affording a tolerable harbour for small vessels. A considerable river, the Wawashaan, falls into this lagoon. Still 30 miles to the northward, a large stream, the Rio Grande, flows into the sea. Its mouth is obstructed by a dangerous bar; but when this is passed, it is said that the river may be navigated for the distance of a 100 miles inland. Further to the northward are the Prinzapulka, Tongla, Brackman, Wava, Duckwara, and other considerable streams. Next in order is the Rio Wanks, the longest, if not the largest river in Central America, which reaches the sea at Cape Gracias a Dios. Towards their sources, amongst the mountains of Honduras and Nicaragua, all these streams are rough and rapid; but as they approach the ocean they lose their turbulent character, and flow majestically into the sea. During the seasons of the rains they usually overflow their banks, and, with the numerous creeks

and lagoons, constitute a net-work of lakes parallel to the sea-coast, which permit interior navigation all the way from Bluefields Lagoon to Cape Gracias. The climate of the coast is moist, hotter than the interior, and not so salubrious, although in the latter respect entitled to rank equally high with the West Indian Islands generally. The greater part of the soil is fertile, and capable of producing in abundance cotton, sugar, rice, indigo, and the other tropical staples. There are some extensive tracts of open or savanna land, covered with grass, well adapted for the raising of cattle. There are also certain broad, sandy plains, not fitted for cultivation, but covered with fine pines, some of them large enough for the masts of ships; and the banks of the rivers generally are covered with forests of mahogany, rosewood, India-rubber, and other valuable trees. Altogether the coast has many natural elements of wealth; but it may be doubted if its settlement by a civilized race will be effected until the equally fertile, but more elevated, cooler, and more salubrious regions of the interior and on the Pacific coast, have become filled by an active and enterprising population. Their greater advantages will claim for them the first attention of emigrants, and to these alone can we look for the political and social regeneration of Central America, and for the ultimate rescue of the Mosquito Shore from its present condition of desolation and barbarism. (E. G. S.)

MOSSES. See BOTANY, c. iii., § 1.

MOSTAGANEM, a town of Algeria, in Lat. 36. 10. N., Long. 0. 15. E., is situated on a limestone rock, 233 feet above the sea, and about $1\frac{1}{2}$ miles from the coast. It is divided into two parts by a fertile valley, laid out in gardens and traversed by a small stream. That which stands on the left side of the stream is the town proper, the other part being inhabited exclusively by the military. The town has very much a French appearance, with wide streets and handsome squares. The principal buildings are a theatre and a large hospital. Leather, carpets, jewellery, &c., are manufactured; and an extensive trade is carried on with the interior. The harbour is not good, but it is much frequented. The neighbouring country is fertile and well-cultivated; and grain, wool, hides, and dried fruits are the principal exports. Pop. 6469.

MOSTAR, a town of Bosnia, capital of the province of Herzegovina, is situated on both sides of the Narenta, 72 miles N.W. of Cattaro. It is surrounded by embattled walls, which inclose a much larger space of ground than is actually occupied by buildings. The streets are for the most part unpaved; and the town contains several mosques and churches, and two large bazaars. The name *Mostar*, which signifies "old bridge," is derived from the Roman bridge of a single arch which crosses the river. Swords and fire-arms are manufactured here; and there is an active trade in corn, wine, fruits, cattle, tallow, and wax. Pop. 7300.

MOSTYN, a village and township of Wales, in the county of Flint, situated on the estuary of the Dee, 4 miles N.W. of Holywell. There is an elegant church here, which was built in 1845. The coal-pits in the neighbourhood are numerous, giving employment to the most of the inhabitants, and furnishing large quantities of coal for exportation. Mostyn stands on the railway between Chester and Holyhead; and communication is kept up by steamers with Liverpool. Pop. 2091.

MOSUL, a town of Asiatic Turkey, capital of a pashalic of the same name, is situated on the right bank of the Tigris, 220 miles N.W. of Baghdad. It is surrounded by walls; but these, as well as a castle which stands on an artificial island in the Tigris, and the best buildings of the town, are in a very dilapidated condition; while the whole place is very low, and fast-declining in internal prosperity and commercial importance. The streets are narrow, irregular, and crowded with beggars. The houses, which are built of

Mosses.
||
Mosul.

Mothe-le-
Vayer.
||
Motril.

stone or brick, have in general vaulted roofs surrounded by flat terraces. The streets of the town are but little raised above the level of the Tigris, and they are thus often laid under water when the river is in flood. The town contains numerous mosques (some of which are of great beauty), a college, coffee-houses, baths, khans, and bazaars. The climate is mild, but occasionally very hot in summer; and though it is in general considered a healthy place, Mosul has several times been exposed to the ravages of pestilence. There are several hot sulphur springs in the neighbourhood of the town, which are much resorted to, from their medicinal qualities. Mosul was formerly celebrated for the manufacture of muslin, which derives its name from the town; but the only manufactures now carried on are those of cotton fabrics, shawls, calicoes, &c. A considerable transit trade is carried on through Mosul between Constantinople, Syria, Baghdad, and the interior of Koordistan. Pop. estimated at 40,000.

MOTHE-LE-VAYER, FRANÇOIS DE LA, a distinguished French writer, was of noble descent, and was born at Paris in 1588. His attention was early directed by his father to the study of literature, law, and morals. Aided by a tenacious memory and by the power of assiduous application, he became distinguished for his general intelligence, and especially for his intimacy with history. The female wit, Mademoiselle de Gournay, received him into her brilliant circle, and bequeathed to him her library. Although Mothe-le-Vayer had begun to write at an early age, he did not publish any of his works until his forty-eighth year. At length his *Discours de la Contrariété d'Humours qui se trouve entre certaines Nations*, and his *Considerations sur l'Eloquence Française*, published in 1636 and 1638 respectively, brought him fully before the public. He was admitted into the French Academy in 1639. His next work, *De l'Instruction de Monsieur le Dauphin*, 4to, 1640, raised him to the height of distinction, since it led to his appointment in 1652 as tutor to the young King Louis XIV. Meanwhile he had become an avowed sceptic, and had published in 1642 a treatise entitled *De la Vertu des Païens*. On the marriage of his royal pupil in 1660, Mothe-le-Vayer retired from his public office, and gave himself up to his favourite studies. Foreign politics continued till the close of his life to be the subject of his eager attention, and one of his last questions was, "What news of the Great Mogul?" He died in 1672. Mothe-le-Vayer also wrote *Jugement sur les Anciens et Principaux Historiens Grecs et Latins*, 8vo, 1646; and *Du peu de Certitude qu'il y a dans l'Histoire*, 1668. The best edition of his collected works is that of Dresden, in 14 vols. 8vo, 1756-59.

MOTION. See ATTRACTION, DYNAMICS, MECHANICS, and STATICS.

MOTRIL, a town of Spain, in the province of Granada, situated in a rich and fertile plain, about a mile from the Mediterranean, and 38 miles S.S.E. of Granada; Lat. 36. 45. N., Long. 3. 34. W. It is irregularly built, but varies considerably in different parts; for some of the streets are narrow, dirty, and unpaved; while others are handsome, regular, and well kept. In the principal square are the town-house, a collegiate church of a clumsy appearance, and a granary. There are several other churches in the town, a nunnery, and several elementary and upper schools. The neighbouring country is rich in fruit; and large quantities of fish are got from the Mediterranean. The people are for the most part employed both in agriculture and in the fisheries. Sugar, rum, soap, earthenware, &c., are manufactured here. The town itself has no harbour, but that of Calahonda is only about 7 miles distant. The greater part of the trade of the provinces of Granada and Jaen passes through Motril. Rice, dried fish, sugar, coal, timber, leather, cotton and woollen stuffs, &c., are imported;

and oil, figs, oranges, wine, brandy, &c., are exported. Pop. 10,170.

MOTTRAM-IN-LONGDENDALE, a town of England, in the county of Chester, 9 miles E. by S. of Manchester. It is well built, and contains one Established and three Dissenting churches. There are also print-works and cotton factories in the town, in which the majority of the inhabitants are employed. Pop. (1851) 3199.

MOUFET, THOMAS, an eminent English physician and naturalist, was born in London during the first half of the sixteenth century, but at what precise date is not known. He practised medicine in the metropolis with great reputation, and towards the close of his life retired to the country. He died about the year 1600. This physician is best known by a work which was begun by Edward Wotton, and printed at London in 1634, folio, under the title of *Insectorum, seu Minimorum Insectorum Theatrum, olim ab Edwardo Wotton, Conrado Gesnero, Thomaque Pennio inchoatum, Moufeti opera sumptibusque maximis concinnatum auctum, perfectum*. A translation of it into English was published at London in 1658, folio. Martin Lister gives a very unfavourable opinion of this book. "As Moufet," says he, "made use of Wotton, Gesner, and others, an excellent work might have been expected from him; and yet his *Theatrum* is full of confusion, and he has made a very bad use of the materials with which these authors have furnished him. He is ignorant of the subject of which he treats, and his manner of expression is altogether barbarous. Besides this, he is extremely arrogant, to say no worse; for though he has copied Aldrovandus in innumerable places, he never once mentions his name." But Lay thinks that Lister, by expressing himself in this manner, has not done justice to Moufet; and he maintains that the latter has rendered an essential service to the republic of letters. He wrote *De Jure et Præstantia Chemicorum Medicamentorum, Dialogus Apologeticus*, Franc. 1584; *Nosomantica Hippocratica, sive Hippocratis Prognostica cuncta, ex omnibus ipsius scriptis, methodicè digesta*, lib. ix., Franc. 1588; *Health's Improvement, or Rules of the Nature, Method, and Manner of Preparing all sorts of Food*; enlarged by Christopher Bennet, London, 1655.

MOUKDEN, a town of the Chinese empire, capital of Manchouria, in Lat. 41. 50. N., Long. 123. 37. E., 500 miles N.E. of Pekin. It is large and populous, and is surrounded by walls. An inner wall incloses the palace, government offices, court-house, &c. The outer city, which is also walled, is inhabited chiefly by the working-classes, and has a circuit of about 10 miles.

MOULD, in the mechanical arts, is a cavity artificially cut, with a design to give its form or impression to some softer matter applied therein. Moulds are implements of great use in sculpture, foundry, and other arts. The workmen employed in melting the mineral or metallic ore dug out of mines have their several moulds to receive the melted metal as it comes out of the furnace; but these are different according to the diversity of metals and works. In gold mines they have moulds for ingots, in silver mines for bars, in copper and lead mines for pigs or salmons, in tin mines for pigs and ingots, and in iron mines for sows, chimney-backs, anvils, caldrons, pots, and other large utensils.

MOULDINGS, in *Architecture*, are projections beyond the naked wall, column, or wainscot, the assemblage of which forms cornices, door-cases, and other decorations of architecture. (See the *Glossary* to the article ARCHITECTURE.)

MOULE, a town and harbour of Guadaloupe, in the division of Grande Terre, is situated on the N.E. coast of the island, near the mouth of a small river; Lat. 16. 21. N., Long. 61. 27. W. Pop. 10,000.

MOULIN LILLE, a suburb of Lille, which derives its name from the number of wind-mills in the vicinity. Pop. 4317.

Moulins
||
Mountmellick.

MOULINS, a town of France, capital of the department of Allier, is situated on a plain on the right bank of the Allier, which is here crossed by a handsome stone bridge, 164 miles S.S.E. of Paris. The town has a cheerful appearance; and the streets, though not very wide or straight, are clean, well paved, and lined on each side with good houses, built chiefly of brick. It was formerly surrounded by fortifications, but the place of these is now occupied by public walks. The principal buildings in the town are,—the cathedral of Notre Dame, a building in the florid style of the fifteenth century, of which only the choir has been completed; the chapel of the college, which formerly belonged to the convent of the Visitation, containing the monument of the last Duke of Montmorency; the castle, formerly the residence of the Dukes of Bourbon, of which all that now remains is a square tower and some buildings erected by Catherine de Medicis, and serving as barracks; and the town-house. There are also in Moulins a court of first resort and one of commerce, a chamber of manufactures and arts, a normal school and school of design, societies of rural economy and of agriculture, a public library of 19,000 volumes, a museum of natural history, two hospitals, and a theatre. The manufactures are extensive, consisting chiefly of hardware, especially of cutlery, woollen and cotton stuffs, hosiery, glass, leather, silk, &c. There is an active trade in cutlery, corn, wine, cattle, timber, coal, charcoal, iron, &c. The history of the town can be traced as far back as the eleventh century; and in 1368 the Bourbon family took up their residence here. Moulins is also noted as the birthplace of Marshal Villars, the opponent of Marlborough at Malplaquet. Pop. (1856) 16,391.

MOULMEIN, in Hindustan, a town in the British district of Amherst, and the principal place of the Tenasserim provinces. It is situated on a small peninsula formed by three rivers, the Salwein, the Gyne, and the Attaran, and lies opposite to the town of Martaban, and about 30 miles N. of Amherst. Upon its cession to the British in 1826 by the Burmese, the site was selected for a military station; and the town, which now bears all the marks of civilization, a few years since presented a very different aspect, the accumulation of huts of which it then consisted having been converted into a fine seaport-town, with open streets, quays, markets, churches, and schools. The main street runs parallel to the river, and communicates with different parts of the town by means of smaller streets joining it at right angles. The population of the town is given at 17,042. Vast forests in the vicinity yield an inexhaustible supply of teak timber, which, coupled with other local advantages, has enabled Moulmein to supplant Chittagong and other ports on the eastern coast of the Bay of Bengal in ship-building. The East India Company's steamer Tenasserim and Her Majesty's sloop Malacca were built at this port. One of the Indian newspapers, styled the *Moulmein Guardian*, is printed in this town. N. Lat. 16. 30., E. Long. 97. 42.

MOUNTAINS. See PHYSICAL GEOGRAPHY.

MOUNT EVEREST, a mountain of the Himalaya range, situated between the peak of Kinchunga in Sikkim and the city of Khatmandu in Nepaul, and presumed to be the loftest summit in the world. Its elevation is 29,002 feet above the level of the sea, surpassing that of the highest peak of the Andes by above half a mile of perpendicular altitude. This mountain, which has been recently discovered, has been named Mount Everest, in compliment to the late surveyor-general of India.

MOUNTMELLICK, a market-town of Ireland, in Queen's County, situated on a bend of the River Owenas, 45 miles W.S.W. of Dublin. The houses are well built; and the town contains a parish church, and four other churches, belonging to Roman Catholics, Methodists, and Quakers; a court-house, a bank, several schools, a dispen-

sary, and a poor's-house. The manufacturing industry of the place is active; and there are flour-mills, an iron and brass foundry, breweries, soap-works, tanneries, and potteries. The trade is considerable; and eight yearly fairs are held here. The population consists to a large extent of Quakers, and amounts to 3657.

MOUNTRATH, a market-town in Queen's County, Ireland, is situated on a tributary of the Nore, 53 miles W.S.W. of Dublin. The principal buildings are,—a parish church, Roman Catholic and Methodist churches, a court-house, a market-house, and a jail. There are also a monastery, a nunnery, several schools for the higher and lower classes, and a dispensary. The chief manufacturing establishments are cotton and worsted factories, an oil-mill, and a large brewery. Several annual fairs are held here. Pop. 2100.

MOUNT'S BAY, a large bay on the S.W. coast of Cornwall, lying between two promontories,—Lizard Point on the E., and Land's End on the W. It is 18 miles wide, and runs 8 miles into the land; while its depth varies from 3 to 30 fathoms. The name is derived from St Michael's Mount, which is situated on its shore.

MOUNTSOREL, a market-town of England, in the county of Leicester, on a steep hill near the Soar, from which it derives its name, 7 miles N. of Leicester. It contains two Established churches, Methodist and Baptist chapels, and several schools. The inhabitants are employed in the manufacture of hosiery, and in the quarries in the vicinity, where a very hard trap rock is obtained, of which the town is built. Pop. 1536.

MOURNING, a particular dress or habit worn to signify grief upon some melancholy occasion, particularly the death of friends or of great public characters. The modes of mourning are various in different countries, as are also the colours used for that purpose. In Europe the ordinary colour for mourning is black, in China it is white, in Turkey blue or violet, in Egypt yellow, in Ethiopia, brown. White formerly obtained in Castile on the death of their princes; and Herrera observes, that the last time it was used was in 1498, on the death of Prince John. The Kings of France mourn in violet. Each people pretend to have their reasons for the particular colour of their mourning: white is supposed to denote purity; yellow indicates that death is the end of human hopes, because leaves when they fall, and flowers when they fade, become yellow; brown denotes the earth, whither the dead return; black signifies the privation of life, as being the privation of light; blue expresses the happiness which it is hoped the deceased enjoys; and purple or violet betokens sorrow on the one side and hope on the other, as being a mixture of black and blue.

Mourning amongst the ancients was expressed in a great variety of ways. Amongst the Jews, on the death of their relations or intimate friends, grief or mourning was signified by weeping, tearing their clothes, smiting their breasts or tearing them with their nails, pulling or cutting off their hair and beards, walking barefooted, lying upon the ground, fasting, &c. They kept themselves closely shut up in their houses, covered their faces, and abstained from all work, even reading the law and saying their usual prayers. They neither dressed, nor made their beds, nor cleaned their persons, nor saluted anybody; so that sulkiness appears to have been an indication of sorrow, and dirtiness of distress. The time of mourning amongst the Jews was generally seven days, though this was lengthened or shortened according to circumstances; but thirty days were thought sufficient upon the severest occasions. The different periods of the time of mourning required different degrees of grief, and different tokens of it.

The Greeks, upon the death of friends, showed their sorrow by secluding themselves from all gaiety, especially

Mountrath
||
Mourning.

Mourzük
||
Mout.

entertainments, games, public solemnities, the enjoyment of wine, and the delights of music. They sat in gloomy and solitary places, stripped themselves of all external ornaments, put on a coarse black stuff by way of mourning, tore their hair, shaved their heads, rolled themselves in the dust and mire, sprinkled ashes upon their heads, smote their breasts with their palms, tore their faces, and frequently cried out with a lamentable voice and drawling tone, reiterating the interjection $\epsilon, \epsilon, \epsilon, \epsilon$. Hence funeral lamentations were called *Ελεγχοί*. If they appeared in public during the time of mourning, they had a veil thrown over their faces and heads. During the funeral procession, certain persons, called *ἐξάρχοντες θρήνων*, marched before, and sung melancholy strains. These vocal mourners sung thrice during the procession round the pile and round the grave. Flutes were also used to heighten the solemnity. At the funerals of soldiers, their fellow-soldiers who attended, as a testimony of their affliction, held their shields, their spears, and the rest of their armour inverted.

The tokens of private grief amongst the Romans were nearly the same as those amongst the Greeks. Black or dark brown were the colours of the mourning habits worn by the men, and they were also common to the women. The mourning of the emperors at first was black. In the time of Augustus the women wore white veils, but the rest of their dress was black. From the time of Domitian they wore nothing but white habits, without any ornaments of gold, jewels, or pearls. The men let their hair and beards grow, and wore no wreaths of flowers on their heads whilst the days of mourning continued. The longest time of mourning was ten months. This was Numa's establishment, and included his whole year. During this time it was infamous for a widow to marry. Mourning was not used for children who died under three years of age. From this age to ten they mourned as many months as the child was years old. A remarkable victory, or other happy event, occasioned the shortening of the time of mourning. The birth of a child, or the attainment of any remarkable honour in the family, certain feasts in honour of the gods, or the consecration of a temple, had the same effect. After the battle of Cannæ the commonwealth decreed that mourning should not be worn for more than thirty days, that the loss sustained might be forgotten as soon as possible. When public magistrates or persons of great note died, also when any remarkable calamity happened, all public meetings were intermitted; the schools of exercise, baths, shops, temples, and all places of concourse, were shut up; and the whole city put on an appearance of sorrow; the senators laid aside the *laticlave*, and the consuls sat in a lower seat than ordinary. This was also the custom of Athens, and was observed upon the death of Socrates, not long after he had been sentenced to death by their judges. *Πραξις*, or mourning women, went about the streets. This was also customary amongst the Jews as well as the Greeks and Romans. (Jerem. ix. 17.)

MOURZUK. See **FEZZAN**.

MOU, or **MOOT**, a town of Asiatic Turkey, in the pashalic of Itshili, is situated 88 miles S.E. of Konia. The principal building is a castle, surrounded by embattled walls, with several square towers, and a round one in the centre. There are some mosques and baths, but these are mostly in a ruinous condition. The inhabitants live for the most part in huts of clay and reeds. The streets and the sites of the principal buildings of an ancient city (supposed by Beaufort to have been Philadelphia, but by Leake to have been Claudiopolis), may be distinctly traced among the more modern edifices; and many marble columns and other ornaments, lying neglected and half buried in the earth, or built into Turkish mosques, now also in ruins, attest the former magnificence of the Grecian city.

MOUTON, **JEAN**, an eminent French musician, born in 1461, of whose life very little is known. Glarean, who was personally acquainted with Mouton at Paris in 1521, declares him to have been a native of France. Some writers have stated that Mouton was chapel-master to Louis XII. and Francis I. of France, but there is no evidence for that. He was a pupil of Josquin Deprès, according to Adrian Willaert, his scholar. Several of his motets were published at Venice and at Paris in the earlier part of the sixteenth century. Hawkins and Burney gave specimens of his music; and Forkel, in the second volume of his *History of Music*, pp. 660-7, published Mouton's motet for four voices, *Confitemini Domino*. In the article **MUSIC** will be found an elegant air by Mouton, and a very remarkable passage of unprepared dissonances from one of his motets. (G. F. G.)

MOVEMENT, in music, usually relates to the degree of slowness or quickness with which a piece of music is to be performed. The different degrees of movement are divided into five principal kinds, designated by the following terms in their order:—1st, *Largo* or *Lento*; 2d, *Adagio*; 3d, *Andante*; 4th, *Allegro*; 5th, *Presto*. All other movements, such as *Grave*, *Larghetto*, *Andantino*, *Tempo giusto*, *Tempo di Minuetto*, *Allegretto*, and *Prestissimo*, are mere modifications of the preceding five kinds. It is found necessary, however, to employ other auxiliary terms to indicate not only the degree of movement, but also the style and manner of performance required. These auxiliary terms are,—*affettuoso*, *agitato*, *amoroso*, *grazioso*, *maestoso*, *sostenuto*, *giusto*, *moderato*, *cantabile*, *con brio*, *vivace*, *spiritoso assai*, *con energia*, *appassionato*, &c., &c. But all these terms are vague; and the right movement, as well as the best expression, suitable to this or that piece of music, must be left to the skill and feeling of the accomplished performer who has studied musical composition and the styles of the various schools of music, ancient and modern. The composer may fix precisely the time-movement of his piece of music by means of the metronome; but he has no means of showing exactly, by any written signs, what style and expression he wishes the performer to employ. (See **METRONOME**.) (G. F. G.)

MOWEE, or **MAUI**, an island of the Sandwich group, situated in Lat. 20. 44. N., Long. 155. 58. W., 24 miles N.W. of Hawaii. It stretches from N.W. to S.E. for about 40 miles, and consists of two elevated portions of an oval shape, joined together by a low sandy isthmus, 9 miles wide. The south-eastern portion rises almost perpendicularly to a height of more than 10,000 feet in Mount Haleakala; while the north-western elevation is much inferior in height. The structure of the island, like that of the others in the same group, is volcanic, and exhibits a striking contrast between the barrenness of the mountains and the luxuriant vegetation of the valleys and lower regions. Mowee is considered the richest in soil and the most productive of the Sandwich Islands; but the cultivated ground does not exceed one-tenth of the whole area. The town of Lahaina, which is situated on a bay of the same name on the S.W. coast, contains a church, schools, a market-house, and a reading-room. Missionaries from the United States first settled here in 1832, and have since acquired great influence over the natives. The church consists of about 300 members. The population of the town is probably about 3000. The harbour of Lahaina is formed by two projecting rocks, and is much resorted to by whaling vessels for supplies of provisions. Pop. estimated at more than 20,000.

MOZAMBIQUE, a name applied to a large extent of the seaboard of Eastern Africa, belonging to Portugal; as well as to the chief town of the same. The former is bounded E. by the Mozambique Channel, N. by Cape Delgado (S. Lat. 10. 38.), and S. by Delagoa

Monton
||
Mozambique.

Mozam-
bique.

Bay (S. Lat. 26.), and has an extent of about 1200 miles. The entire territory, with the exception of some settlements on the River Zambesi, is confined to the coast, and cannot be said to have any definite interior boundary. It was discovered in 1498 by Vasco de Gama, the great Portuguese navigator, and the chief town was founded by Affonso de Albuquerque in 1506. The coast is characterized by the two prominent headlands of Cape Corrientes in the S., and Cape Delgado in the N.; and also by several large bays, the chief of which are Delagoa, Mocambo, and Pamba. Between Delagoa Bay and Cape Corrientes, and from Mozambique city to Cape Delgado, the shores are described as high and precipitous; while reefs and numerous islands lie off the land nearly throughout its entire length. Many large streams discharge themselves here. Of these the principal are,—the Maniza and Inhampura, between Delagoa Bay and Inhambana town; the Inhambana and Great Sofala, between the towns of the same name; and the Buzé, N. of Sofala, which is navigable up to Mossiquire. The Zambesi, the largest river of Eastern Africa, discharges itself by several mouths at the middle point of the Mozambique coast. The principal branches of the delta are the Luabo and Kilimane, the former, and southernmost, having the largest volume of water. (For further information on this river, see the article ZAMBESI.) The St George enters the sea between Kilimane mouth and Mozambique city; while the Fernando Veloso, and Mangaló enter Tungué Bay further to the north. Settlements have been established along the coast at the most accessible points, and where easy communication may be had with the interior. The Portuguese, however, have so neglected their possessions, that in every instance the trade and government are now in a very feeble condition. Indeed, at some stations the government may be said to rest more with the influential chiefs of the neighbouring tribes than with the Portuguese governor or representative, who frequently holds his position as much from the clemency or indolence of the natives as from any fear they have of his power. The military force is very small for such an extent of territory, and is composed of the worst class of soldiers, who are either convicts from Europe, or cowardly disaffected half-castes or natives. The coast, for administrative purposes, is divided into six sub-districts, and Mozambique is the head district. The former are (going from N. to S.) Cape Delgado, Kilimane (with military stations at Senna and Tete in the interior), Sofala, Inhambana, and Lorenzo Marques. A governor-general and secretary, appointed by the crown, administer the government, assisted by a *junta*, which is composed of a president, treasurer, and twelve members. The judicial staff includes a high judge and substitute, as well as an attorney and delegate. The established religion is Roman Catholic, and is superintended by a prelate, a prior, and twelve parochial priests. Education, which, like religion, is here at a very low ebb, is dispensed by sixteen teachers in all, four of whom are females. Most of these, moreover, reside in the capital. The military staff consists of two commanders; and the regular force amounts to 1096 men,—distributed into the Mozambique foot battalion, 368 men; the district company of Cape Delgado, 161 men; and the district companies of Kilimane, Senna, Tete, Zumbo, Inhambana, Sofala, and Lorenzo, 81 men each. Most of these stations are commanded by a major and adjutant. A militia force, composed of natives, is nominally extant; but, with the exception of its officers, who are native chiefs, receiving from their appointments from L.4 to L.20 a year, its very numbers are not ascertained. The cost of the military establishment amounts annually to about L.9522, and that of the marine, which consists of a brig and a smaller vessel, to L.2552. The territory contains an estimated population of 300,000 souls, including 22,000 slaves; but of that num-

ber there were only 3600 regular Portuguese subjects in 1848, and 3250 in 1852.

Little is known of the condition or resources of the country, except at the few stations placed along the coast; and these we shall now notice shortly in their order from N. to S., thereby giving a general idea of those parts not yet within European influence.

San João, on the island of Ibo, lying close upon the mainland, is the northernmost of these settlements, and is situated between S. Lat. 12. 20. and E. Long. 40. 30. It is defended by three forts, and belongs to Cape Delgado district; which abounds in cotton, coffee, tobacco, gum, and amber, but has comparatively little trade. Pop. 140 Christians, 800 free blacks, and 600 slaves.

Mozambique city, on an island of the same name, in S. Lat. 15. 1., E. Lon. 40. 5., and a short distance from the continent, was founded in 1763, and incorporated as chief town in 1813. The cognominal district to which it pertains extends on the mainland from Pamba Bay, in S. Lat. 12. 58., to the Moma River, in S. Lat. 16. 45., a length of about 300 miles; but its interior frontier is undefined. Many of the African tribes here, who do not formally acknowledge the sovereignty of Portugal, yet pay tribute annually. The site of Mozambique city was chosen for its security, and supposed advantageous position for controlling the coast; but otherwise a worse place could not have been selected on the whole shore. It is barren, confined, and very ill watered. Three forts command the island, and could supply ample accommodation for a large garrison. The town, which is notorious for its filthiness, has nevertheless some good private houses as well as public buildings. Among the latter there are a marine arsenal, an hospital, and a *casa da misericordia*; while a military hospital and public baths are situated in the south part of the island. The trade of the place is at its height in the autumn, when the blacks from the interior or adjacent ports bring their goods hither for barter. Direct communication, however, with the interior is much obstructed by want of a fort on the mainland opposite. The slave trade thrives here, connived at by the authorities, who are said to make great gains from the prices required from the traders by way of bribes or licenses; and large numbers are still kept on the island for the purposes of trade, in spite of art. 145, § 8, of the constitution. These poor creatures, who number 20,000, are said to be ill clothed, ill fed, and shockingly ill treated. It is, moreover, a matter worthy of remark, that the blacks who have received their freedom here are a peaceful and industrious class, true to the government, and ever ready to receive religious instruction. Pop. of city, 270 Christians, 102 Banyans or Portuguese Hindoos from Goa, 1150 blacks, and 7000 slaves; total 8522.

Farther down the coast, between the last-mentioned town and Kilimane, is Quizango or Angozha, an old settlement of the Portuguese, but which, being attacked and destroyed in 1847 by a rebel chief of European origin, was abandoned. Kilimane, or Quillimane, a small town 12 miles above the mouth of the Kilimane, a delta branch of the Zambesi, is situated S. Lat. 17. 53., and E. Lon. 36. 56., in a cognominal district, comprising the Zambesi delta, with the two stations of Senna and Tete. It stands on a mud bank on the left side of the stream, surrounded by swamps, which render the ground on which the town is situated so soft that the walls of the houses are always sinking. The climate is very unhealthy, and fevers are extremely prevalent. A large trade in slaves is carried on here surreptitiously. They are collected in the town from the interior, and remain there till the ships from Rio de Janeiro and other ports of America arrive in the river. Pop. of town, 200 Christians, 32 free blacks, and 3260 slaves.

Mozam-
bique.

Mozambique.

Senna, a decayed town of the interior, on the right bank of the Zambesi, about 200 miles above Kilimane, contains about 30 houses, and is surrounded by conical hills, on one of which there is a dismantled fort. Though once a thriving station, it has now, from repeated attacks by the neighbouring tribes, and from an insufficient garrison, become of little consequence as a place of trade. The vicinity, however, has all the resources to render it an important town, possessing as it does rich iron and copper deposits, as well as producing oil, fruits, and cereals in abundance. Pop. of town, about 108 Christians and 2850 slaves.

Tete, about 300 miles farther up the Zambesi, on the right bank of the same, is a walled town containing nearly 1200 huts, and defended by the fort Santiago Maior. It is well situated for trade, and was, before the formal abolition of the slave trade, the most important commercial port on the Zambesi. Recently, however, the town has much declined, although not to the same extent as Senna. It has frequently, like it, suffered from attacks made by the neighbouring tribes and rebel half-castes. Excellent iron, coal, copper, and marble, abound in the vicinity, but are left unworked. Gold also exists, but is not collected to so great an extent as formerly. Dr Livingstone, who visited this place in March 1856, says that 130 lb. of gold were annually obtained here before a stoppage was put to the slave trade, but now the amount has diminished to from 8 to 10 lb. annually. Pop. of town estimated by Livingstone at 2500.

The next station belonging to Portugal is Sofala, situated on the sea-coast, about 250 miles S.E. of Kilimane, S. Lat. 20. 12., and E. Lon. 35. 20., formerly the chief town of a large district of the same name, but now much fallen in importance. Its harbour, however, is one of the best on the shore, and the neighbourhood abounds in gold, ivory, and precious stones.

Inhambana, situated on a peninsula at the mouth of a cognominal river, more than 200 miles south of Sofala, in S. Lat. 23. 51., and E. Lon. 35. 30., has a considerable trade in slaves and ivory. The river here has little fall of water, and its entrance is dangerous; while the country round the town is flat, subject to inundation, and very unhealthy. A hill a little beyond, however, is much resorted to by the inhabitants for its comparative salubrity. Regular government is all but extinct here. Pop. 182 Christians, 205 free blacks, and 1852 slaves.

The last station on the Mozambique coast is that of Lorenzo Marques, situated in Delagoa Bay, S. Lat. 26., and E. Lon. 30. 30., and surrounded by a swampy district of land, subject to periodical inundation, and very unhealthy. The bay, however, forms a secure and convenient harbour for vessels rounding the Cape; while the vicinity is famous for its fertility in all the articles of South African produce. Excellent Indian corn, rice, cassia, and coffee grow here with little culture, and building timber of the best quality is abundant. The trade is mostly contraband, on account of the impotency of the government, and consists in the export of ivory, hides, and amber, in return for cheap calicoes and beads from America and the Cape Colony. Numerous mutinies have occurred here, ending with the murder of the governor,—an atrocity which has brought the place into disrepute, and hastened its fall. Pop. about 50 Christians and 256 slaves.

From what has been said of the condition of the various settlements on this shore, it must be evident that a new system of administration is urgently required. The resources of the country are great and various; and were the government steady and liberal in its policy, their development would be easily accomplished, and attended with great profit both to the home government and to the tribes of Africa. A company, called the East Africa Company, was formed lately in Portugal avowedly for this purpose, and

laid certain conditions before the King, on which they bound themselves to re-open the country to European enterprise, but these were not accepted by the government.

MOZAMBIQUE CHANNEL, a wide strait of the Indian Ocean, separating the island of Madagascar from the continent of Africa, between S. Lat. 12. and 25., and E. Lon. 35. and 45. It has a length of about 1000 miles, and a breadth of from 300 miles at Mozambique city to about 600 miles at the widest part. The Comoros, a numerous cluster of islands, are situated at its northern outlet.

MOZART, JOHANN-CHRYSOSTOM-WOLFGANG-GOTTLIEB, the illustrious musical composer, was born at Salzburg on the 27th of January 1756. He was the son of Leopold Mozart, a musician in the employment of the Prince-Archbishop of Salzburg, and Anna Maria Pertl. Both parents were noted for their uncommon beauty. Mozart was scarcely three years old when he manifested the most astonishing disposition for music. With an instinctive perception of beauty, his great delight was to seek for *thirds* on the piano, and nothing could equal his joy when he found this harmonious chord. At the age of four his father taught him some minuets and other pieces of music. Mozart would learn a minuet in half an hour, and a longer piece in less than twice that time; and immediately afterwards he played them with remarkable clearness, and perfectly in time. Before he was six he had invented several small pieces himself, and even attempted compositions of some extent and intricacy. The vivacity of his mind led him to attach himself easily to every new object that was presented to him. He pursued the usual tasks of childhood with ardour; and when learning arithmetic, covered the tables, chairs, and walls with figures which he had chalked upon them. Music, however, soon became his favourite study, and in his juvenile efforts in composition he showed a consistency of thought and a symmetry of design which promised a maturity of the highest genius.

One day his father, returning from church with a friend, found his son busy writing. "What are you doing there, my little fellow?" he asked. "I am composing a concerto for the harpsichord, and have almost got to the end of the first part." "Let us see this fine scrawl." "No, I have not yet finished it." The father, however, took the paper, and showed his friend a sheet full of notes, which could scarcely be deciphered for the blots of ink. The two friends at first laughed at this heap of scribbling; but after regarding it a little more seriously, the father's eyes overflowed with tears of joy and wonder. "Look, my friend," said he, with a smile of delight, "everything is composed according to rule. It is a pity the piece cannot be made any use of; but it is too difficult; nobody would be able to play it." "It is a concerto," replied the son, "and must be studied till it can be properly played. This is the style in which it ought to be executed." He accordingly began to play, but succeeded only so far as to give them an idea of what he intended.

The extraordinary precocity of his son's genius induced Leopold Mozart to exhibit him at the different courts in Germany. As soon, therefore, as Wolfgang had attained his sixth year, the Mozart family, consisting of the father, mother, and a young daughter who had made very considerable proficiency on the harpsichord, and Wolfgang, took a journey to Munich. This expedition succeeded in every respect. The young artists, delighted at the reception which they had met with, redoubled their application, and acquired a degree of execution on the piano which no longer required the consideration of their youth to render it remarkable. During the autumn of the year 1762 the whole family repaired to Vienna, where the children performed before the court. Here they met with the celebrated Wagenseil. When Mozart, who knew already how to esteem the approbation of a great master, sat down to play before

Mozambique Channel || Mozart.

Mozart. the Emperor Francis, he asked his Majesty, "Is not M. Wagenseil here? we must send for him; he understands these things." The Emperor sent for Wagenseil, and gave up his place to him at the side of the piano. "Sir," said Mozart to the composer, "I am going to play one of your concertos; you must turn over the leaves for me."

Hitherto the young Mozart had only played upon the harpsichord. On his return from Vienna to Salzburg, he brought with him a small violin, and amused himself with it. Wenzl, a skilful violin-player, came to consult Leopold Mozart about some trios he had written. It was proposed to try the music. The father played the bass, Wenzl the first violin, and Schachtner, the archbishop's trumpeter, was to have played the second; but Wolfgang insisted so much on being allowed to take this part, that his father at last consented to his playing it on his little violin. It was the first time he had heard his son seriously attempt this instrument, which, to the astonishment and delight of the party, he played with marvellous precision.

Every day afforded fresh proofs of Mozart's exquisite organization for music. He could distinguish and point out the slightest differences of sound; and every false or even rough note, not softened by some chord, was a torture to him. It was from this cause that during the early part of his childhood, and even till he had attained his tenth year, he had an insurmountable horror for the trumpet when it was not used merely as an accompaniment. The sight of this instrument produced upon him much the same impression as that of a loaded pistol does upon other children when pointed at them in sport. His father thought he could cure him of this fear by causing the trumpet to be blown in his presence, notwithstanding his son's entreaties to be spared that torment; but at the first blast the boy turned pale, fell upon the floor, and would probably have been in convulsions if they had not immediately ceased.

In 1763, when Mozart was in his seventh year, his family set out upon their first expedition beyond the boundaries of Germany; and it is from this period that the celebrity of the name of Mozart in Europe is to be dated. They visited Paris and many other cities on the Continent; and in the year 1764 came to London, where the children played before the King. Mozart also played the organ at the Chapel Royal; and with this the King was even more pleased than with his performance on the harpsichord. During this visit he composed six sonatas, which he dedicated to the Queen. He afterwards returned to France, whence he proceeded to Holland and Switzerland; and on his arrival at his native place in 1768, he composed, at the request of the Emperor Joseph, the music of an operabuffa called the *Finta Semplice*, which was approved of by Hasse and Metastasio. At the dedication of the church of the Orphans he composed the music of the mass, and directed this solemn service, in the presence of the imperial court, although he was at that period only twelve years old.

In the month of December 1769 his father took him to Italy, and in every city met with an enthusiastic reception. Young Mozart had not as yet ventured out of the beaten track of composers; but preserving the old forms of melody and harmony, he wrote in a style which was particularly learned and correct. His operas at this period were thought to have an air of stiffness, from the contrapuntal knowledge which they exhibited. What principally distinguished him from other composers, was the facility with which he scored, and the extraordinary fluency of his ideas. It was probably, too, from reading Metastasio at this period that Mozart's taste in lyric poetry was formed; for in maturer life he was fastidious in the choice of the words he set to music, and the uninterrupted flow of melody and versification distinguished his airs from

those of any other composer. Another circumstance of the Italian tour which proved influential upon the after life of Mozart, was the daily hearing of the highest and most pathetic style of church music, Italy having in the latter part of the last century produced some of her greatest ecclesiastical works. In the celebrated *Requiem*, which was composed purely from love of the *expressive* in sacred music, we may discover the result of the author's young devotion to this branch of the art, the consequence of listening to choral effects in the cathedrals of Italy.

Mozart having engaged to produce the first opera for the carnival of Milan, our travellers proceeded to Bologna, where Wolfgang found an enthusiastic admirer in Padre Martini, who was astonished to find a boy of fourteen years old capable of giving answers instantly in the *rigore modi* to any subject of fugue laid before him. In Rome Mozart gave a miraculous attestation of his quickness of ear and extensive memory by bringing away from the Sistine chapel the *Miserere* of Allegri, a work full of imitation and repercussion, mostly for a double choir, and continually changing in the combination and relation of the parts. He drew out a sketch of this celebrated composition upon the first hearing, and filled it up from recollection at home. He then repaired to the second and last performance with his manuscript in his hat, and corrected it. He afterwards produced his copy at a concert in Rome, and one of the singers who sang at the performance of the *Miserere* pronounced it perfect. Mozart thus became famous in Rome, a city where it was most difficult to excite attention in anything relating to the fine arts, on account of the numerous productions of art which were then every day presented, and formed subjects of constant and familiar contemplation.

On December 26, 1771, the first representation of his opera *Mitridate Re di Ponto* took place at Milan. It met with remarkable favour, and was performed twenty-two nights in succession. He afterwards wrote several other operas, one of which, entitled *Lucio Silla*, was likewise represented twenty times. But the epoch at which Mozart's genius ripened may be dated from his twentieth year. Constant study and practice had given him ease in composition, and ideas came thicker with his early manhood. The fire, the melodiousness, the boldness of harmony, the inexhaustible invention, which characterize his works, were at this time apparent. He began to think in a manner entirely independent, and to perform what he had promised as a regenerator of the musical art.

Mozart produced his first great opera, *Idomeneo*, in his twenty-fifth year. He was then enamoured of Mademoiselle Constance Weber, a celebrated actress, whom he afterwards married. The family of his mistress having opposed the match on account of his unsettled habits and situation, he was desirous of showing them that, although he had no recognised rank in society, he nevertheless possessed the means of obtaining consideration; and his attachment to Constance supplied him with the subject of the impassioned airs which his work required. The love and vanity of the young composer, thus stimulated to the highest pitch, enabled him to produce the opera of *Idomeneo*, which he always regarded as one of his best, and from which he has frequently borrowed ideas for his subsequent works.

Mozart being now happily married and settled, gave himself up to his profession. In 1786 he produced *Le Nozze di Figaro*; in 1787, *Il Don Giovanni*; and in 1788, *Così fan Tutte*; and in 1791, his operas *La Clemenza di Tito* and *Die Zauberflöte*, also his *Requiem*, which remained unfinished. He wrote only three German operas, *Die Zauberflöte*, *Die Entführung aus dem Serail*, and *Der Schauspieler-director*.

His works composed for the stage consist altogether of

Mozart.

Mozart. fourteen operas. He left seventeen symphonies and instrumental pieces of all kinds, besides masses and other church compositions. He was one of the first piano-forte performers in Europe. He played with extraordinary rapidity, and the execution of his left hand was especially admired. Haydn said, "I never can forget Mozart's playing; it went to the heart."

Entirely absorbed in music, this great man was a child in almost every other respect. His hands were so wedded to the piano, that he could use them for nothing else. At table his wife carved for him; and in everything relating to money or to the management of his domestic affairs, or even the choice and arrangement of his amusements, he was entirely under her guidance. But seated at the piano-forte, he appeared a being of another order. His mind then took wing, and his whole attention was directed to the development of his art. His health was very delicate, and during the latter part of his too short life it declined rapidly. At times he laboured under a profound melancholy, and in this state he wrote *Die Zauberflöte*, the *Clemenza di Tito*, and his celebrated mass in D minor, commonly known by the name of his *Requiem*. The circumstances which attended the composition of the last of these works are too remarkable to be omitted in any notice of the life of Mozart.

One day, when his spirits were unusually oppressed, a stranger of a tall, dignified appearance was introduced. The manners of this stranger were grave and impressive, and he told Mozart that he came from a person who did not wish to be known, to request he would compose a solemn mass, as a requiem for the soul of a friend whom he had recently lost, and whose memory he was desirous of commemorating by this solemn service. Mozart undertook the task, and engaged to have it completed in a month. The stranger begged to know what price he set upon his work, and having immediately paid him a hundred ducats, took his leave. The mystery of this visit seemed to have a very strong effect upon the mind of the musician. He brooded over it for some time, and then suddenly calling for writing materials, began to compose with extraordinary ardour. This application, however, was more than his strength could support; it brought on fainting fits, and his increasing illness obliged him to suspend his work. "I am writing this requiem for myself," said he abruptly to his wife one day; "it will serve for my own funeral service;" and this impression never afterwards left him. At the expiration of the month, the mysterious stranger appeared, and demanded the requiem. "I have found it impossible," said Mozart, "to keep my word; the work has interested me more than I expected, and I have extended it beyond my first design. I shall require another month to finish it." The stranger made no objection; but observing, that for this additional trouble it was but just to increase the premium, laid down fifty ducats more, and promised to return at the time appointed. Astonished at the whole proceedings, Mozart ordered a servant to follow this singular personage, and if possible find out who he was; the man, however, lost sight of him, and was obliged to return as he went. Mozart, now more than ever persuaded that he was a messenger from the other world sent to warn him that his end was approaching, applied with fresh zeal to the requiem, and in spite of the exhausted state both of his mind and body, completed it before the end of the month. At the appointed day the stranger returned, but Mozart was no more. He died on the 5th December 1791, before he had completed his thirty-sixth year.

The distinguishing characteristic of the music of Mozart is its power of touching the deepest feelings of the soul. He has been justly styled the Raffaello of music. He had many of the fine qualities and modest perfections

of the great painter, whom also he resembled in the fertility and variety of his genius. Mozart embraced his art in its whole extent, and excelled in all its departments. When, indeed, we bring into view all his qualifications as a composer and a practical musician, the result is astonishing. The same man, under the age of thirty-six, was at the head of dramatic, sinfonia, and piano-forte music; he was eminent in the sacred style, and equally at his ease in every variety, from the elaborate concerto to the simplest pieces of music. He put forth about 800 compositions, including masses, motets, operas, and fragments of different kinds; at the same time supporting himself by teaching and giving public performances, at which he executed concertos on the piano-forte, the violin, the organ, or played extempore.

Of his operas, he esteemed most highly *Il don Giovanni* and *Idomeneo*. He seldom spoke of his own works; but of the *Don Giovanni* he one day observed, "This opera was not composed for the public of Vienna; it is better suited to Prague: but, to say the truth, I wrote it only for myself and my friends." In this extraordinary production, so remarkable for exquisite melodies and profound harmonies, the playful, the tender, the pathetic, the mysterious, the sublime, and the terrible may be distinctly traced. The composer exhibits throughout the work the most romantic imagination; and in the awful accompaniment to the reply of the statue we have a specimen of composition replete with terrific expression, but at the same time perfectly free from inflation or bombast. The ghost scene in the last act may be considered as the greatest effort of dramatic composition. Well has the style of Mozart been described as that of Shakspeare in music. The fear of Leporello is painted with true comic spirit; a thing rather unusual with Mozart. But melancholy is the prevailing passion in this masterpiece; and so strong, so distinct, so real is the imagery in which it is presented to the soul, that minds possessed of the least enthusiasm are sure to be moved.

We have already seen that the *Idomeneo* was the first work produced by Mozart that raised his name to celebrity as a dramatic composer. This opera, and the *Clemenza di Tito*, are, in the opinion of judges, considered as the two best serious operas extant. His opera of *Le Nozze di Figaro* is also much admired. In this piece it must be admitted that Mozart has changed the picture of Beaumarchais. The spirit of the original is preserved only in the situations; all the characters are altered to the tender and impassioned. But although the brilliant wit of the French author has not been conveyed, yet, as a work of pure tenderness and melancholy, entirely divested of any unsuitable admixture of the majestic and the tragical, the *Nozze di Figaro* is unrivalled. It is difficult to form any idea of the *Zauberflöte* without having seen it. The story, which is like the wandering of a delirious imagination, harmonizes admirably with the genius of the musician. The subject of *Così fan Tutte* is unsuitable to Mozart, who could not trifle with love. The tender parts of the characters in this opera are the best.

The sacred compositions of Mozart are celebrated all over Europe, and frequently performed in the Roman Catholic churches. Of these works, the most sublime is the *Requiem*; but several of his other masses and motets are noted for their grandeur and beauty. His symphonies, quartets, and other works for the orchestra and stringed instruments, rank in estimation with those of Haydn and Beethoven. His piano-forte writings are also justly esteemed. Mozart's sympathy was most extensive; he participated with Sebastian Bach in the beauty of the fugue, with Handel in the grandeur of church music, with Gluck in the serious opera, with Haydn in instrumental music, and in the universality of his genius surpassed them all.

Mozdok

||
Mstislavl.

In the exterior of Mozart there was nothing remarkable; he was diminutive in person, and had a very agreeable countenance, which, however, did not at the first glance discover the greatness of his genius. His eyes were tolerably large and well shaped, more heavy than fiery in the expression; and when he was thin they were rather prominent. His sight was quick and strong; but he had an unsteady, abstracted look, except when seated at the piano-forte, and then the whole form of his visage changed. His hands were small and beautiful, and he used them so softly and naturally upon the piano-forte, that the eye was no less delighted than the ear. His head was rather large in proportion to his body, but his hands and feet were in perfect symmetry. The stunted growth of Mozart's body may have arisen from the efforts of his mind. He was always good-humoured, but very absent, and in answering questions seemed to be thinking of something else. Mozart had six children, but two sons only survived him. His widow married M. von Nissen at Vienna, who published in 1828 a full and excellent biographical account of the composer.

(See the Baron de Grimm's *Correspondance Littéraire* for some interesting notices of Mozart in his boyhood; the Honourable Daines Barrington's notice of Mozart in the *Philosophical Transactions*, 1770; A. H. F. von Schlichtegroll's biographical notice of Mozart in vol. i., for 1791, of *Necrologie der Deutschen*, Gotha, Perthes; and also the same author's *Musikalische Correspondenz* for 1792; a Life of Mozart, and æsthetic examination of his works (in German), Erfurt, 1803; Ginguené, "Notices sur Mozart," in vol. xxxi. of *Décade Philosophique*; Schizzi, *Elogio Storico* on Mozart, Cremona, 1817; G. N. von Nissen, *Biographie* of Mozart, Leipsic, 1828, 8vo, pp. 702, and Supplement, in the same year, pp. 219 (this contains portrait and list of musical compositions); Herr Otto Jahm's *Life of Mozart* (in German), with two engraved portraits and a lithographed fac-simile of his handwriting on a folio sheet, large 8vo, xl. and 716 pages, Leipsic, Breitkopf and Härtel, 1856). (A. H.)

MOZDOK, a town of European Russia, in the government of Caucasus, is situated on the Terek, near the pass of the Caucasus named Derial, 136 miles S.E. of Stavropol, and 148 N.N.W. of Tiflis. It is built principally of wood and clay, and the houses are in general no more than one storey high; but the numerous and beautiful gardens which the town contains give it an appearance of great cheerfulness. There is a Greek and a Roman Catholic church, the latter of which is a fine edifice. The inhabitants depend chiefly on the produce of their gardens and vineyards. Manufactures of leather and brandy are also carried on to some extent. Mozdok has also a considerable trade with Georgia and the other parts of Russia. Pop. (1849) 10,869.

MOZUFFURNUGGUR, in Hindustan, a British district in the lieutenant-governorship of the N.W. provinces, extending from N. Lat. 29. 10. to 29. 50., E. Long. 77. 6. to 78. 10. It contains an area of 1617 square miles, and a population of 672,861. The tract was ceded to the East India Company by the Mahratta chieftain Scindia in 1803. The town of Mozuffurnuggur is situated in N. Lat. 29. 28., E. Long. 77. 45.

MSTISLAVL, a town of European Russia, in the province of Moghilev, is situated on the right bank of the Vekhra, 55 miles E.N.E. of Moghilev. It contains six churches and a synagogue, several convents, and a college formerly belonging to the Jesuits. Linen is manufactured here; and an active trade is carried on with Riga in corn, hemp, and flax. This province formed a part of the ancient duchy of Lithuania. Pop. (1851) 6675.

Mudge

||
Muggleton.

MUDGE, WILLIAM, one of the superintendents of the grand trigonometrical survey of England and Wales, was born at Plymouth in 1762. He was one of a race of gifted men. His grandfather, the Rev. ZACHARY MUDGE, was an intimate friend of Dr Johnson, and the author of a well-known volume of sermons; his uncle, THOMAS MUDGE, was pronounced by the scientific men of his day to be "one of the first watchmakers which this country has produced;" and his father, Dr JOHN MUDGE, is known in the history of science as the improver of the reflecting telescope. William Mudge was trained for the army in the Royal Military Academy at Woolwich, and served abroad as a lieutenant in the Royal Artillery. It was after his return to England that he was appointed to assist in the trigonometrical survey under the superintendence of Lieutenant-Colonel Edward Williams, R.A. The rank of captain was then conferred upon him. In course of time he became superintendent, and was raised to the successive dignities of major, lieutenant-colonel, and major-general. The results of his surveys were published from time to time in the *Philosophical Transactions*, and secured for him much distinction. He was elected a correspondent of the Institute of France, and a fellow of the Academy of Sciences at Copenhagen and of the Society of Antiquaries at London. During the latter part of his life he also held the office of lieutenant-governor of the Royal Military Academy at Woolwich. He died at London in April 1821.

MUFTI, the name given to the head doctors of the law of the Koran in Turkey, of whom there is one in every large town. The authority of the mufti is very great in the Ottoman empire; for even the Sultan himself, if he would preserve any appearance of religion, cannot, without hearing his opinion, put any person to death, or so much as inflict any corporal punishment. In all actions, especially criminal ones, his opinion is required by giving him a writing in which the case is stated under feigned names, and which he subscribes with the words, "He shall (or shall not) be punished," without assigning any reason for his judgment. Such outward honour is paid to the mufti, that the Grand Signior himself rises up and advances seven steps to meet him when he comes into his presence. The mufti of Constantinople, or "Sheikh-ul-Islam" (Chief of the Elect), is the chief functionary of the Turkish church, and has a jurisdiction over the muftis of the provinces. He holds his office at the will of the Sultan.

MUGGLETON, LUDOWICK, the founder of the sect of the *Muggletonians*, was born in 1609, and was bred to be a tailor. Abandoning his trade in 1651, he set up himself and his companion John Reeves as the "two last witnesses" mentioned in the Apocalypse as having power to prophesy and to smite mankind with plagues. They began to fulfil their "commission" by denouncing all religious sects, and especially the Ranters and the Quakers. An exposition of their doctrines was published in 1656 under the title of *The Divine Looking-Glass*. In this work, among other wild vagaries, were propounded the views that the Trinity are merely the three different names, and not the three distinct persons, of one God; that God has a real human body; and that he left Elias as his vicegerent in heaven when he came down to the earth to die on the cross. Such profane heresies provoked much opposition. They were attacked by the famous Quaker William Penn in a book entitled *The New Witnesses proved Old Hereticks*, 4to, 1672. Muggleton himself, in 1676, was arraigned at the Old Bailey on the charge of blasphemy. He died in March 1698. His collected works were published in 1756. In 1832 appeared a complete collection of the works of Reeves and Muggleton, together with tracts by others of the same sect, in 3 vols. 4to.

Muhalic
||
Mulcaster.

MUHALICH, or MIKALITZA, a town of Asiatic Turkey, in the pashalic of Anatolia, is situated in a plain near the confluence of the Susuelu and the Ulubad, about 15 miles from the mouth of the united stream, which takes the name of Muhalic, and 35 miles W.N.W. of Brusa. The town contains nine mosques and several khans, and is chiefly inhabited by Greeks and Armenians. It has a considerable trade in silk produced in the neighbourhood, and in the melons and other vegetables which are conveyed by water from the east shore of Lake Apollonia, down the Ulubad, to Muhalic, and thence by the Muhalic River and the sea to Constantinople. Pop. about 11,000.

MÜHLENBACH, or MÜHLBACH, a town of Transylvania, is situated on a river of the same name, 12 miles S. of Alba Julia, and 30 W.N.W. of Hermannstadt. It is surrounded by walls, beyond which there are two suburbs; and is defended by two regularly-built forts. There are here a Lutheran and a Catholic church, a Franciscan convent, and a Protestant school. Weaving is the principal branch of industry carried on; and there is a considerable trade in wine. Pop. 4200.

MÜHLHAUSEN, a town of Prussia, in the government of Erfurt, pleasantly situated on the Unstrut, 29 miles N.W. of Erfurt. It is surrounded by walls with towers, and was formerly a free town of the empire. It has four churches, of which the High Church is the most handsome; a high school; and several hospitals and other benevolent institutions. Manufactures of leather, linen and woollen fabrics, and tobacco are carried on; and there are also breweries and distilleries in the town, and copper and iron mines in the neighbourhood. Mühlhausen was in 1524 the head-quarters of the Anabaptist rebel and fanatic Munzer, who excited to insurrection a large number of peasants from the surrounding country. The town preserved its liberty and popular government till 1802, when it was ceded to the kingdom of Prussia, to which it has since belonged. Pop. 13,723.

MULA, a town of Spain, province of Murcia, 22 miles W. of that town. It contains a great square, wherein are built a town-house, prison, and clock-tower; besides which are also an hospital, a theatre, a nunnery, and several churches. The manufactures of the place include pottery, copper, soap, wool, and brandy. Pop. 6500.

MULCASTER, RICHARD, a distinguished scholar of the sixteenth century, was born at Carlisle about 1535. He received his elementary education at Eton under the celebrated Udal, and entered King's College, Cambridge, in 1548. He removed to Christ Church, Oxford, in 1555, and took his degree in arts during the following year. He began to teach in 1559, and from his great reputation for philological attainments, was chosen in 1561 first master of Merchant Tailors' School, London, then just established. For a period of twenty-five years he continued "to fill St John's College, Oxford, with excellent scholars;" and in the Latin plays acted before Queen Elizabeth and James I. at Oxford, the pupils of Mulcaster carried the palm. Fuller tells us that Mulcaster was a severe teacher, but much beloved by his pupils. After being connected for some time with St Paul's School, he was promoted to the rectory of Stanford-Rivers in Essex, where he died in 1611. Many of his panegyrics in Latin verse were prefixed to the works of his contemporaries. His works are,—*Positions, wherein those Primitive Circumstances be examined which are necessarie for the training up of Children, either for Skill in their Book, or Health in their Bodie*, London, 1581, 4to, which did carry him on to promise, and bind him to perform, *The first Part of the Elementaries which entreateth chiefe of the Right Writing of our English Tongue*, London, 1582, 4to, a work of which Warton speaks highly; also a *Catechismus Paulinus in usum Scholæ Paulinæ conscriptus*, London, 1601, written in long and

short verse, and once very popular. (Warton's *History of English Poetry*, vol. iii., p. 282, 1840; and Wilson's *History of Merchant Tailors' School*, vol. i.)

MÜLHEIM-AM-RHEIN, a town of Rhenish Prussia, in the government of Cologne, and 3 miles N.E. of that town, is situated on the Rhine, which is here crossed by a suspension-bridge. It contains two churches and a synagogue. The manufactures of the place are extensive, consisting of leather, silk, cotton, candles, soap, tobacco, brandy, &c.; and there is also an active trade in corn and timber. The activity and prosperity of the town are chiefly owing to its Protestant citizens, who came hither from Cologne in the beginning of the seventeenth century. Pop. 5643.

MÜLHEIM-AM-RUHR, a town of Rhenish Prussia, in the government of Dusseldorf, is built on the Ruhr, which is here crossed by a suspension-bridge, 15 miles N.N.E. of Dusseldorf. It contains three churches and a synagogue. The manufactures are considerable, consisting of cloth, paper, soap, starch, tobacco, gunpowder, machinery, &c.; and there is a coal mine in the neighbourhood which furnishes the principal article of trade. The River Ruhr is navigable as far as this town. Pop. 10,181.

MULHOUSE, or MÜLHAUSEN, a town of France, in the department of Upper Rhine, on the Ill, 27 miles S. of Colmar, 61 miles S.S.W. of Strasburg, and 16 N.W. of Basle. It consists of an old and a new town,—the former standing on an island of the Ill, and approached by several bridges; the latter, on the right bank of that river, lying between it and the Rhine and Rhone Canal. The old town is irregularly but well built, and the streets are broad, well paved, and clean. The principal buildings are the Roman Catholic and Protestant churches, synagogue, town-hall, school, arsenal, and hospital. The new town is handsomely and regularly built; and contains an exchange, a chamber of commerce, a hall belonging to the Society of Industry, and many other fine houses. Mulhouse is one of the greatest manufacturing towns of France. The principal articles produced are muslins and cotton prints, of which probably a greater quantity is made here than in any other place in the world. This branch of manufacture was not introduced here till 1746, and has contributed very much to the great and rapid progress of the town since that time. Cotton-spinning is also extensively carried on; but in this branch the manufacturers of Mulhouse cannot compete with those of Manchester and Glasgow, and the manufacture also labours under the disadvantage of the necessity of the raw material being conveyed from Havre or Marseilles. The supply of coal is also difficult to obtain, as it has to be brought from some distance by the Rhine and Rhone Canal. The other manufactures of Mulhouse consist of woollen cloth, silk, linen, hosiery, paper, leather, beer, &c.; and the trade is considerable in the produce of the manufactures, as well as in corn, wine, brandy, raw cotton, &c. Mulhouse has a court of commerce, a chamber of manufactures, and a council of *prud'hommes*. It was formerly the capital of a small independent republic in alliance with the Swiss cantons, but was united to France in 1798. Mulhouse is remarkable as the birthplace of Lambert the mathematician, born in 1728. Pop. (1851) 28,142.

MULL ISLAND, one of the Western Isles of Scotland, Argyllshire, bounded W. by the Atlantic; N. by the same and Loch Sunart; N.E. by the Sound of Mull, a narrow strait which divides it from the mainland; and S.E. by the Atlantic; N. Lat. (of centre) 56. 30., and W. Long. 6. 4. It is of an irregular shape, deeply indented on the west by Lochs Na Keal and Seriden, as well as by numerous smaller inlets round its entire coast-line, and measures 29 miles in length, by from 24 miles of maximum breadth to 3½ miles at the head of Loch na Keal. The coast is rocky, and the surface rugged and covered in some parts by extensive tracks of moorland. With the exception of a

Mülheim-
am-Rhein
||
Mull.

Müller. narrow belt of limestone on the S., the entire rock of Mull belongs to the ignigenous system of rocks, especially of trap, which on the western coast presents numerous horizontal terraces; while at its S.W. extremity a fine whitish granite occurs, used in the construction of the Skerryvore lighthouse. A Tertiary stratum, however, has been lately found between the newer trap deposit and that of an earlier date. Many caverns occur round the shores of the island, varied here and there by castles and columns of basalt. The interior, however, presents no aspect of interest, excepting Ben More, which rises to 3097 feet. The soil is almost wholly devoted to pasturage, the only spots where grain is grown being in the more sheltered spots near the coast. Excellent sheep and small hardy cattle are reared here for the lowland markets. The farms have recently been much enlarged at the expense of the small holders, who have since 1841 left the island in considerable numbers. In its climate Mull resembles the neighbouring islands, being mild and humid, and subject to severe storms from the S.W. A considerable number of the inhabitants are employed in the herring fishery; while abundance of white fish is to be had round the coast. The island is divided into the three parishes of Torosay, Kilninian and Kilmore, and Kilfinichen and Kilvickeon. The amount of poor rates collected here in the year ending May 14, 1856, amounted to L.2269, against L.2049 expended; and there were in the same year 432 persons who received relief. Pop. of island (1841), 10,064; (1851), 8369, of whom 4243 were females. (For the history of Mull, see HEBRIDES.)

MÜLLER, GERHARD FRIEDRICH, a German traveller and author, was born at Herford in Westphalia in 1705. By Professor Mencke, under whom he studied at Leipsic, he was recommended to the government of Russia. Having been admitted into the newly-founded Academy of St Petersburg, he taught Latin, history, and geography, and was afterwards promoted to the chair of history. His unwearied devotion to his duties, and his elegant scholarship, soon recommended him to higher appointments. Employed in 1740 to accompany De Lisle into Siberia, he spent ten toilsome years in studying the geography and antiquities of that barbarous and desert country. Soon after his return he was nominated historiographer to the Russian empire. The office of keeper of the archives was added in 1766. He was next appointed to draw up a collection of the diplomatic treaties of Russia, on the model of the *Corps Diplomatique* of Dumont. In the discharge of all these duties he acquired a knowledge of the history of the empire equally minute and extensive. His unflagging industry embodied that information in a number of works which have proved an inexhaustible source of information to succeeding annalists, and which entitle their author to the appellation of the "father of Russian history." Müller died in October 1783. His principal work is a *Collection for the History of Russia*, in 9 vols. 8vo, St Petersburg, 1722-64.

MÜLLER, Johann, surnamed, from the Latinized name of his native place, *Regiomontanus*, the greatest mathematician of the fifteenth century, was born in 1436 at Königsberg, but whether at the town of that name in Franconia or in Prussia is disputed. At the age of twelve he was sent for his education to Leipsic, and at the end of four years he rivalled his teachers in arithmetic, geometry, and astronomy. His studies were next prosecuted under Peurbach, the astronomical professor in Vienna. Here his talents and acquirements recommended him to the notice of his teacher and the celebrated Cardinal Bessarion. On the death of the former in 1461, he was appointed to the vacant chair, and was encharged with the completion of a new translation of Ptolemy's *Almagest* which had been begun by the deceased professor. But before entering on these arduous tasks he repaired to Italy, to acquire a thorough knowledge of the Greek language. While study-

ing philology at Rome, Ferrara, and Padua, he was also engaged in writing his *De Triangulis*, a treatise which proved an important acquisition to trigonometrical science. Shortly after 1464 he returned to Venice. Before, however, his stay in that city had been prolonged over many years, an invitation from the King of Hungary drew him to Buda. There his time was employed in constructing his *Tabula Directionum Projectionumque*, &c., a work which was afterwards printed in 1475, and which contained the first table of tangents ever published in Europe. A great stimulus was given to his studies by his removal to Nuremberg in 1471. By a wealthy inhabitant of that town named Bernard Walter he was supplied with astronomical instruments and with a printing-press. He was thus enabled to carry on that important series of observations which were continued after his death by Walter, and which were long afterwards, in 1544, published under the title of *Observationes Triginta Annorum*, 4to, Nuremberg. Another important work which he produced about this time was the *Kalendarium Novum* for the three years 1475, 1494, and 1513. It passed into Hungary, Italy, France, and England, was speedily sold off, and increased the fame of its author. In 1475 he was appointed archbishop of Ratisbon, and was invited to Rome by Pope Sixtus IV. He had only lived a year in that city when he was cut off, at the age of forty. His remains were interred with great honour in the Pantheon. Gassendi appended a *Life of Müller* to his *Life of Tycho Brahe*, 4to, Paris, 1654. (For an account of the services of Regiomontanus to the cause of science, see DISSERTATION IV., § i.)

MÜLLER, Johann, an eminent Swiss historian, was the son of a clergyman, and was born at Schaffhausen in Switzerland in 1752. He received his elementary education at the gymnasium of his native town, and was early intended for the church. But chancing to be sent to the university of Göttingen, he acquired, under the tuition of Schloezer, an irresistible bias towards historical studies, and published at the age of twenty a *History of the Cimbric War*. His classical acquirements were also considerable, and procured for him the appointment to the Greek chair at Schaffhausen. This position, however, his desire for a society more learned than that of his native town soon induced him to abandon. He repaired to Geneva in 1774, and there he lived for six years, writing a course of lectures on universal history, meditating his great historical work on the Swiss confederation, and enjoying the society of his bosom friend Bonstetten. In 1780 he set out for Germany. His fame had gone before him. Frederick the Great tried in vain to attach him to the Academy of Berlin; and the landgrave of Hesse placed him in the chair of history at Cassel in 1781. Meanwhile, in the previous year the first volume of his *Geschichte der Schweizerischen Eidgenossenschaft* had appeared at Berne. It was characterized by dignity of style, depth of research, and liberality of sentiment, and it speedily came to be considered the master-work of its author. In 1783 the shifting propensity of Müller led him to abandon his professorship, and he returned to Switzerland to live in the house of Bonstetten. He was nominated in 1786 a counsellor to the elector of Mentz, and continued in this capacity to occupy himself with politics till the occupation of that city by the French in 1792. The next twelve years were spent at Vienna under the patronage of the emperors Leopold II. and Francis II. Then he repaired to Berlin, and accepted a place in the Academy of that city. His mind had now thrown off those political engagements which had so long detained it from its proper province, and began to be occupied with a projected *Life of Frederick the Great*. But before he could accomplish anything more than the plan, the subjugation of Prussia by the French in 1806 diverted him once more from his literary studies. Bona-

Müller.

Müller. parte during his stay at Berlin took notice of him, and in 1807 appointed him secretary of state to the new kingdom of Westphalia. This office was soon exchanged for that of director-general of public instruction. Müller applied himself to his new duties with all his wonted ardour, but success did not seem likely to follow. His health sank under anxiety and intense exertion, and he died at Cassel in May 1809. His complete *History of the Swiss Confederation*, bringing the narrative down to the end of the fifteenth century, had been published at Leipsic in 1786, and had been translated into French by Labaume, in 12 vols. 8vo, Lausanne, 1795-1803. A collection of his works was published in 27 vols. 8vo, Tübingen, 1810-19.

MÜLLER, *Johann Friedrich Wilhelm*, an eminent German engraver, son of Johann Gothard von Müller, was born at Stuttgart in 1782. Under the able tuition of his father he made notable progress in his art, and at the age of twenty had executed several excellent engravings of portraits. He was then sent to Paris to prosecute his studies in the Academy, and to perfect his taste among the master-works of art in the Louvre. With a devotion that endangered his health, he applied himself to his profession. His cunning hand soon acquired the auxiliary art of painting. He produced engravings of the statue of "Venus d'Arles," and of several portraits. At length, in 1808, his print of Domenichino's "St John" established his fame. Immediately afterwards he undertook to engrave for a printseller the "Madonna di San Sisto" of Raphael in the Dresden gallery. All his energies were forthwith summoned to the task. After visiting Italy for the purpose of becoming more intimate with the works of the great master whom he was about to copy, he settled down at Stuttgart to steady and long-continued labour. The professorship of engraving at Dresden was conferred upon him in 1814. But change of residence did not produce any change in his application. Day and night he was absorbed in studying and transcribing the great masterpiece of painting before him. At length the engraving was completed, and despatched to Paris to be printed. Müller soon after fell into a hopeless state of debility, and died on the 3d May 1816, several days before his plate reached its destination. The engraving on which his life had been sacrificed is pre-eminently his masterpiece. His other works, chiefly portraits, include likenesses of William, King of Wurtemberg, Jerome Bonaparte, Jakobi the poet, Professor Hebel, Dr Hufeland, and Schiller. He also executed a medallion of Napoleon.

MÜLLER, *Johann Gothard von*, a German engraver, was born at Bernhausen in Wurtemberg in the year 1747, and was educated at the college of Stuttgart. He was intended at first for the church, but his own strong bias towards the study of design ultimately decided his profession. He became a pupil of the court painter, Guibal, in 1764. Yet his talents soon appeared to be more fitted for engraving than for painting; and therefore, by the advice of his master, he resorted to Paris in 1770 to study under the engraver Wille, a countryman of his own. He continued there until he had become a proficient in his art, had gained several prizes, and had been elected a member of the French Academy. Then an invitation from Duke Karl summoned him to Stuttgart in 1776 to teach engraving. After being settled here for more than nine years, he was recalled to Paris to engrave a portrait of Louis XVI. This work, and an engraving of Trumbull's "Battle of Bunker's Hill," were his chief productions during his second sojourn in Paris. On his return to Stuttgart in 1802, he was appointed professor of his art in that city, and experienced the gratification of seeing his own son Johann Friedrich far outstrip the rest of his pupils. His fame was now established, and honours flowed in upon him. He was elected a member of the several academies of Berlin, Vienna, Munich, and

Copenhagen; and he received from the government of Wurtemberg the Order of Civil Merit in 1808, and a knighthood in 1818. Yet his industry in the prosecution of his art did not slack. He was engaged in engraving a series of portraits of celebrated contemporaries, when the debility of an advanced age forced him to retire from his profession. His death took place at Stuttgart in March 1830. His engravings are chiefly portraits, and include a likeness of Schiller after A. Graf.

MÜLLER, *Karl Ottfried*, an eminent writer on the mythology and history of Greece, was the son of a chaplain in the Prussian army, and was born at Brieg in Silesia in 1797. After attending the gymnasium of his native town, he entered the university of Breslau in 1813, and began to study at Berlin in 1815. In 1817 a little treatise, entitled *Algineticorum Liber*, betrayed the depth of his mythological knowledge, and laid the foundation of his fame and fortune. Two years afterwards, when scarcely twenty-one, he was promoted to a chair in the university of Göttingen. Here he continued for more than twenty years to lecture on archæology and art, and to produce works with a rapidity which sometimes entailed carelessness and false generalizing. In 1820 his *Orchomenos and the Minyans* appeared, and communicated to philological studies in Germany an impulse which was felt in the course of time throughout the rest of Europe. By his method of analyzing the mythical cycles, and thus detecting the historical elements around which these had grown, he bade fair to evolve a history of Greece of the same satisfactory nature as Niebuhr's *History of Rome*. He continued to follow out this plan in his *Dorians*, published at Breslau, in 2 vols. 8vo, 1824. The new and striking feature in this work was the attempt to show that the natives of Doris were the happiest, the wisest, the bravest, and the best of all the Greek races. Such a view, so directly opposed to the received opinions, contributed in no small degree to secure for the book a European reputation. It was hailed, even by those who dissented from its novel opinions, as a cheering improvement on the dull round of those compilations that had hitherto been palmed off upon the world as histories of Greece. An English translation by H. Tuffnell and G. C. Lewis, with emendations and additions by the author himself, appeared at Oxford in 1830. Prevented by certain scruples from advancing any further in the path of investigation which he had hitherto pursued so successfully, he had published a great work, entitled *The Etruscans*, in 2 vols. 8vo, 1828. His *Manual of the History of Ancient Art* appeared at Breslau two years afterwards. This work, characterized in an especial degree by his usual keen thinking, curious research, and forcible style, was considered one of his finest productions, and passed through a second edition in 1835. All this time his restless and rapid intellect was producing numerous articles for periodicals and encyclopædias, and was planning a History of Greek Literature. The first volume of this work appeared at Göttingen in 1839, and was translated into English soon afterwards. Müller now laid aside his pen. He had long desired to visit that land whose poetry and mythology had been his life-long study, and whose rich scenery and glorious sky had so often passed before the eye of his imagination. Accordingly he set out for Greece in 1839. On his arrival his bodily activity was as enthusiastically exercised as his intellectual in searching for the remnants of antiquity. During the heat of a July day, while conducting an excavation among the ruins of Delphi, he was seized with a fever. He was conducted to Athens, and died there on the 1st August 1840. An appropriate resting-place was found for this great Hellenistic scholar in the precincts of the old academy. His merits were celebrated by Lücke in a work entitled *Erinnerungen an Karl-Ottfried Müller*, 8vo, Göttingen, 1841.

Müller.

Among the works of Müller which have not been mentioned above are,—*Minervæ Poliadis Sacra et Ædem in Arce Athenorum illustravit M.*, 4to, Göttingen, 1820; *On the Abode, the Descent, and the Ancient History of the People of Macedonia*, 8vo, Berlin, 1825; *De Phidiæ Vita et Operibus*, 4to, Göttingen, 1827; and editions of the *Eumenides* of Æschylus, 4to, Göttingen, 1833, the *De Lingua Latina* of Varro, 8vo, Leipsic, 1833, and the *De Verborum Significatione* of Festus, 8vo, Leipsic, 1839. His *History of the Literature of Greece*, composed of the volume which had appeared in his lifetime and the volume which he had left unfinished, was edited by his brother, in 8vo, Breslau, 1841. The *Dorians* and the *Orchomenos and the Minyans* were published together by F. W. Schneidewin, under the title of the *History of Hellenic Races and Cities*, in 3 vols., Breslau, 1844.

MÜLLER, *Othon Frederik*, an eminent Danish naturalist, was the son of poor parents, and was born at Copenhagen in March 1730. He commenced to study for the church, and supported himself by the exercise of his musical talents. His learning, and the strength of his moral character, soon raised him to notice. He was appointed tutor to the young Count Schulin in 1753. It was the advice of his pupil's mother, a woman of great penetration, that induced him to turn his attention to natural history. With all the determination and concentrative power of his character, he commenced his new studies. He examined patiently both animals and plants, executed exact sketches of them, and wrote a Danish treatise on Fungi, and two Latin works respectively entitled *Fauna Insectorum Friedrichsdaliana*, and *Flora Friedrichsdaliana*. At the same time his travels through different countries with his pupil were affording him an excellent opportunity for extending his scientific observations, and for becoming intimate with other naturalists. After his return to Copenhagen in 1767, a high rank in the general estimation was assigned to him. He was honoured with several titles, he was installed in several important offices, and he was appointed to continue the *Flora of Denmark*, a great work which had been begun by Oeder in 1761 by the command of Frederic V. An advantageous marriage soon afterwards enabled him to resign his official appointments, and to consecrate all his efforts to his favourite study. He first turned his observation upon those annulose animals which are called by Linnæus "Aphroditæ and Nereides." His numerous and interesting discoveries on the structures and habits of these creatures were given to the world in a work entitled *On Certain Worms found in Fresh and Salt Water*, 4to, Copenhagen, 1771. Even more successful were his studies on the Infusoria. By the patient employment of powerful microscopes he discovered many new species, and was the first among naturalists to attempt the extremely delicate task of arranging these animalcules into distinctive genera. His observations in this field of inquiry were published in his *Vermium Terrestrium et Fluviatiliū seu Animalium Infusorium Helminthecorum et Testaceorum non Marinarum succincta Historia*, 2 vols. 4to, Copenhagen and Leipsic, 1773-74. The attention of Müller was next occupied with the Hydrachnæ or water-spiders. He was the first who discovered that these animalcules swarm by millions in all our fresh-water streams. His treatise on them was carefully written in lucid and elegant Latin, was copiously illustrated with faithfully-executed plates, and was published at Leipsic in 1781, under the title of *Hydrachnæ in Aquis Daniæ Palustribus detectæ et descriptæ*. He was in the midst of his favourite investigations when he was cut off by death on the 26th December 1784. Two posthumous works, the one on the Entomonstraca, small crustaceans belonging to Linnæus' genus of the Monoculi, and the other on the Infusoria, were published in 1785 and 1786 respectively. Müller had commenced in 1779 the

Zoologia Danica, a gigantic work which was continued first by Abildgaardt and afterwards by Rathke. The two parts which he wrote were reprinted in 1788.

"The three works on the Infusoria, Monoculi, and Hydrachnæ," says Cuvier in the *Biographie Universelle*, "have procured for Müller a place in the front ranks of those who have enriched science with original observations."

MÜLLER, *Wilhelm*, a German poet, was the son of a mechanic, and was born at Dessau in 1795. After studying philology and ancient German literature at the university of Berlin, and serving in the Prussian army in the campaign of 1813, he devoted himself to the cultivation of his literary tastes. He produced his *Blumenlese aus den Minnesängern* in 1816, and a translation of Marlowe's *Faustus* in 1818. About this time a sojourn which he made in Vienna afforded him an opportunity of acquiring modern Greek. Soon after his return he was appointed classical teacher in the newly-established school of Dessau, and keeper of the ducal library. His undivided attention was now given to the composition and study of poetry, and his works appeared in quick succession. He published his *Gedichte aus den hinterlassenen Papieren eines reisenden Waldhornisten* and *Homerische Vorschule* in 1824, his *Lieder der Griechen* in 1825, and his *Bibliothek Deutscher Dichter des 17 Jahrhunderts* in 1822-27. He was also a contributor to several periodicals and encyclopædias. Müller died in 1827. A collection of his works, accompanied with a Life, was published by the poet Schwab, in 5 vols., Leipsic, 1830.

MÜLLER, *William John*, an eminent English landscape and costume painter, was the son of a German, and was born at Bristol in 1812. He was instructed in landscape-painting by J. B. Pyne, and was greatly assisted in the study of his art by a knowledge of natural history, which he acquired from his father, the curator of the Bristol Museum. His most valuable lessons, however, were received in the great school of nature. Setting out in 1833, he travelled with unwearied enthusiasm through Germany, Switzerland, and Italy, studying devotedly every feature of the striking landscapes through which he passed, and enriching his portfolio with numerous valuable sketches. On his return to his native place in 1834, the progress he had made in his art was not great enough to satisfy himself. He therefore spent 1838 and 1839 in wandering amid the colossal remains of Egyptian architecture and the classic scenes of Greece. His pictures of "Athens" and "The Memnon," completed after his return, and exhibited in the Academy in 1840, proved that he had now attained the skill of a master-artist. They brought him into notice, and were the means of procuring for him employment in London. Two years afterwards, his "Picturesque Sketches of the Age of Francis I." carried his fame beyond his own country. Yet his ardent striving after perfection did not flag. He accompanied the Lycian expedition of Sir C. Fellows in 1843. The results of this tour, consisting of five pictures, were sent to the Royal Academy's exhibition of 1845; but happening to be hung in a disadvantageous position, they failed in a great measure to strike the spectators. This misfortune deeply wounded his sensitive and sanguine temperament, and prostrated his previously impaired constitution. He died of heart disease at Bristol in September 1845.

MULLINGAR, a market-town of Ireland, capital of the county of West Meath, is situated on the Brosna, 44 miles W. by N. of Dublin, with which it is connected by the railway to Galway and by the Royal Canal. The principal street, which is about a mile in length, extends from E. to W., and the other streets and lanes extend in different directions from it. The houses are well built of stone, and covered with slates. The principal buildings are,—the parish church, with a tower and spire; a large and hand-

Müller
||
Mullingar.

Mummy
||
Munday.

some Roman Catholic church; Presbyterian and Wesleyan churches; a court-house, jail, infirmary, and nunnery; barracks for 1000 soldiers; and several schools. Tanning and brewing are carried on; and wool constitutes the principal article of trade. Mullingar formerly sent two members to the Irish Parliament, but was disfranchised at the Union. A weekly market is held here on Thursdays; and there are four annual fairs. Pop. 5026.

MUMMY, a body embalmed, or dried and preserved in the manner practised by the ancient Egyptians. There are two kinds of bodies denominated *mummies*. The first are only carcases dried by the heat of the sun, and by that means preserved from putrefaction. Some well-known specimens of this class of mummies are to be found in the church vaults of Strasburg, Toulouse, and Bordeaux. The second kind of mummies are bodies taken out of the catacombs in which the Egyptians deposited their dead after embalming. (See EMBALMING; also Sir G. Wilkinson's *Ancient Egyptians*, vol. ii.)

MUNCHHAUSEN, HIERONYMUS KARL FRIEDRICH VON, the original of Bürger's wonder-narrating hero, was a German officer about the beginning of the eighteenth century. He entered the Russian army, and served in several campaigns against the Turks. An irresistible propensity towards exaggeration was his ruling passion. Accordingly, on his return to Germany, he was wont to describe, with all the intense earnestness and minute particularizing of a true narrator, the prodigious feats he had done in Turkey. It was at Pyrmont that the poet Bürger happened to be one of his auditors, and to hear some of those extravagant fictions which afterwards formed the groundwork of the humorous *Wunderbare Abenteuer und Reisen des Herrn von Münchhausen*. The hero of the book was very much enraged and chagrined at the notoriety which soon became attached to his name. He died in 1797.

MUNDAY, ANTHONY, an English dramatist of the age of Shakspeare, was born in 1553. After having been successively a stage-player and an apprentice, he visited Italy, and was a student, or, as he himself called it, "the Pope's scholar," in the English college at Rome. On his return he became connected with the theatres, both as an actor and as a writer. His ready pen was also employed by the booksellers in compiling and in writing pamphlets. *The Mirrour of Mutabilitie*, a tract published in 1579, was the first of a series of ephemeral prose works which began to proceed from his hand. Several of these were devoted to the confutation of Popery, the religion in which he had been trained, and from which he had been recently converted. But not until the close of the sixteenth century did Munday attain his celebrity as a dramatist. He then wrote several dramas in conjunction with other authors, especially Chettle and Drayton. One of the most popular of these, *The Death of Robert, Earl of Huntingdon*, is enlivened by a gay and spirited description of Robin Hood's life in "merrie Sherwood." Shortly after this period he became a city poet and a composer of city pageants. In this office he seems to have found his proper sphere; for Meres calls him "the best plotter," and Webbe mentions him as having written "very excellent works, especially upon nymphs and shepherds, well worthy to be viewed and to be esteemed as rare poetry." He even became a worthy object for the envy of Ben Jonson, and was ridiculed, in the character of Don Antonio Ballendino the pageant-poet, in *The Case is Altered*. Towards the close of his life Munday appears to have held a respectable position as a tradesman, since he was fond of styling himself, on the title-pages of his later works, "citizen and draper of London." His death took place in August 1633, and he was buried in St Stephen's church, Coleman Street. A monument was erected over his grave. Fourteen of the dramas which Munday contributed to write are enumerated, and two of them are re-

printed in Collier's supplementary volume to Dodsley's *Münden*
||
Old Plays. Munich.

MÜNDE, a walled town of Hanover, in the government of Hildesheim, is situated between the Fulda and Werra, which unite below the town and form the Weser, 14 miles W.S.W. of Göttingen. The principal buildings are the church of St Blaise, an edifice of the fourteenth century; and the old castle, founded in 1571 by Erich II., Duke of Brunswick-Lüneburg. There are also two other churches, a synagogue, and several schools. Leather, beer, and brandy are manufactured here; and the Weser is navigable up to the town, where there is a harbour, by which a considerable trade was formerly carried on. The town was also in former times a great seat of the linen trade. Pop. 5900.

MUNDEN, JOSEPH SAUNDERS, a distinguished comedian, was born in London in 1758. Becoming an apprentice to a law-stationer, he was employed in writing out the parts of actors, and in course of time was smitten with an irrepressible fondness for the histrionic art. He made his first appearance as a player on the stage of a strolling company. His humour, venting its exuberance in the drollest grimaces, and deepening often into the most touching pathos, gradually came to be appreciated. After acting for some time in the Canterbury theatre, he appeared before a London audience in 1790. For the next twenty-three years he was the comic favourite at Covent Garden. He was then transferred to the stage of Drury Lane, and continued to win fresh laurels, especially by his impersonation of "Old Dornton" in *The Road to Ruin*. He retired from the stage in May 1824, and died in February 1832.

MUNDI, in Hindustan, a tract of the Punjab, comprising several valleys, with their inclosing ridges, on the southern slope of the Himalayas, and containing an area of 759 square miles, with a population of 113,000. Upon the conquest of the Punjab, Mundi became tributary to the British; and upon the death of the rajah in 1851, and the succession of his infant son, arrangements were made for the government of this petty state. Mundi, the capital town, which is situated at the confluence of the Sukyt with the Beas, is in Lat. 31. 43., Long. 76. 58.

MUNDINGOES, or MANDINGOES. See MANDINGO.

MUNDOTE, in Hindustan, a tract of country in the British province of Sirhind, extending along the left bank of the Sutlej, and containing an area of 780 square miles, with a population of 116,000. It was held by a Patan chief, whom it has recently been found necessary to depose, in consequence of the oppressive and tyrannical character of his government. The town of Mundote is in N. Lat. 30. 53., E. Long. 74. 26.

MUNEPOOR, in Hindustan, a native state on the eastern frontier of India, 125 miles in length and 80 in breadth, and containing an area of 7584 square miles. The principality was taken under British protection previously to the breaking out of the first Burmese war, and under the treaty of Yandabhoo, concluded in 1826, the King of Burmah renounced all claim to the territory. It pays no tribute to the British. Muneepoor, the chief town, is situated in N. Lat. 24. 49., E. Long. 94. 1.

MUNICH (Ger. *München*), a town of Germany, capital of the kingdom of Bavaria, and the seat of an archbishop, stands on the left bank of the Isar, 1650 feet above sea-level, and 225 miles W. of Vienna; N. Lat. 48. 8. 40., and E. Long. 11. 34. 40. It is situated in the middle of an uninteresting plain, bounded on the E. by a range of low hills, and on the S. by the Tyrolese Alps, which rise to a considerable height some 20 miles from the town. Their contiguity, coupled with the great elevation of Munich, render it very subject to sudden changes, as well as to extremes of temperature. The city consists of an old and new town, the former occupying the centre round which the new town or suburbs

Munich. have been erected. These are six in number, and comprise the Ludwig, Max, and Schoenfeld suburbs, on the W., N., and E.; the Isar and St Anna's suburbs, between the old town and the river, and the Au suburb, on the other side of the same. Great additions have been made to Munich during the last fifty years. Possessing neither manufactures nor trade of any importance, it owes its increase solely to the amount of court favour bestowed on it; and now there are few, if any, towns in Europe of the same size which contain so many public edifices and institutions devoted to the purposes of art and science, as this the capital of Bavaria and acknowledged metropolis of Southern Germany. The streets of the old town are generally straight, but many of them are narrow, and the houses exceedingly lofty and quaint-looking. In the suburbs, on the other hand, the streets have been laid out at right angles, and the houses are more modern in appearance. From the extent of ground devoted to those environs, however, many of the streets and squares are not fully occupied by houses, but display frequent gaps. Between the suburbs and the old town there are several open places occupying the site of the old walls; the principal are Maximilian's and Karl's squares. Of the old ramparts, the only remnants are several of the gates. Among the numerous public buildings which give character to the town, the churches are first worthy of remark. The Frauenkirche, or cathedral, commenced in 1468, is built about the centre of Munich, off the Kaufinger Strasse, the main street of the town. It is a plain, massive building of brick, with two towers surmounted by domes, each rising to the height of 336 feet. The nave of the church measures the same length as the towers, and is 170 feet in breadth; while the windows are 66 feet in height. A number of small chapels, formed by the buttresses, which in this edifice are brought within the building, are ranged round its sides. In front of the altar is the mausoleum of Ludwig IV., Emperor of Germany, erected in 1622 by the Elector Maximilian I. It is formed of black marble, supported on each side by statues of the dukes Albrecht V. and Wilhelm V.; while at each of the four corners there is the figure of a fully-harnessed knight resting on one knee. It was designed by Candido, whose works are highly estimated in Bavaria. St Michael's church, formerly a chapel of the Jesuits, and standing a short distance from the cathedral, was commenced in 1583, and belongs to the later Italian style of architecture. Its interior, however, presents but few objects of attraction, excepting Thorwaldsen's monument of the Duke of Leuchtenberg which exhibits great power of grouping. St Peter's, in the Rinder market, is the oldest church in Munich; it was built in 1370, and restored in 1607, having been injured by a stroke of lightning in that year. The churches of more recent date are,—St Ludwig's; All Saints'; St Boniface's, with a Benedictine monastery attached; and Mariahilf, in the suburb of Au. The first was commenced in 1829, and belongs to the Byzantine style; it is surmounted by two towers, each 208 feet high; and the length of the nave is 237 feet. All Saints' chapel is in the same style, but of smaller dimensions; while the Basilica of St Boniface is an imitation of St Paul's at Rome; it was commenced in 1835, and completed in 1850. Many admirable frescoes adorn the walls of these churches, from designs by Cornelius and Hess, and no expense has been spared in the carvings and statuary of the buildings. There are also a Protestant place of worship, a synagogue, and a Greek chapel.

But the largest edifice in Munich is the royal residence, comprising the old palace, flanked by the Koenigsbau and the Festsaalbau. The first was designed by Candido, and commenced at the end of the sixteenth century, but it is not remarkable for architectural beauty. The chapel attached, however, is very richly ornamented, and contains, among other relics, what is said to be the veritable hand

of John the Baptist. The old portion of the palace contains the treasury chambers, where the crowns of the realm are preserved, along with many valuable jewels, one of which, a blue diamond, weighs 36 carats. Flanking this building, and fronting the Max-Joseph Square, is the *Neuer Koenigsbau*, or New Palace, a fine massive building in imitation of the Pitti Palace in Florence. The floors of the apartments are inlaid with variegated woods, and the walls are covered with frescoes representing scenes from the *Niebelungen Lied*, the poems of Walter of Vogelweide, and other works. The *Festsaalbau*, or building devoted to court receptions, balls, &c., is even more gorgeously fitted up than the New Palace. Among other apartments, the "halls of the beauties," adapted for card-playing, displays great taste in arrangement, and contains portraits of a number of modern beauties by Stieler. The Charlemagne rooms, so named from the number of pictures therein representing the chief scenes in the life of that monarch, is on the west side of the great ball-room, which measures 123 feet in length, by 47½ in width, and is profusely decorated with reliefs and paintings in the Pompeian style. The palace is provided with a royal garden; while the court theatre is in close proximity, occupying a prominent position in the Max-Joseph Square, where the General Post-office likewise stands. The *Pinakothek*, or picture gallery, one of the most extensive in Germany, stands in an open place in the suburb of Max. Directly opposite is the *New Pinakothek*, and in an adjoining square is the *Glyptothek*, or sculpture gallery. These three buildings form together the centre-point of art in South Germany. Their collections have been brought together and maintained by the zealous care of the court. The Old *Pinakothek*, commenced in 1826 and finished in 1836, was designed by Klenze, and is a long building, with wings on either side. The paintings are arranged historically, and occupy different rooms. They belong chiefly to the German and Dutch schools; but there is also a large collection of pictures by Rubens, and a considerable assortment of the Italian, French, and Spanish schools. The New *Pinakothek*, a smaller edifice, was opened in 1853, and is devoted to paintings of the nineteenth century. But perhaps even more interesting than either of the foregoing is the *Glyptothek*, containing a most valuable collection of ancient statuary and reliefs, formed by the late King Ludwig. It is an elegant building, in the Ionic style, designed by Klenze, and opened in 1830. Various apartments are occupied with Egyptian, Etruscan, and Æginetan antiquities; also with the statues from the temple of Jupiter Panhellenius, which are deservedly famous. There are separate rooms for the statues of Apollo, Bacchus, and the sons of Niobe, besides others devoted to coloured sculpture and to Roman and modern works. For students of the fine arts few towns, indeed, present such advantages as Munich. Besides the great institutions above mentioned, there are many of less pretension, containing valuable collections of ancient coins, sculptures, paintings, &c. A polytechnic institution, an academy of painting with eleven professors, and schools of architecture and music, are likewise established here for the advancement of art. The Royal Library, a very fine new building in Ludwig's Strasse, contains the largest number of volumes in Germany. They are variously estimated from 400,000 to 800,000, with 22,000 MSS., among which are a copy of Demosthenes, written on cotton paper from Chios, and the oldest manuscripts of the *Niebelungen Lied*, which formerly belonged to a convent in the Grisons. The other most important institutions of Munich are as follows:—The university, transferred here from Landshut in 1826, having faculties of theology, law, political economy, medicine, and philosophy, attended by 1700 students, and possessing a library of 147,000 vols. and 5294 MSS.; a veterinary seminary, with 8 instructors; a female school

Munich.

Municipal
Corporation.

of midwifery; and a military academy, attended by 142 cadets; also a school for the deaf and dumb; a royal blind asylum, with 7 teachers and 66 inmates; and a seminary for lame children, having 3 teachers and 15 scholars. There is also a royal institution, open to the children of the nobility, who are brought up here at the royal bounty till they are old enough to enter the cadet school or the university; the inmates number 24, and the teachers 16. The Royal Academy of Munich, comprising the three departments of philology, natural philosophy, and history, is composed of about 320 members, and has two commissions connected with it for the advancement of natural science and technology in Bavaria. An observatory, a botanical garden, and several museums, are also here. The general prison is remarkably well conducted, on the principles of a reformatory more than of a gaol. The inmates are forced to work at their respective trades, and any profits that may arise thereon are paid over to them on leaving. Munich is ornamented with a fine park, called the English Garden, and also with many fine monuments, the most interesting of which is the bronze obelisk in Caroline Platz, raised to the memory of 30,000 Bavarians who were lost during the Russian campaign of 1812-13, in which they formed part of Napoleon's army.

The manufactures of the town are unimportant, and are mostly connected with science and the fine arts. They comprise philosophical instruments, paint-colours, lithographic stones, gold and silver lace, carriages, and cloth-stuffs, besides paper, oil, &c. There is a considerable trade in literature, and twelve newspapers are published in the town. Munich is connected by railway with France and North Germany, and will shortly have the same means of communication with Austria and Italy.

The history of Munich commences with the thirteenth century, when it was known as a walled town, whose arms or shield bore the representation of a monk. The Emperor Ludwig took up his residence in it in the beginning of the fourteenth century, and restored and enlarged it in 1327, after a destructive conflagration. It became the capital of Bavaria about the beginning of the next century, and for many years after increased slowly but steadily in importance. In 1632 the town was entered by Gustavus Adolphus, and its arsenal demolished; but with the exception of this event, its history has been one of undisturbed peace. The ultimate advancement of Munich, however, to the rank of a first-rate town was reserved for the reign of Ludwig I., at the commencement of the present century. This monarch, both when crown-prince and king, used his utmost efforts, by means of erecting new galleries of art, and building additional suburbs, to raise this town to the position of the Athens of Germany, and his endeavours have certainly to a great extent been crowned with success. The population of the town has increased more rapidly perhaps than any town on the Continent. Pop. of town and suburbs (1812) 40,638; (1846) 113,384; (1855) 132,112.

MUNICIPAL CORPORATION: MUNICIPALITY. The institutions so familiarly known throughout Christendom by these or similarly-derived names, owe their origin to the peculiar internal constitution of ancient Rome. Her citizens, self-relying and impatient of control, adjusted their method of internal government to republican and representative principles, while their haughty spirit of domination over the rest of the world led them to demand conformity among their dependents, and to stamp the character of their own peculiar institutions over the wide arena of their conquests. The protracted vitality which carried the municipal system, through the breaking up of the empire, to a resuscitation in amalgamation both with southern feudality and the Saxon institutions of Britain, forms one of the most curious and eventful features in the constitutional history of the modern European nations.

Municipal
Corporation.

One of the leading social contrasts between modern Europe and the ancient communities with whom we have acquaintance is, that the feudal system rendered the country equal, if not superior, to the towns; while in ancient nations all greatness, power, and wealth seem to have been concentrated in cities, as in Babylon, Nineveh, Tyre, and Carthage. If there were nomadic leaders of rank and mark, they bore scarcely a higher relative position towards the rulers and other great men dwelling in cities, than an Australian squatter might bear in the present day to the head of some great territorial house among the British aristocracy. Egypt seems to have possessed wealth and greatness beyond the walls of a predominant city; but, peculiar in its geographic character, as a narrow stripe of marvellously fertile land, it might be deemed one continuous city. In Greece, too, although a common spirit of nationality prevailed, and no central city exercised unrivalled control, yet the prevailing political power was in the cities. But to whatever extent the constitution in other ancient cities may have influenced that of Rome, they have had no direct effect on the creation of the municipalities of the middle ages and modern times, which naturally take whatever they have derived through the ancient world from that one great municipal corporation, which professed to govern all the nations of the earth.

The governing bodies in modern municipal corporations—the mayors, aldermen, bailies, common council, &c.—are the direct representatives of the *comitia curiata* and the senate of ancient Rome. It is of course in the form which it had developed in the later days of the empire that we must seek for the chosen models on which later municipalities were formed. The formation of the Roman constitution, as a separate and more extensive object of inquiry, goes back to far earlier periods; but the time when it was dispersed over multitudes of smaller communities as a form of provincial burgal government, corresponds with the establishment of the imperial authority over what is called the Roman world. Hence the subsidiary municipalities were modelled on Rome, not as a republic, but as an empire. The republican forms, however, subsisted after the empire had been long established, and were thus communicated to the municipalities. Cicero, in his second philippic against Anthony, desiring to describe the several elements of the Italian organization in their order, says, “*Horum flagitiorum iste vestigiis, omnia municipia, præfectura, colonias, totam denique Italiam, impressit.*”

After the two principal classes of municipal institutions, the *municipia* and the *colonia*, Savigny enumerates as inferior corporations *fora*, *conciliabula*, and *castella*,—all communities partaking more or less of the elements of the highest and most perfect municipal organization, the *municipium*. When the citizens elected their magistrates and made laws in Rome, they did the like in the municipalities; and when the power was transferred to the emperor and the senate in the imperial city, it fell into the hands of the *curia*, or council of decuriones, in the cities or municipalities, acting under the Roman governor of the province, who represented the emperor. The magistrates were chosen from the *curia*, as those of modern corporations are elected by the council; and a practice arose by which those leaving office presented their successors for adoption. The supreme elective magistrates in the municipalities—the representatives of the consulate in Rome—were termed *duumviri* or *quatuorviri*, according as their regulated number was two or four.

Such appears to have been the prevailing character of the *municipium*; but there were many varieties in the constitution of Roman cities, as there are in those of the present day. In some the elective rulers were called *quinquennales*, because they retained office for five years; while in others the magistrate virtually supreme was a censor or a *præfect* sent from Rome. In all in-

Municipal
Corporation.

stances, however, the electoral offices became a mere form after the consolidation of the empire; and when the prætor was superseded by the imperial advisers and judges in the capital, the imperial governors became supreme in the provinces. The very curia, or close council, which usurped the power of electing the magistrates, became, in the end, degraded by the uses to which it was made subservient by the imperial government. They were made responsible for the payment of the taxes; and from a supreme legislative and administrative body degenerated into the mere instruments which the imperial officers employed for carrying into effect the more disagreeable functions of government. Before the revival of municipalities the office had become a burden instead of an honour, and it was thrown, as a sign of contempt and oppression, on Jews, heretics, and other persons whom the government desired to mark with disrespect.

We know little on the very interesting point, how far the Roman municipal system existed in Britain. Two English towns are known to have had municipalities, York and Verulam; and it may be supposed that London, mentioned by Tacitus as a considerable place, had the rank of a municipality. There were several colonizæ and other sub-municipalities in Britain; and if the map of Richard of Cirencester can be believed, they penetrated as far northward as Inverness. Some English towns have retained through all intervening changes names which stamp their Roman origin, as Manchester, Winchester, and all those ending in *chester*. It is a natural supposition that a portion of the municipal constitution imparted to the more southern British towns by the Romans might have lived through the Saxon period. But archæologists have found no real evidence of such vestiges, and on this matter we have no better guide than mere conjecture.

How the continental municipalities lived through the troubles which attended the fall of the empire, so as to retain that vitality which enabled them to grow to a second maturity, is among the problems belonging to that epoch of confusion. In most instances the ancient municipal principle ruled or modified the administration of communities which had otherwise grown up. It is certain, however, that several cities of Italy, some in the south of France, and a few in Germany, such as Cologne, may be said at this day to be under the authority of a magistracy who date their origin from the Cæsars. Savigny and other writers have proved that the Roman law never died in Europe, to be raised from the grave by the discovery of the Pandects at the siege of Amalphi, according to the old popular belief. Through the strange confusion of nations, ever restless and transitory, an arrangement was adopted, as it were by common consent, that each tribe or people should, as far as consisted with the rights, or rather with the power of their neighbours, use their own laws. Thus the descendants of the Roman citizens, poor, obscure, and ever diminishing by absorption into other communities, kept up the more familiar and daily applicable principles of their own law; and when the world became settled, these, from their comprehensive and symmetrical character, gradually predominated, forcing out of use a more or less proportion of the original customs of the people in every country. The remnant of the Romans were essentially *cives*, or citizens. Their city was the state; and the term which they used to express attachment to the city has, in the words citizen, civism, citizenship, and the like, been used in France, and other countries which derive their language from Rome, to express attachment to one's country or state. But in the narrower acceptance of the term, the Romans were still citizens after the fall of their empire, since they were especially the dwellers in towns, while the conquering tribes occupied the open country. Hence, in a general way, we see how they preserved their own laws, and how those laws which affected the constitu-

Municipal
Corporation.

tion of the places in which they lived were the most sedulously tended. In Italy, besides Rome itself, several of the cities of Tuscany and Lombardy continued to possess municipalities, modelled after the imperial city, with consuls at their head, a senate, and occasionally a tribune. So vital was the municipal system among them, that in the days of Italy's mediæval prosperity they were sufficiently strong to constitute very powerful governments, aristocratically republican; and Europe, when she had become thoroughly feudalized in her notions, looked with astonishment at the atomism of mercantile or banking citizens, who not only vied with the highest feudal aristocracy, but were, as in the example of the Medici family, virtually royal houses. Nothing is more curious in the preservation of the Roman municipalities, than the method in which an equivalent to the broken authority of the empire was supplied to them from a totally different source. It is needless to remark, that the form of European history and institutions owes much to the fact, that while the civil power of the empire was destroyed, its ecclesiastical power, being attached to the destinies of Christianity, continued to exist, and even to take up many of the elements of the civil power as they dropped from time to time from the imperial grasp. The municipalities required leaders and directors, and the hierarchy of the church was at hand to lead and direct them. In Italy it came to be an almost constitutional rule, that the archbishop or bishop was the head of the leading town, smaller towns being headed by ecclesiastical persons of a lower grade. The system penetrated through part of France and of Germany. It did not reach England in its original purity, but became there mixed with the feudality which made a borough sometimes hold by tenure of an ecclesiastical dignitary. It is a matter of dispute by what original title the bishops sit in the House of Lords, and it has been said that they are a remnant of the old feudal baronage by tenure, sitting among the peers in right of the temporal lordships attached to their sees. But old as this origin is, the lordships which bishops may have held over city municipalities is of a still older date. We retain a relic of the municipal authority of the bishop in the notion of a city, which is stated in many legal books of reference to be a town in which there is a bishop's cathedral. The municipal bishop has almost disappeared from Europe, but the prototype of his civic authority still remains in the regal authority exercised by the bishop of Rome as a temporal prince.

Before feudality had come to its maturity, the towns had generally assumed their natural condition as communities governed by their own civic officers, the church betaking herself to things which were, or which she claimed to be, solely within her proper spiritual function. As the feudal system grew in strength, the municipal system, its natural rival and antidote, waxed powerful along with it. The two great types of the character of the age were the feudal lord's castle and the free or regal city,—both invested with characteristics unknown, at least in their fulness, to any previous social conditions of which we have an account. From those peculiarities in the condition of the European powers which divided the territories of the empire, so often discussed and so well known, the dominion over land and the dwellers in it became the great source of feudal eminence, suspending all the other elements of superiority,—such as great moveable wealth, the possession of many slaves, high office, or the privilege of taxation. The feudal lord lived in the country in his domains, and there built a fortress; which was not a place of strength to which an invaded people might retire for refuge, but an edifice of a new and totally different character,—a fortress overawing the surrounding country, a prison for the refractory, and a mansion for the feudal chief,—all in one. The peasantry and other feudal inferiors nestled round this place of strength

Municipal
Corpora-
tion.

for their own safety, and thus made a town which, while it continued small, was under the dominion of the lord, but sometimes became sufficiently large, wealthy, and powerful to assert its independence, and join the community of free cities which arose in rivalry of the chief and his stronghold. The aggressive spirit of feudalism, bringing all within its grasp as the dependents of some superior lord or other, left no room for separate independence. The *aremanni*, *allodials*, or other men of substance, who were neither lords nor vassals, found themselves crushed out, and naturally took refuge in the same sanctuaries where the remnants of the Roman population had found a congenial retreat—the municipalities. Various events tended to increase the strength and influence of these. The Crusades brought them trade, the object for which they were best suited, and at the same time weakened the hands of their rivals and oppressors. The revival of the study of the Roman law in the twelfth and thirteenth centuries was virtually the revival of the peculiar institutions which separated and protected them from feudalism. The Roman law had been promulgated in a despotism, yet it was peculiarly fitted to introduce elements of freedom to a state of society where feudalism was prevalent. It countenanced no distinctions in position among subjects; all under the emperor were equal, with the same rights and obligations, unless, indeed, it were the superiority conferred by citizenship, which yet did not confer power on one man over another. So much for freemen; on the other hand, the slaves were mere property or chattels. Feudality, however, was antagonistic to abstract slavery, having ever a tendency to the serfdom which attached the subordinate to a particular estate or a particular house, in reference to which the theory of the law, at least, gave him rights as well as obligations. The citizens could not well possess that power over their fellow-men which was denied to the feudal lord, and a pure republican freedom, of which the Roman law was an effective and suitable interpreter, prevailed in the cities.

Still the aggressive spirit of feudalism pressed hard on these communities. Except in the case of those which, like the great Italian cities, were powerful enough to be virtually states, in the European system, the towns generally found it necessary to come, in some shape or other, into the feudal hierarchy. If the citizens could not be made vassals individually, the community might acknowledge a superior in a collective capacity; and it became the interest of the towns in this manner to choose a protector. Still the hereditary principle, the several feudal exactions, and, above all, the subinfeudation which put a long hierarchy of masters over the humbler grade of vassals, was resolutely and, in many instances, effectually resisted. Laws still in full practice show vestiges of this long contest between the Roman and the feudal law. They are very distinctly seen in Scotland, where the owner of land or houses in a royal burgh is always a vassal, and can hold by no other tenure, but is a vassal of the crown only, no overlord having been able to intervene between the burgh and the sovereign. In all the surrounding territory there is a system of subinfeudation, by which the owner of land can sell it to another as his vassal, thus reserving, in the shape of the vassal's dues, a sort of perpetual rent called a feu-duty. But the owner of property in burgh tenure can only substitute a purchaser in his own place as a vassal of the crown.

This vassalage to the crown was indeed one of the great elements of strength which carried the municipalities of the middle ages through their difficulties and dangers. Arising from common causes, it had common effects over Europe. As some of the great lordships enlarged themselves into kingdoms, their reigning heads naturally felt that the most dangerous opponents of their rule were the feudal aristocracy, above whose position they had soared. They found on their territories municipal communities possessed of

some wealth and strength, whose interests and feelings were opposed to those of the aristocracy; and it was always among the temptations to which a monarch was subject in his hour of feebleness, to make common cause with these communities. When the feudal lord who held a municipality in vassalage was tired out in a long contest with the insurgent citizens, or when he was offered a considerable tribute, he came to terms with them, agreeing to allow them certain exemptions from feudal exaction. The document acknowledging these exemptions, when it became matter of uniform practice, was called a charter. But if such a treaty with a subject lord, whose observance of it could not perhaps be very implicitly trusted, were of any value, far more precious was that royal charter in which a monarch embodied the terms of his alliance, and his protection of the citizens against their oppressors. Thus the municipal corporations became an integral part of the feudal hierarchy,—a fact which, as we shall presently see, had an influence on the national constitution of the European kingdoms, separate from its influence on the constitution and condition of each separate municipality. Hence, when the system was at its prime, the municipalities or boroughs of Europe might be divided into three great classes: 1st. The free cities, which enjoyed such an independent municipal constitution as the Italian and other cities of the Roman world enjoyed before the encroachments of the empire—such as Florence, Venice, Genoa, Hamburg, Lübeck, and Novogorod. Some of these independent cities had been Roman municipalities which shook themselves free at the dissolution of the empire; others had arisen in feudality, and accomplished their freedom by war or purchase, or partly by both; but in all cases they were large, rich communities, capable of maintaining fleets or armies, and of holding a diplomatic character among the European powers. In a feudal hierarchy these held the position of sovereigns, sometimes exercising a very tyrannical sway over districts of which the people and their lords owned them as feudal superiors in the highest grade. It is almost needless to say that the power of the crown prevented such independent municipalities from arising in Britain. London, however, with peculiar privileges and powers, which even at the present day seem sometimes to bid defiance to the power of the legislature, approached very close to municipal independence and the establishment of a free city. The asserted right to exclude the royal troops from the precincts of the city, which possessed its own peculiar army, and the semi-sovereign rank and etiquette enjoyed by the lord mayor, seem to have been very incomprehensible to foreign writers, who have sometimes greatly exaggerated the actual privileges of the city. In the *Dictionnaire de Trévoux*, for instance, it is authoritatively laid down that the lord mayor is the principal *milord* of the realm, and in the case of a vacancy in the throne is, for the time being, governor of England. The second great class of municipalities were those which held royal charters, and were therefore, like the great lords, in the position of prime vassals of the crown. These in many instances had vassals under them, sometimes in the shape of small municipalities or corporations, sometimes in the shape of individual holders of feudal tenements more or less important. The chief cities in the United Kingdom were of this class; and wherever the crown was strong, it did not permit subject superiors to hold considerable towns in vassalage,—although frequently a neighbouring lord might exercise a very powerful influence in the councils of a royal municipality near his castle, and such a person was often propitiated by being invited or allowed to hold the highest office in the city, becoming its patron and to some extent its ruler. The lowest class of municipalities were those holding, not of sovereign princes, but of lords or subjects-superior, themselves bound to do homage to a sovereign. These were virtually the communities which, from

Municipal
Corpora-
tion.

Municipal
Corpora-
tion.

their smallness or poverty, had not been able to achieve their freedom, and are only to be considered as municipal corporations in name, from their being so ranked in the feudal hierarchy.

There were, of course, many minute distinctions and variations in the municipalities of the different European nations; but they will generally be found capable of classification into these leading divisions, since a remarkable uniformity pervades their constitution throughout Europe. This uniformity had its origin in the universal study of that Roman law from which the notion of municipalities was derived, and also, in some measure, from the uniformity of the feudal system itself. The necessary admission of the crown municipalities as an integral part of the feudal system, has been productive of signally important political consequences. It came thus to pass, that in the feudal assemblages which acquired more or less vitality in every country in Europe, and in Britain grew in strength until it became the imperial Parliament, the municipalities bore a part. Without them there would have been a gap in the feudal edifice. But all those who enjoyed the privileges of the municipality could not attend at the king's high court; the community must select certain citizens to pay suit and service as it elected its superior officers. Hence came the principle of representation, which made the House of Commons in Britain, and has repeatedly struggled into existence in France; arising fresh from the old municipal system, in the memorable instance of the meeting of the States-General, which began the first revolution.

It may now be appropriate to notice the leading peculiarities in the history and constitution of the municipalities of the United Kingdom. From the causes already noticed, the general uniformity pervading the municipal system extended even to England; but there were fundamental peculiarities in the real nature of the English municipal system which it has never lost. It has already been shown, that though it is not impossible that Roman municipalities may have lived in Britain through the Saxon invasion, no corporation has been actually traced among us to such an origin. The materials on which the corporation system was remodelled under the Norman kings, were evidently those institutions of the Saxons which divided the country into communities of tithings and hundreds, on the principle of common responsibility among the tithing men, and the duty of attendance at the hundred court. There are but faint contemporary traces of the constitution of the Anglo-Saxon towns; but their condition, as the Conqueror found them, may be gathered from Domesday Book, and is in a great measure reflected by the subsequent charters granted to them when they were incorporated by the Norman kings.¹ There is a difficulty in understanding the precise nature of the Saxon town; because it was not in its constitutional character any otherwise distinct from other parts of the country, than so far as a thickly-peopled must be distinct from a thinly-peopled place. There existed nothing in the form of a corporation, such as it afterwards became under the feudal system, mixed with the Roman law. The institution nearest to it in character was the body of traders, sometimes united together in a town, with the Saxon designation of a *guild*. It is possible to find other distinctions, both in name and reality, between the habits and institutions of the town's-people and the country-men. The term borough was in use, having found its way from expressing a pledge or surety, through some course which can be only hypothetically followed, to apply to a body of men associated together, and of course subject to the Saxon law

of mutual suretyship. The term alderman, so familiar in later days, does not appear to have been originally burghal, though it became so in the later periods of the Saxon monarchy, after having designated an officer who represented, and was next in rank, to the king, over a shire or some wider district. There came to be such distinctions between county and town as are represented by the shire-reeve or sheriff for the county, and the borough-reeve or port-reeve for the town, with the corresponding shire-gemote and borough-gemote, at which the freemen attended and gave their pledges. The term "freeman" has been well known in late municipal history, chiefly from the easy political virtue of the men who bore so honourable a title. Its origin among the Saxon communities was not associated with general freedom. It was used to distinguish the freemen from the *thralls* or slaves. There was indeed a greater analogy in social condition between our Saxon ancestors and the southern states of North America, with their republicanism and their slavery, than it is always agreeable to acknowledge.

Although in all such matters broad classifications are open to doubt and criticism, it seems to be a fair conclusion, that at the time of the Conquest, and during the reigns of the early Norman kings, the constituency of a burgh, those who voted in its great affairs and chose its officers, were the free male inhabitants,—that is, those who were not slaves. As freemen, they were in municipal matters equal among each other. The feudal usages of the Norman dynasty naturally broke in upon the abstract division into freemen and slaves, communicating to the latter the modified slavery of feudal vassalage. But the condition of free men still attached to the citizens, and came to be communicated as a valuable privilege, by birth, marriage, apprenticeship, or acceptance into the free body of citizens. The serfs of the feudal lords were thus often rescued and enfranchised, much to the annoyance of their masters. Among the corporation records of Hythe are the following entries in the year 1399:—"Thomas Goodeall came before the jurats in the common hall on the 10th day of October, and covenanted to give for his freedom 20d., and so he was received and sworn to bear fealty to our Lord the King and his successors, and to the commonalty and liberty of the Port of Hethe, and to render faithful account of his lots and scots as freemen there are wont.

"Be it remembered, that on the last day of the month of March, in the Common House, John Brandon covenanted to give for his freedom 6s. 8d., and he was sworn to bear fealty to the Lord the King and to the commonalty and liberty of the Port of Hethe: and to render faithful account of his lots and scots when they shall accrue, as persons are wont to do—and the said John Brandon is admitted."²

The obligation of "scot and lot," to which these men became liable on their admission to the franchise, is another familiar expression connected with municipal constituencies. It very expressively applied to those who participated in common in the taxation and services of the burgess. The word *scot* means a tax, coming from the same origin as *scutage*, and the Danish *skat*, a tax or tribute, a word still of practical use in the Orkney Isles. The *lot* means the obligation to perform the public services which might fall to them by due rotation. The freemen—burgesses, or whatever they may be termed—transacted their business by common council; and here we have the origin of another term familiar in modern municipal nomenclature. The *commune concilium* evidently referred to the collective decision in council of the burgesses—their vote, in short, after

tion.

¹ For an ample store of information derived from Domesday Book, the charters, Acts of Parliament, litigations, Parliamentary inquiries, and other sources of information on this head, reference may be made to the three large volumes of *The History of the Boroughs and Municipal Corporations of the United Kingdom*, by Mereweather and Stephens. The chief defect of this book is the large quantity of superfluous matter contained in it.

² Mereweather and Stephens's *History of Boroughs*, 746.

Municipal
Corpora-
tion.

consultation or debate. The term seems, by a metamorphosis which would be interesting if it could be traced, to have come at last to apply, not to the act of the burgesses in transacting their business, but to the select body who transacted it for them. It was not until after incorporation had for some time been in use that the management of the municipal affairs fell into the hands of a select council.

The early Norman kings granted charters to the towns. These did not grant them privileges, but secured to them those privileges and systems of internal organization which they had long been accustomed to. It cannot be said, as Guizot says of France, that the charters were gained by an insurrection and a war, and were in fact the terms of a treaty between the monarch and the insurgents. That act in the drama of the feudal history had passed over before the system in its maturity came over to Britain. But the charters were in some measure extorted from unwilling granters. It was contrary to the spirit of the feudal monarchy, that there should be within itself acting constitutions not owning the monarch as the author and regulator of their functions. The choice lay between the destruction of the privileges of the boroughs and a frank acknowledgment of them. The latter alternative was of necessity adopted. Many separate local reasons concurred in rendering the granting of charter after charter an act of politic discretion. Not the least of these was the facility of collecting the taxes. If the king appointed a bailiff to collect the revenue of a borough, his task was difficult and dangerous, if in the end successful; it therefore served the interest of both parties, that the citizens should agree to collect among each other, and remit the proper sum, on the condition of their being privileged from the intrusion of the royal bailiff. Sometimes the charters granted not only exemptions from vexatious interference, but special and exclusive privileges; and in the acquisition of these, London, from its predominating influence, was from the first conspicuous. Thus the Conqueror himself, in what may be called the earliest charter of the city, says with emphatic brevity,—“William the King friendly salutes William the Bishop, and Godfrey the Portreeve, and all the Burgesses within London, French and English. And I declare that I grant you to be all law-worthy as you were in the days of King Edward, and I grant that every child shall be his father's heir after his father's days: and I will not suffer any person to do you wrong. God preserve you!” (Mereweather and Stephens, 287.) The terms of peace thus hastily communicated were matured into the charter of Henry I., which, among other things, concedes, “that the citizens might place whom they would of themselves to be sheriff, and also one to be justiciary for keeping the pleas of the crown; that none other should be justiciary over the same men of London; that the citizens should not plead within the walls for any plea; that they should be free from scot and lot, danegelt, and of murder, and none of them should wage battel. If any of the citizens should be impleaded concerning the pleas of the crown, the man of London should discharge himself by his oath to be adjudged within the city. No one was to have lodging assigned him within the walls: nor any one of the King's household, nor of any other, have lodging assigned to him by force. That all men of London should be quit and free with their goods throughout England and the ports of the sea, of toll passage, lastage, and all other customs.”¹

In the royal charter we have the foreign municipal system, consisting as it did of a mixture of the old Roman municipalities and of feudality, brought over and superinduced on the Saxon burgal communities. This could not happen without the introduction of the Roman law, cordially as it was hated by the common lawyers. It made a unifor-

mity in appearance between the English and the continental municipality, but the fundamental principles of the old Saxon system still directed the spirit of the English borough. There was, however, a further change at hand. The early charters were not charters of *incorporation*. The corporation, indeed, was an ingenious result of the joint labours of the civilians and common lawyers. The law books speak of all the boroughs as having been corporations from the beginning; and great caution is necessary in referring even to printed records and acts of Parliament on this point, because the later copyist or editor, saturated with the legal phraseology of his own age, would insert the word “corporate” beside the word “town,” as if its omission in the original had been a mere clerical oversight. Among many other such instances, the title of the act 6th Rich. II., stat. i., chap. 9, in the ordinary printed editions of the statutes is, “that no victualler shall execute a judicial place in a city or town *corporate*,” while the qualification of being “corporate” does not occur in the body of the act itself. Perhaps the earliest known record of an incorporation dates in the year 1412, when the citizens of Plymouth “state that their town is a great port and resort for ships coming there, and that oftentimes it had been destroyed by the king's enemies, because it had not been enclosed between any walls or defensible fortress to resist the enemy: and pray that His Majesty would grant to them, their heirs and successors, inhabitants and residents within the same town, power annually to elect a mayor for the good governance of the same town: and that they, their heirs and successors, may be a body corporate to purchase free tenements for term of life or in fee without the King's royal license.”² In such charters as this, the citizens at large were to be incorporated; but subsequent incorporations narrowed the sphere of the corporate basis, for the purpose of including only that small body of official persons by whom the complex and artificial character of an English corporation could be kept up. There had been ecclesiastical corporations of an earlier date, and the corporation was thus in fact a mechanism calculated for ecclesiastical rather than for civil purposes. A few considerations will render obvious how it gradually modified, and in the end totally changed, the constitution of the English boroughs. In the first place, the charter itself gave to the office-bearers of the municipality an authority from above, competing with their authority from below, as the elected of the freemen. The power of this sanction was strengthened by the incorporation, because the persons incorporated were in reality the officers, not the citizens. There is a tendency in all elected bodies to strengthen their position and become independent of their constituencies; and the royal charter giving certain privileges and functions to the elected, with that perpetual succession and uninterrupted vitality which are the boasted merits of the English corporation, naturally aided the office-bearers in the assertion of a power independent of the community. But it was the nature of a charter of incorporation not merely to acknowledge but to confer privileges, and their extent and character were dictated by the royal authority which conferred them. The difference between such a process and the mere confirmation of established privileges is obvious. If the rights and privileges of the freemen or burgesses in any ancient city were confirmed by the crown, their character had been originally adjusted by these freemen or burgesses themselves, and in their own way. When the crown absolutely conferred the privilege, the crown could impose conditions on it, and could, in particular, limit the class who were to enjoy it. Thus, after the system of incorporation came to its maturity, the municipal corporations fell into the hands of bodies of men more or less restricted, who

Municipal
Corpora-
tion.

² *Ibid.*

Municipal
Corporation.

could admit or reject applicants for freedom or citizenship, could lay down factious or capricious regulations for the franchise, or in many other ways impart the character of their own opinions or interests to the community. At the same time, what could be conferred by the absolute will of the crown was liable to be revoked. The law said, that if a municipal corporation was false to the tenor of its charter, that charter should be annulled; and as it had come to be a fiction of law, that every municipal privilege and power must be founded on charter, though none could be produced, the whole municipal system was at the mercy of the courts of law at a time when these were under the influence of the crown. Hence came those proceedings by writ of *quo warranto*, for stripping their privileges from municipalities acting independently, which preceded, and in a great measure caused, the revolution. That event did not put an end to charters of incorporation or improve their character, though, of course, no attempt has since been made to attack and demolish in a body the corporations acting offensively towards the ruling interest. During the reign of William III., and subsequently, the influence of the crown in creating municipal corporations, and adjusting them to the objects of the ministry in power, was profusely employed, and became too conspicuously connected with British history and politics to require commemoration here.

Soon after the era of the Norman conquest we find traces of a municipal system in Scotland closely resembling that of England. From the time of Malcolm IV. downwards, charters were profusely granted; but although they were named charters of erection, and are supposed to have created the municipalities to which they refer, yet they generally contain internal evidence that the communities acknowledged by them enjoyed an earlier existence. In muniments of the reign of David I., chiefly relating to ecclesiastical houses, there are references to towns which are the king's own or royal burghs (e.g., *Burgum meum de Haddington*). A capitulary of laws of considerable antiquity is called the Laws of the Four Burghs (*Leges Quatuor Burgorum*). If the collection as a whole be perhaps no older than the fourteenth century, it is supposed that some of the laws themselves may belong to a far more distant date. The four burghs to which it applied were Edinburgh, Stirling, Berwick, and Roxburgh. It is remarkable that several of these laws refer to foreign commerce and the loading and unloading of vessels; and could thus have scarcely applied to any of the four burghs except Berwick. These four burghs formed an important court, of the authority of which there is a curious testimony in the year 1292, when a great part of Scotland was in the hands of Edward I. A question of private right, which came before a Parliament held by Edward in Newcastle, was referred to the court of the four burghs, as expositors of Scottish municipal customs. The similarity of these laws to many of the charters of the English burghs is a striking evidence of the similarity of the municipal customs of the two kingdoms. Many portions of the charter of Newcastle are identical with the laws of the four burghs; and these bear evident marks of a unity of customs and laws, even when compared with the earliest charters of London. As in England, there is no trace of the corporation proper in the early Scottish municipalities. To be a free inhabitant, watching and warding, and paying the imperial dues, was to be a burgess, with the elective rights and other privileges of a burgess; and there was no higher grade but that which was conferred by office. In some instances the possibility of incorporation is negatived, by the charter being granted to all the burgesses spread over a district of country. One charter of William the Lion confers privileges on all burghs in Moravia or Moray; another confers *liberum ansam* (the right of trading,

Municipal
Corporation.

a term having the same origin as the name of the Hanse towns) on all the burgesses north of the Mount, or of the Grampian chain. The system of free election without a corporation, which separate documents show to have belonged to the English boroughs, is distinctly embodied in the burgh laws of Scotland. The whole election code is translated as follows in a Scottish version, probably of the fifteenth century, of which it is necessary slightly to modify the spelling:—"At the first mune next efter the feast of Sanct Michael, the Aldermen and the Baillies sall be chosen thruch the counsale of the gud men of the toune, the whilk awe to be lele and of gud fame, and they sall swear fewte to the Lord the King, and to the burges of the toune, and they sall swear to keep the customs of the toune, and they sall not hald laugh [hold law] on any man or woman for wroth na for hatred na for dread or for lufe of ony man, but through ordinance counsel and dome of good men of the toun. Alsua they sall swear that neither for rudness na for lufe na for hatred na for cosynage na for tinsel of their silver—they sall nocht spare to do right to all men." In this succinct little code it will be observed that there occurs the same expression, the *counsale*, and in the Latin original the *commune concilium*, which became so curiously perverted in England.

The analogy between the Scottish and the English municipalities remained until the war of independence separated the two nations as hostile kingdoms. During the Saxon dynasty there was no more national division between the north of England and lowland Scotland, than between one province of Saxon England and another; nor was this community of nationality entirely severed even by the Norman conquest of England. After the war of independence however, Scotland, alienated from England, allied herself to England's greatest enemy, France, and the Scottish institutions became more or less tinged by the influence of the alliance. In the early municipal documents we find reference to the mayor, the aldermen, and the coroner, as in England. But afterwards the chief magistrate became the provost, or prevost; the inferior magistrates were bailies; the head of the craftsmen and of the merchant guild became the deacon, dean, or doyen. The towns, as every traveller in Scotland knows, were built after the French fashion; and in their records the streets are sometimes called "rues," a word which, by a natural transition, was corrupted into rows.

The example of France, which had probably given encouragement to the narrowing of the municipal franchise in England, was boldly embodied in an act of Parliament in Scotland. In the year 1469 it was enacted, touching the election of officers in burghs,—“Because of great trouble and contension yearly for the chusing of the same through multitudes and clamour of commons, simple persons, it is thought expedient that nane officers na council be continued after the King's laws of burrows further than a year, and that the chusing of the new officers be in this wise—that is to say, that the auld council of the toun shall chuse the new council in such number as accords to the toun; and the new council and the auld of the year before shall chuse all officers pertaining to the toun.” This deliberate system of self-election, after meeting with some resistance at first, was the general rule followed, with local modifications and peculiarities, throughout Scotland down to the year 1833.

Long before this period the municipal system had come under deep discredit. In England the charges against it were, political corruption; general waste and extravagance; the mismanagement, misdirection, or appropriation of the property devoted to public purposes; and a general abuse of the powers and privileges of municipal offices for party

¹ See the passages compared side by side in the preface to the Record edition of the *Scots Acts*, p. 33.

Municipal
Corporation.

or personal ends. In all parts of the empire it was remarked that, instead of being places of refuge for oppressed liberty, the corporations were frequently centres of oppression and extortion,—those privileges and immunities which were conferred on them for protection against feudal and regal power, being converted into personal monopolies and privileges, which invidiously excluded the public at large, to the detriment of the national welfare. In England the exclusive trading privileges asserted by the corporations were from an early time checked and modified by acts of Parliament. In Scotland monopolies were held and rigidly enforced down to the pursuits of the humblest craftsman. In the *Book of Advice*, written by King James for his son, there occur the following unexpectedly sagacious remarks on this subject:—"The craftsmen think we should be content with their work how bad and dear soever it be, and if they in anything be controlled—up with the blue blanket. But for their part, take example of England, how it hath flourished in wealth and policy since the stranger craftsmen came in among them."

The Scottish system, which was admitted to be far more exclusive than the English, was reformed in the year 1833; but the exclusive privileges of trade were not abolished until 1839. In England a general act "for the regulation of municipal corporations," abolishing trading privileges, and providing for vested rights connected with the freeman system, passed in 1835. The English municipal franchise is in the resident householders; the Scottish in the ten-pound parliamentary voters. The Irish municipal system, which was not indigenous, but a mere artificial imitation of the English, exhibiting many of its vices, but none of its virtues, was not reconstructed until the year 1840.

The demand for municipal reform was the companion of the demand for parliamentary reform. It was often said, that could the old municipal system be restored, it would be a rallying-point for the protection of free principles against a corrupt Parliament. Both the reforms were conceded at the same time; and the result has been to place reformed municipalities in an unfavourable contrast with a reformed Parliament. There is no doubt that, had the municipal improvement been achieved earlier and alone, its importance would have been more keenly felt. At present the high public spirit represented in the House of Commons, and the stringent responsibility which that body is enabled to exact in all quarters where power is exercised, supersede other popular safeguards; and it is often thought that the public languidness towards municipal representation and responsibility, is apt to leave such power as local corporations possess, at the absolute disposal of any clever citizens whose activity or ambition prompts them to conduct public business.

In most parts of the Continent, those municipalities which were not strong enough to exist as independent governments fell before the aggrandizing progress of their sovereignties. In France, in one shape or other, the royal authority had by degrees displaced all the substantial powers of the municipalities. In the great towns there was still the *maire*, presumed to be the elective head of the municipality, with a body of *adjoints*, *assesseurs*, and *conseillers*, selected from the chief inhabitants. But in great cities the *maire*, who was the agent of the central government, as well as the head of the municipality, came to be chosen by the crown. In garrison towns the governor or his lieutenant was supreme; and in others the intendant of the province had a supreme authority over all civic bodies. At the first revolution the municipalities, such as they had become, were swept away. In the re-distribution of the country in 1791 into departments, cantons, and communes, the smaller towns were amalgamated with their communes; but the towns containing 5000 or more inhabitants obtained a separate municipality under the new system. Under Napoleon all the local electorates of any importance were super-

seded by the intervention of the *chef de l'état*. Under the government of Louis Philippe the king had the nomination of *maires* and *adjoints* in the communes which had 3000 inhabitants or upwards; and the royal influence was indirectly exercised by giving the appointment in the inferior communes to the *préfet*. This arrangement, shaken by the revolution of 1848, was re-adopted under the second empire as convenient and suitable to the policy of the imperial system. From the first revolution downwards, the word *municipal*, like many others in familiar use in ancient France, has practically dropped out of the constitutional nomenclature of the country. (J. H. B.)

MUNSTER, the most southern of the four provinces of Ireland, bounded on the N. by Connaught, on the E. by Leinster, and on the S. and W. by the Atlantic Ocean. It measures 150 miles in its greatest length, from Brow-Head, the most southern point of Ireland, to Meelick, the northern extremity of Tipperary; and about the same breadth in an eastern and western direction, from Dunmore Head in Kerry to Waterford harbour; extending over a superficies of 6,064,579 acres, of which 3,874,613 are arable, 1,893,477 uncultivated, 130,415 in plantations, 14,693 occupied by towns and villages, and 151,381 are under water. Of the uncultivated land, 634,000 acres are coarse pasture over 800 feet above the sea, and 1,259,000 under that level, including flow-bogs, &c. It has been estimated that 390,000 acres are improvable for cultivation, 630,000 improvable for pasture, and that the remaining 873,000 are incapable of improvement.

The ancient name of the province was *Mumhan* (in Latin, *Momonian*.) According to the older geographers, its maritime regions were peopled, commencing eastwardly, by the Brigantes, the Velabori, the Ibernii, the Lucenii, the Vodii, and the Cangani; whilst its interior was occupied by the Scoti. At a later period it contained the eight following principalities:—1. Hy Breoghan, now the county of Waterford; 2. Osragii, afterwards Ossory, and now forming parts of the Queen's County and of Tipperary; 3. Oir-Mumhan, East Munster, now Ormond, comprehending the baronies of Ormond and of Owney and Arra in Tipperary; 4. Tuath-Mumhan, Thomond, or North Munster, now the county of Clare; 5. Aine-Cliach, or Eoganach Aine-Cliach, now Limerick; 6. Ciar or Cerrigia, now Kerry; 7. Aoibh-Liathain, containing the northern part of the county of Cork; and, 8. Corcaluighe, the southern part of the same county, and the ancient kingdom of Cork. The principal toparchs or heads of septs in those divisions, several of whom assumed the title of King, but acknowledged the supremacy of the King of Munster, were the O'Briens, the Barrys, the M'Arthys, and the O'Sullivans. After the arrival of the English the greater part of the province became the property of the Butlers, and of different branches of the Fitzgerald family; amongst the latter of whom the Earl of Desmond long ruled the whole of its southern portion with an authority almost independent of that of the English crown. The old Irish proprietors were dispossessed, and the Anglo-Normans extended their feudal tenures to Ireland; the ancient Irish inhabitants becoming the occupying tenants of the confiscated land. On the death of the last Earl of Desmond, and the subsequent confiscation of his immense estates by Elizabeth, in consequence of his rebellion, the greatest part was again parcelled out amongst English adventurers, amongst whom were the celebrated Sir Walter Raleigh and Spenser the poet. The province is now divided into the six counties of Clare (formerly included in Connaught), Cork, Kerry, Limerick, Tipperary, and Waterford.

According to the ecclesiastical arrangements of Ireland, Munster formerly constituted the province of Cashel, consisting of the archbishopric of the same name, with which were united the diocese of Emly; the bishopric of Limerick, Ardfer, and Aghadoe; the bishopric of Waterford and

Munster.

Munster. Lismore; the bishopric of Cork and Ross; the bishopric of Cloyne; and the bishopric of Killaloe and Kilfenora. This arrangement was altered by the Church Temporalities Act, 3d and 4th William IV., cap. 37, which reduced the archbishopric of Cashel to the rank of a bishopric, subordinate to the archiepiscopal see of Dublin, and consolidated the whole province into four dioceses, in the following manner:—Cashel, with Emly, Waterford, and Lismore; Cloyne, with Cork and Ross; Killaloe, with Kilfenora, and also the sees of Clonfert and Kilmacduagh (hitherto forming part of the archiepiscopal province of Tuam); and Limerick, with Ardfert and Aghadoe, as hitherto.

The northern parts of Munster are, generally speaking, level. Towards the S. and S.W. the land rises into elevations of considerable height, Macgillicuddy's Reeks, in Kerry, being the highest mountain range in Ireland. Carantuo Hill, the most elevated of its peaks, is 3414 feet above the level of the sea. The mountains in the county of Cork stretch in the direction of E. and W., and the lofty range of Slieve-Bloom forms the eastern boundary of the province. The River Shannon passes through its northern part, separating the county of Clare from those of Tipperary, Limerick, and Kerry. The Suir, Blackwater, Lee, and Bandon water the southern districts. The only lakes of note are those of Killarney in Kerry, which owe their celebrity more to the picturesque beauty of their scenery than to the extent of their surface. The bays, creeks, headlands, and islands, which are numerous, and in most instances worthy of special notice, have been already mentioned in the general description of the island. (See IRELAND.)

The climate, though moist from its exposure to the prevailing south-western winds, which pass over it loaded with the humid exhalations of the Atlantic, is peculiarly mild. The severity of winter is but slightly felt even in its more elevated regions; whilst in its more level parts, along its southern shores, the unsheltered myrtle blooms richly, and the *Arbutus unedo*, indigenous in Kerry, attains an unusual size.

The soil throughout the level parts is peculiarly fertile, producing abundantly rich crops of every kind of grain, and many species of fruits which in other parts of the island are capable of being ripened only by means of an artificial atmosphere. The tract of land stretching across the counties of Limerick and Tipperary, from Askeaton to the limits of Kilkenny, has long been distinguished by the name of the Golden Vale, an appellation justly bestowed upon it from its singular fertility.

The extent of land under each description of crop in 1856 and 1857 was—

	1856. Acres.	1857. Acres.
Wheat.....	179,982	199,779
Oats.....	373,385	351,904
Barley, bere, rye, beans, and peas..	70,918	76,378
Potatoes.....	287,219	309,447
Turnips.....	121,207	114,983
Other green crops.....	28,032	30,745
Flax.....	3,575	2,883
Meadow and clover.....	384,097	404,686
Total.....	1,448,415	1,490,805

The total quantity of live stock in the province in the same years was—

	1856.	1857.
Horses.....	145,850	152,566
Cattle.....	1,073,625	1,084,256
Sheep.....	993,082	892,217
Pigs.....	343,176	427,340

As to its geological relations, the northern parts of Munster are included within the limits of the great plain of carboniferous limestone which constitutes the central formation of Ireland. The southern parts are mostly of the sandstone and carboniferous formation; the former being more

developed in the mountains, the latter in the more level parts. Bog is abundant and very generally distributed, although the province lies without the great central band, which embraces most of the soil of this description. Coal is found in the interior. There are two fields of this mineral,—one in Tipperary, where a branch of the great Leinster coal-field stretches into the province; the other, peculiarly termed the Munster coal-field, is of great extent, occurring in several portions of the counties of Clare, Cork, Limerick, and Kerry. The contortions of the strata, however, cause irregularity and uncertainty in the workings, and the district has not yet been sufficiently examined to ascertain the economical value of this great development of the coal strata in Ireland. The most extensive collieries hitherto worked are in the barony of Duhal-low, in the county of Cork. In both places the mineral is of the non-flaming or anthracite species. Several mines of copper, lead, and iron were worked with profit until stopped by the failure of timber for fuel, notwithstanding which a few are still carried on successfully. Mineral springs are numerous; that of Mallow, which is of the same nature with the hot wells near Bristol, maintaining a high character for its medical efficacy.

The population of Munster in 1821 was 1,935,612 souls; in 1831, 2,227,152; in 1841, 2,396,161; and in 1851, 1,857,412. The peasantry are a large, athletic, and handsome race, exhibiting in their oval faces and dark hair strong traces of similarity with the Spaniards. Their occupation is chiefly agricultural. The raising of grain, and the pasturage of cattle, which are exported in great numbers from Cork, Limerick, and Waterford, form their chief employment. The manufacture of frizes and coarse woollens, as also of coarse linen cloth for domestic consumption, is still carried on; and formerly the country round Carrick-on-Suir was the seat of an extensive woollen trade.

The province contains several of the largest cities in Ireland: Cork, with a population in 1851 of 65,745; Limerick, with 53,448; and Waterford, with 25,297 inhabitants. (H. S.—R.)

MÜNSTER, a town of Prussia, capital of the government of the same name and of the province of Westphalia, is situated on the Aa, a tributary of the Ems, 78 miles N.N.E. of Cologne. It is well but irregularly built, and has an air of great antiquity, the principal streets being lined with arcades, on which the upper storeys of the houses are supported. It was formerly surrounded by fortifications, but these have been destroyed, and their place is occupied by public walks, beautifully shaded with trees. The cathedral, begun in the thirteenth century, is a Gothic building with two transepts and two pyramidal spires. The oldest church in Münster is that of St Leger, built in the twelfth century, but its tower is in the later Gothic style of the fifteenth century. The church of St Lambert, also in the Gothic style, is a very fine building, and on its spire may still be seen the iron cages in which John of Leyden and the other Anabaptist leaders were exposed before their execution. Besides these, the town contains numerous other churches. The town-house of Münster is remarkable for its beautiful Gothic front, and contains in the interior the hall in which the peace of Westphalia was signed in 1648. Here are to be seen portraits of the ambassadors who then met, and also the seats and cushions on which they sat. The castle, which was formerly the residence of the bishops, is now occupied by the commandant. It is a handsome building; and the ground behind it, formerly occupied by the citadel, is now used as a botanical garden belonging to the Academy. Münster was formerly the seat of a university, but this was closed on the foundation of that of Bonn; and all that remains of it now is an academy, containing theological and philosophical faculties, besides a medical school and clinical institute. There are also a deaf-and-dumb

Munster.

Munster
||
Muntzer.

institution, two normal seminaries, a grammar school, art union, school of design, and two scientific institutions. The town has also an orphan asylum, several hospitals, and other charitable institutions. Münster is the see of a bishop, and is the seat of the highest law court in the province of Westphalia. The manufactures consist of woollen, cotton, and linen goods, starch, tobacco, sugar, &c.; and there is a considerable trade in these articles and in Westphalian hams, wine, &c. There is a canal between this town and the Ems; and it is connected by railway with the principal towns in the vicinity. Münster was for a thousand years (802–1803) an independent see, governed by its own archbishops, who were in many instances remarkable for their warlike achievements. The most important event in its history was its occupation in 1535–6 by the Anabaptists under John of Leyden; after which it was recovered by the archbishop, and the ringleaders were executed. Pop. 24,664.

The government of Münster forms the north-western part of the province of Westphalia, and is bounded on the N. by Hanover, E. by the government of Minden, S. by those of Arnberg and Dusseldorf, and W. by Holland; area 2432 square miles. The surface is generally flat, except a small portion towards the N.E., and it consists partly of cultivated ground and partly of sandy and heathy tracts. Iron and coal are obtained here in considerable abundance; but the soil is in general not very fertile, and the produce not more than enough for domestic use. Flax and hemp are the principal crops raised. The pastures are large and good, and great numbers of live stock are reared in this government. Linen is the chief article of manufacture; but iron, leather, cotton, silks, &c., are also produced. The government is divided into ten circles, and has a population of 421,935.

MÜNSTER, SEBASTIAN, one of the most learned scholars of his day, was born at Ingelheim in 1489. At the age of sixteen he repaired to Tübingen to sit at the feet of Reuchlin and Stöffler. There his passion for study induced him to seek the quiet of a Franciscan convent. But becoming in course of time a convert to the opinions of Luther, he threw off his monastic habit, and was appointed professor of Hebrew at Basle in 1529. His days and nights were now devoted to study, and several elaborate treatises on geography, mathematics, and philology proceeded from his pen. At length the robust constitution which had carried him through so many severe labours was smitten by the plague, and he died in May 1552. The most important of Münster's works are the following:—An edition of the *Biblia Hebraica*, in 2 vols. fol., Basle, 1534–5 and 1546; *Grammatica Chaldaica*, 4to, Basle, 1527; *Dictionarium Chaldaicum*, 4to, Basle, 1527; *Dictionarium Trilingue, in quo Latinis Vocabulis, Græca et Hebraica respondent*, fol., Basle, 1530; *Horologographia*, 4to, Basle, 1531; *Organum Uranicum*, fol., Basle, 1536; *Cosmographia Universalis*, fol., Basle, 1544; and *Rudimenta Mathematica*, fol., Basle, 1551.

MÜNSTERBERG, a town of Prussia, capital of a circle of the same name, in the province of Silesia and government of Breslau, is situated on the Oklau, 37 miles S. of Breslau. It is walled, but not very well built; and contains several churches, a synagogue, an hospital, and several courts of law. It has breweries, distilleries, tobacco manufactories, dye-works, &c. Pop. 4500.

MUNTZER, MUNZER, or MUNCER, THOMAS, an insurrectionary leader of the German Anabaptists, was born at Zwickau about the end of the fifteenth century. He was a priest, first at his native town, and afterwards at Altstadt, and he was at one time a follower of Luther. But at length his tenets assumed a fanatical tone, and his hot-headed zeal drove him forth to be the apostle of a revolution. Traveling into Thuringia and Suabia, he preached the abolition of

all legal penalties and all distinctions of rank, the establishment of a community of goods, and the speedy coming of Christ to set up the New Jerusalem. Such startling doctrines, falling among a population already excited with discontent against their rulers, hurried the ignorant peasantry into open revolt. A force of 8000 Thuringians rallied round Muntzer, and acknowledged him as their prophet and leader. He fixed his head-quarters at Mühlhausen. Thither the neighbouring princes, headed by the landgrave of Hesse, advanced to attack him. Terms of capitulation were offered to him in vain. He animated his troops by assuring them that a miracle from heaven would foil and confound their foes. A battle ensued, which ended in the complete rout of the insurgents. Muntzer was soon afterwards caught lurking at Frankenhausen. He was carried back to Mühlhausen, and beheaded in 1625.

MURAL CIRCLE, a principal fixed instrument in all the great public observatories, is generally of large dimensions, and is attached to a stone wall, or pier of solid masonry, placed in the meridian. It is employed to measure the zenith distances of stars. Tycho Brahe was the first who used the mural arc in his observations; and Flamsteed erected the first one at Greenwich in 1689. Mural arcs and quadrants were superseded at that observatory by the mural circle of Troughton in 1812, an instrument of much greater accuracy, and much less liable to derangement. (See ASTRONOMY, part iv., chap. iv., § 5.)

MURAT, JOACHIM, a distinguished French general whom Napoleon created King of Naples, was born on the 25th of March 1771 at La Bastide, near Cahors, where his father was an innkeeper. He acquired some slight degree of elementary instruction at a school in Toulouse, but his taste for dissipation and adventure soon drew him away from his studies. Having returned to the hostelry of his father, he engaged in the service of the house along with the domestics, and then enlisted in the chasseurs of the Ardennes, from which he soon afterwards either deserted or was dismissed. Having gone to Paris, he fell into such distress that he was obliged to serve at the table of a restaurateur. Being remarked for his activity and bearing, and his father having resolved to send him some assistance, he was admitted into the constitutional guard of Louis XVI.; and, on the disbanding of that body, which followed soon after its formation, he obtained a sub-lieutenancy in a regiment of chasseurs. Here he showed himself a furious revolutionist, and in consequence obtained rapid promotion. He was already lieutenant-colonel, and one of the most fervent adherents of Marat, when, upon the death of that ferocious tribune of the people, he wrote from Abbeville, where he was then in garrison, requesting the Society of the Jacobins at Paris to grant him permission to change his name into that of Marat. It is not known whether his request was positively complied with; but it is certain that, after the fall of Robespierre, he was, like Bonaparte, dismissed as a terrorist. Being restored to his rank at the epoch of the 5th October 1795, he served under the orders of Bonaparte, when the latter was employed to disperse the Parisians who had armed against the Convention. Attaching himself more and more to this young general, Murat showed much intelligence and bravery at the opening of the campaign of Italy in 1796, and became the confidential aide-de-camp of Bonaparte. During all that campaign, and the subsequent one of 1797, he greatly signalized himself by his bravery and success. In March 1798 he proceeded at the head of a column to the confines of the Valteline, and united that province to the new Cisalpine republic. He likewise preceded Bonaparte when, after the peace of Campo Formio, that general traversed Switzerland and Alsace on his way to Rastadt. Being sent to Rome with Berthier, he marched against the insurgents of Marino,

Murat.

Murat. Albano, and Castello, killed a great many of them, and caused to be arrested a considerable number of monks and prelates, reputed enemies of France. When the expedition to Egypt had been resolved on, he declared he would follow Napoleon through the world; and throughout the whole course of that expedition he distinguished himself, particularly at Mount Tabor, where, by a series of brilliant charges, he completed the dispersion of the Turkish army, and was rewarded with the rank of general of division. On his return to France with Napoleon, Murat rendered him effectual service at St Cloud, when he changed the form of the government and took possession of power. It was Murat who, at the head of sixty grenadiers, dispersed the Council of Five Hundred. He was immediately named commandant of the consular guard, and henceforth enjoyed unlimited favour. To draw still closer the ties which united them, Napoleon gave Murat his sister Caroline in marriage. He also employed him as one of his lieutenants in the army of reserve, and in this capacity Murat entered Milan, occupied Piacenza, and commanded the cavalry at the battle of Marengo. In the following year he commanded the army of observation, and governed, with the title of general, the Cisalpine republic. On the 1st of January 1804, he was appointed governor of Paris, with the rank of general-in-chief, and directed the military force when Napoleon was proclaimed emperor. A few days after this event he was elevated to the rank of marshal of the empire, and in the following year he was raised to the dignity of prince and of high admiral.

On the breaking out of hostilities with Austria in 1806, he passed the Rhine, pursued vigorously the Austrian corps under the Archduke Ferdinand, overcame the corps of Werneck, and entered Vienna on the 11th of November. He then marched against the Russians, and contributed to the victory of Austerlitz. Being invested with the grand-duchy of Berg, he assumed the style of a sovereign; figured in the two subsequent campaigns, particularly at the battle of Jena; made his public entry into Warsaw on the 28th of November 1807; and commanded the cavalry at the battle of Eylau, and also at that of Friedland.

In April 1808 he entered Spain at the head of a numerous army, and imprudently provoked an insurrection in the capital, which spread the flame of discontent throughout the whole of Spain. Being recalled from Spain, he was, on the 1st of August 1808, proclaimed King of the Two Sicilies, under the name of Joachim-Napoleon. As he succeeded Joseph Bonaparte, whom the Neapolitans despised, the comparison was to his advantage; whilst by the pomp he displayed, and his martial air and bearing, the *beau Sabreur* readily won the favour of the people. The invasion of Russia in 1812 recalled him under the banners of his former master. Being placed at the head of the cavalry, he took part in all the operations which preceded the capture of Moscow; he also commanded a separate corps at Kaluga, where at first he obtained some advantages, but subsequently experienced great reverses; and after the departure of Napoleon from the army, he was intrusted with the command of it in its disastrous retreat from Smorgoni. Fatigued and discontented, however, "the best cavalry officer in Europe," as Napoleon called him, also abandoned the army, and took the road to Naples. On his return to his capital, he made overtures to the court of Vienna, with a view to the formation of an alliance with Austria; but the campaign of 1813 soon afterwards opened, and as the first events proved favourable to Napoleon, Murat quitted Naples, and once more repaired to the headquarters of the French army. After the loss of the battle of Leipsic he withdrew to his states, and considering the star of Napoleon as for ever eclipsed, he opened his ports to the English, and renewed the negotiations for the accession of Naples to the European alliance against France.

His title of "king" had turned his head; and he incurred the double reproach of treachery and ingratitude, without deriving the slightest advantage from his dereliction of principle. Though brave as a lion in the field of battle, he showed himself one of the weakest of men when not in presence of the enemy. He had no moral courage. His invasion of Italy after the return of Napoleon from Elba was in every view a most headlong and irrational proceeding. In the space of two months he had lost his army, his fleet, part of his treasures, his crown, and even his field equipage; and now, after the second abdication of the man in whose fortune alone he could repose any hope for the future, all seemed irrecoverably lost. He escaped to the island of Corsica, where he had many partizans, and began to form new projects. Resolved to make an attempt to recover his power, he sailed from Corsica for Italy on the 28th of September 1815, with seven transports, containing 250 men, and on the 8th of October reached the Gulf of St Euphemia, where one only of his barks had rejoined him, the rest being separated in a gale of wind. When he landed at Pizzo he was accompanied by only thirty men, and knew not what course to follow. Having attempted to raise the country, the inhabitants flew to arms, and attacked his troop, upon which the two small vessels immediately stood out to sea. Murat attempted to launch a fishing-boat which he found upon the beach; but the task exceeded his strength, and escape was impossible. Having been made prisoner, he was lodged in the castle of Pizzo, tried by a military commission, condemned, and sentenced to be shot. The judgment of the court was carried into execution on the 13th of October, when this singular man, whom death had spared in a hundred battles, fell ingloriously in an obscure town of Calabria, the victim of his own folly and ambition. He appears to have died in a manner worthy of his reputation for courage. He refused to allow his eyes to be bandaged, saw the arms charged, placed himself so as to receive the concentrated fire of the soldiers, and exclaiming "Sauvez le visage, visez au cœur," instantly fell dead under the discharge. Murat perished in the forty-eighth year of his age, after having experienced every variety of fortune; indeed, he was a man whose destiny may, in some respects, be considered as the most extraordinary in modern times. Sprung from the lowest class of society, and raised to supreme rank, his elevation was the more surprising that he had neither the great qualities nor the great vices which seem to command events. Fortune had so blinded him, that he neither perceived the inevitable dangers with which the fall of Bonaparte and the restoration of the Bourbons had surrounded him, nor could he turn to account the resources which circumstances still placed in his power. (J. B.—E.)

MURATORI, LUDOVICO ANTONIO, a learned Italian scholar and antiquary, was born at Vignola, in the duchy of Modena, on the 21st of October 1672. He received his elementary education at the college of Modena, where he signalized himself by his application and the rapidity of his progress in the ancient languages and in literature. He then entered the university, where he passed through the ordinary curriculum, applying himself with equal ardour to the study of philosophy, jurisprudence, and theology. Father Bacchini, the learned librarian of the Duke of Modena, inspired him with a taste for historical researches, and taught him to read manuscripts; and so much did he profit by his advantages, that at the age of twenty he was considered a prodigy of talent and erudition. In 1694 he was called to Milan by Count Carlo Borromeo, who had appointed him a keeper of the Ambrosian Library. But before quitting Modena he wished to take his degree of Doctor *in utroque jure*; and the theses which he maintained on this occasion were universally applauded. Having established himself at Milan, and taken sacred orders, Muratori

Murcia.

entered upon a course of study and research calculated to justify the hopes which his talents had inspired; and having made a selection from the numerous manuscripts intrusted to his care, he published them, with dissertations intended to throw light upon various disputed points in archæology. The reputation he thus acquired was great, and the Duke of Modena, regretting that he had parted with a man who seemed destined to attain such distinction, offered him, as an inducement to return, the situation of conservator of the public archives of the duchy, together with that of keeper of his library, vacant by the resignation of Father Bacchini. Muratori returned in 1700 to Modena, which he never quitted, except to visit the public collections of the principal cities of Italy. In 1734 Apostolo Zeno offered him the chair of belles-lettres in the university of Padua; but Muratori declined accepting a situation which would have withdrawn him from his favourite pursuits. The publication of a number of valuable tracts on the history of Italy during the middle ages, besides various learned dissertations, added every year to his growing reputation; and this indefatigable writer also found leisure to cultivate polite literature, nay, even to take part in the theological discussions which then occupied so much of the public attention. Indeed, all the journals and all the literary collections of the time were enriched with some of his productions. The freedom with which he communicated the result of his researches, had put him in communication with the most distinguished scholars of Italy, France, and Germany, who had recourse to him on all subjects of difficulty. Literary societies vied with one another in sending him diplomas of admission; and many who had attained eminence in different departments of literature paid him the homage of inscribing to him their works. A rumour got afloat that he was heterodox, which induced him to write to Benedict XIV. repudiating the charge. His holiness assured him, however, that he had found nothing reprehensible in his writings. The health of Muratori, enfeebled by excessive labour, at length declined; and after languishing for some time, he died on the 23d of January 1750, at the age of seventy-seven. He was buried with much pomp in the church of Santa Maria di Pomposa, whence his remains were in the year 1774 transported to that of St Augustin.

Of the works of Muratori, sixty-four in number, a detailed list will be found in the *Biblioteca Modenese* of Tiraboschi (tom. iii., pp. 326-346). The principal are,—*Anecdota ex Ambrosiana Bibliotheca*, Milan, 1697, 1698; Padua, 1713, 2 vols. 4to; *Vita e Rime di Maggi*, Milan, 1700; *Della Perfetta Poesia Italiana*, Modena, 1706, 2 vols. 4to; *Anecdota Græca*, Padua, 1709, 4to; *De Ingeniorum Moderatione in Religionis negotio*, Paris, 1714, 4to; *Delle Antichità Estensi ed Italiane*, Modena, 1717, 2 vols. folio; *Rerum Italicarum Scriptores præcipui, ab anno 500 ad 1500*, Milan, 1723-1751, 29 vols. folio; *Delle forze dell' Intendimento Umano*, Venice, 1735 and 1745, 8vo; *De Paradiso Regniqve Cælestis gloria liber*, Verona, 1738, 4to; *Antiquitates Italica medii ævi*, Milan, 1738-1743, 6 vols. folio; *Novus Thesaurus Veterum Inscriptionum*, Milan, 1739-1742, 6 vols. folio; *De Superstitione vitanda adversus Votum Sanguinarium pro immaculata Deiparæ conceptione*, Venice, 1740 and 1742, 4to; *Cristianesimo felice nelle missioni del Paraguai*, Venice, 1743, 4to; *Annali d'Italia dall' era volgare sino all' anno 1749*, Venice, 1744-1749, 12 vols. 4to; *Liturgia Romana Vetris tria Sacramentaria complectens*, Venice, 1748, 2 vols. folio; *Della Publica Felicità oggetto de' buoni principi*, Lucca, 1749; *Lives of Segneri, Ligonius, Orsi, Tassoni, and others*; Dissertations, in various collections; *Lettere*, Venice, 1783, 2 vols., preceded by a Life of Muratori from the pen of Lazzari, professor of elocution in the Academy of Pesaro. The works of Muratori were published at Arezzo, 36 vols. 4to, 1769-80, and at Venice, 48 vols. 8vo, 1790-1810. (J. B.—E.)

MURCIA, a province in the S.E. of Spain, between 37. 19. and 38. 39. N. Lat. and 0. 50. and 3. 5. W. Long.; and constituting the greater part of the ancient kingdom of Murcia, broken up in 1833. The kingdom of Murcia had a superficial extent of about 3000 square miles, and had the following boundaries:—N., La Mancha; E., Valencia; S., the Mediterranean; and W., Granada. The province has

Murcia.

about 1200 square miles of surface, and is bounded N. by the province of Albacete, W. by that of Almeria, S. and E. by the Mediterranean; having a coast-line of between 70 and 80 miles. East of Cartagena the coast is low and sandy; W. of that port it consists, as far as Granada, of a line of precipitous cliffs, having only two other smaller ports, Aguilas and Almazarron. Of this coast the most remarkable feature is the Mar Menor, a kind of lagoon at the eastern extremity, 10 miles long and 3 broad, separated (except a small opening) from the sea by a narrow sandbank. The surface of the province is nearly equally divided between hill and plain. The most considerable mountains are those of the Espuña and those of the Carrascoy series,—the former bounding the province to the W., and having sometimes an altitude of 3000 feet; the latter, rising in the midst of the vast plain (El Campo) S.W. of the capital, extending eastwards and ending in Cape Roch. The Almagrera chain enters the province on the S. and W., and ends in Cape Palos. These mountains are of igneous formation, abound in copper, lead, and silver, and contain some singular caves, of which that of Barquillo and that of Don Juan near Cartagena are remarkable for their extent and the beauty and magnitude of their coloured crystals. The province is chiefly watered by the River Segura, and its affluents the Mundo, Mula, &c. The Segura has a tortuous course, W. to E., of about 170 miles, of which 92 are included in Murcia; and its waters are made available for irrigation by means of reservoirs, tanks, and canals,—Moorish devices, without which the whole province would be as sterile as an African desert. The *huertas*, or tracts watered in this way, are of great fertility, producing abundance of cereals, the palm, the orange, carob tree (St John's bread), silk, wine, &c. The principal roads of the province—those from Albacete to Cartagena, from Lorca to Andalusia, and from Murcia to Alicante—are bad, the last-mentioned often impassible during winter. Those in the N. are much worse, from the greater difficulty of the ground.

Wheat, barley, oats, hemp, and legumes are grown in the plains; also in the *secanos*, the barilla or soda plant, an exhausting crop. In the *huertas* of Calasparra, in the N., rice is cultivated for domestic consumption. In the huerta of Murcia, a fertile valley inclosed by hills and watered by the Segura, extending about 17 miles in length, by about 5 in breadth, are extensive plantations of mulberry for the silk-worm. Citrons, lemons, oranges, &c., are especially abundant in the valley of Ricote. Wine is grown to some extent, but under the discouragement of heavy duties. In the uncultivated hilly country the *esparto*, a rush used for mats and sandals, grows, especially in the plains of Mula, Albudate, Ricote, and Lorca, and in the marshes of Jaravia and Cope. Oil is grown, and is an increasing product, in the partidos of Murcia, Mula, Lorca, and Cartagena.

The chief mineral products are sulphur, alum, copper, lead, and silver. The mining industry of the province has recently received an impulse, many of the ancient mines having been re-opened, and new ones discovered. Lead and silver are found in the mountains on the coast, between the Bay of Porman and that of Villaricos. In the partido of Cartagena, the *escoriales* (slags) of the ancient mines have been worked with success. Sulphur is found in conjunction with other minerals; also pure in great quantities at the conflux of the Mundo with the Segura. At Calasparra and Maratalla are establishments for extracting it. White marbles and other ornamental stones are found; and there are considerable mines of alum and red clay at Mazarron.

The population is chiefly agricultural, and the products of the soil are manufactured elsewhere; even the silk grown in the huerta being mostly exported in a raw state. Besides that of silk, and silk fabrics to some extent, there are manufactures of salt, from salt springs and the salt

Murcia. marshes on the coast; of numerous articles, especially cables from the esparto, of white paper in Caravaca, of brandy in Pliego and Calaspana. (See CARTAGENA, and LORCA.)

From the three ports of Cartagena, Aguilas, and Mazarron, are exported cereals, barilla, esparto (raw and manufactured), silk, fruits, and minerals. Grain and other articles are exported to Algiers. The silk of the province finds a market in South America, by way of Cadiz. By Cartagena are imported colonial products, sugar, cacao, &c. The imports of Aguilas and Mazarron are chiefly cereals from Andalucia. From La Mancha are imported wheat and saffron, and cattle from La Jaen. Owing to the proximity of Oran and Gibraltar, a good deal of smuggling is carried on. For the internal trade there is the annual fair of Murcia, the capital, 24th August to 8th September; of Lorca, 8th September; also of Caravaca, Cieza, &c.

Primary instruction is extremely scanty and deficient, and the crime and ignorance of the Murcians are proverbial in Spain. In 1844 a normal seminary was established, and an improvement is said to have already taken place. The seminary of San Fulgencio being in decay, there is a total want of the higher instruction.

The agricultural Murcians of the north differ considerably from the commercial people of the south; the former are grave, dull, apathetic, laborious, and tenacious of ancient manners. The *huertanos* of Murcia preserve much of the Moorish in manners and physiognomy, and a good deal of emigration to Algiers has taken place since the French occupation of that country. Pop. about 400,000.

MURCIA, a city of Spain, capital of the province of that name, is situated on the River Segura, in 38. N. Lat., and 1. 11. W. Long., nearly in the centre of the valley called the Huerta de Murcia. The Segura divides the city into unequal parts. The suburb of San Benito, on the right bank, is connected with the principal division of the city by a very fine stone bridge of two arches. It enjoys a delicious climate,—a kind of perpetual spring; an advantage which it owes mainly to its sheltered position. It is surrounded by a brick wall, erected during the civil war, and has three principal gates on the N., S., and E., besides various smaller entrances. The streets are mostly broad, straight, and well flagged; that of La Plateria is the principal street in the city, and a great resort of loungers, being covered with awnings of canvas in hot weather. The principal plaza is that of San Domingo, in which is a promenade planted with orange and other trees, and much frequented. The houses are mostly of two storeys, the lower being inhabited in summer. The finest building in the city is the cathedral (1388–1467): the fine Corinthian columns of its façade are the work of D. Jaime Brot, in 1737. The interior is of semi-Gothic architecture, but is not equal to the exterior. The bell-tower, begun 1521, and finished 1766, is of three stages, unequal in point of merit, and contains a peal of twenty bells. The episcopal palace of the see of Cartagena, erected 1748–52, is one of the finest edifices of its kind in Spain, and has a commanding situation. Near the palace are the colleges of San Fulgencio and San Isidoro, which have the appearance of a single edifice. The other remarkable buildings are—the hospital of San Juan de Dios; the silk and saltpetre manufactories, on the N.; and the Alhordiga, a building for the deposit of grain. There are eleven parish churches, two hospitals, with a founding hospital and a house of refuge. The seminary of San Fulgencio, founded in 1592, has since 1823 been in a state of decay. The institute of secondary instruction was founded first in 1837, the rents of various suppressed religious houses being appropriated; it has at present two professorships of Latin, two of mathematics, and chairs of philosophy, natural history, chemistry, and general literature. A normal school was founded in 1844 for the improvement of the education of the province, and there are numerous

private schools in the city. In the suburb of San Benito, on the right bank of the Segura, is a Plaza de Toros rarely used.

The surrounding country, as far as the huerta extends, is very beautiful, and richly covered with the olive and mulberry. The olive and the vine are cultivated on the slopes of the surrounding sierras, but without much success. Silk is the most important product, amounting on an average to L.150,000 yearly; wheat, barley, &c., are largely grown, and all kinds of fruit. But few cattle are reared. There are manufactures of silk and silk cloth in the town; also of woollen cloths, of soap, earthenware, and some other articles, but to no great extent.

The province of Murcia was the first possession of the Carthaginians in Spain, and the city was, during the Moorish occupation, one of the seven capital cities of the seven military divisions of Spain, A.D. 787. It was taken by D. Alfonso, son of St Ferdinand, in 1240. Murcia was plundered by General Sebastiani in 1810, and in 1812 suffered from the attack of a detachment of Soult's army. On the 21st of March 1829 an earthquake caused a good deal of damage in the city, the cathedral being much injured. Pop. (1844) 55,053.

MURE, SIR WILLIAM, a Scottish poet, was the eldest son of Sir William Mure of Rowallan, and was born about 1594. Before his twentieth year he had written some English verses, and had attempted a version of the story of Æneas and Dido. In 1617 the visit of the King to Scotland called forth from Mure a poetical address, which is still preserved in the collection entitled *The Muse's Welcome*. For some time after the death of his father he passed his days in rural retirement, adorning the grounds and mansion of his family estate. The outbreak of the civil commotions of 1637 summoned him to action. Adopting the popular side, he served in the first army that was raised against the King, sat in the convention that ratified the Solemn League and Covenant with England in 1643, joined the parliamentary troops in the following year, and was wounded at Long Marston Moor. Sir William Mure died in 1657. Some of his poems, and an account of his life, are given in a book entitled *Ancient Ballads and Songs, chiefly from Tradition, Manuscripts, and scarce Works, with Biographical and Illustrative Notices, including Original Poetry*, by Thomas Lyle, London, 1827.

MURET (or **MURETUS**), MARC ANTOINE, a celebrated grammarian, was born at the town of Muret, near Limoges, in 1526. At an early age he cast off the uncongenial discipline that his teachers imposed upon him, and resolved to educate himself. Under the friendly eye of the elder Scaliger his progress in classical studies was so rapid, that at the age of eighteen he was invited to deliver lectures on Cicero and Terence at the college of Auch. After passing the next few years in teaching the ancient languages at Villeneuve-d'Agen, Poitiers, and Bordeaux, he was promoted to the chair of philosophy and civil law in the college of St Barbe at Paris. His lectures soon attracted notice by the lucid, elegant, and flowing style in which they set forth the most uninteresting legal details. Numbers, including the King and Queen, flocked to hear them. Yet envy at length marred his popularity by accusing him of the most unnatural sensuality. He was thrown into prison, and was on the eve of destroying himself, when the exertions of his friends secured his liberation. Retiring to Toulouse, he was pursued by the calumny, and barely escaped being burnt as a sodomist and heretic. His next place of refuge was Venice. There he published several of those clear and learned commentaries on the classics which constitute the corner-stone of his fame. But there also the relentless scandal found him out and drove him to Padua. By this time his character was gradually vindicating itself; his accomplishments were recommending him to the friendship of eminent literary men; and the malicious

Murillo.

whisperings of his former friends, Lambin and the younger Scaliger, were in vain attempting to re-kindle the flame of persecution against him. In 1559 he was invited to Rome to take up his abode at the court of Cardinal Ipolito d'Este, a munificent patron of letters. The rest of his life was passed in unclouded prosperity. He was caressed by popes and cardinals, crowded audiences applauded his lectures on philosophy and theology, and when he entered into holy orders in 1576 several rich benefices were provided for him. He died at Rome in June 1585. Regarding his rhetorical powers, his pupil Montaigne represents him as that "Marc Antoine Muret whom France and Italy recognised for the best orator of his time." A collection of his works, published by Ruhnken, in 4 vols. 8vo, Leyden, 1789, contains, among other productions, *Juvenilia et Poemata Varia*; *Varia Lectiones*; *De Origine Juris*; *De Legibus et Senatusconsultis*; *Notæ in Justitiani Institutiones*; and *Orationes*. The verses of Muret are nothing higher than a collection of poetical expressions hiding prosaic and common-place ideas. His notes and commentaries, however, on ancient authors are still valuable.

MURET, a town of France, in the department of Upper Garonne, is situated at the confluence of the Bheze and the Garonne, 11 miles S.S.W. of Toulouse. It is well built, principally of brick; and has manufactures of woollen stuffs, leather, earthenware, and brandy; and a considerable trade in cattle. It is celebrated in history for the siege it sustained in 1213 from Peter II. of Aragon, and for the battle fought in the same year, beneath its walls, between that monarch and Simon de Montfort, in which the former was defeated and lost his life. Pop. 4213.

MURILLO, BARTOLOMÉ ÉSTEVAN, the greatest ecclesiastical painter of Spain, was the son of Gaspar Estevan and Maria Perez, and was born at Seville in 1617. In accordance with a frequent Andalusian custom, he assumed the surname of his maternal grandmother, Elvira Murillo, in addition to that of his father. His parents having been struck with the precocious sketches with which the boy was accustomed to adorn whatever available surface came in his way, wisely resolved to place him under the care of their relative, Juan del Castillo, the painter. Juan taught him all the mechanical parts of his profession with extreme care, and Murillo proved himself an apt and docile pupil. The artistic appliances of his master's studio were by no means abundant, and were often of the simplest kind. A few casts, some stray fragments of sculpture, and a lay figure, formed the principal aids available in those days for the Sevillian student of art. A living model was a luxury generally beyond the means of the school; but on great occasions the indefatigable youths would strip in turn, and lend an arm or a leg to be studied by their fellows. Objects of still life, however, were much studied by Murillo, and he early learned to hit off, with genial humour, the ragged urchins of Seville pursuing their adventures in the market-place. Murillo in a few years painted as well as his master, and equally as stiff. His two pictures of the Virgin, executed during this period, show how thoroughly he had mastered the style of his instructor, with all its defects. Castillo, however, although not a first-rate artist, was a very kind man, and his removal to Cadiz in 1639-40 threw his favourite pupil entirely upon his own resources. The fine school of Zurbaran was too expensive for the poor lad: his parents were either dead or too poor to help him; and he was compelled to earn his bread by painting rough pictures for the *Feria* or public fair of Seville. The religious daubs exposed at that mart were generally of as low an order as the prices paid for them by their rude purchasers. A *pintura de la feria* (a picture of the fair) was a proverbial expression for an execrably bad one; yet the street painters who thronged the market-place with their "clumsy saints and unripe Madonnas," not unfrequently

rose to be able and even famous artists. This rough-and-ready practice of the market-place doubtless increased Murillo's manual dexterity; but if we may judge from the picture of the "Virgin and the Child," still shown in the Murillo-room at Seville, as belonging to this period, he made but little improvement in colouring or in general strength of design. Struck by the favourable change which travel had wrought upon the style of his brother artist Pedro de Moya, Murillo in 1642 resolved to make a pilgrimage to Flanders or Italy in quest of further insight into the mysteries of his art. But how was he, already struggling for existence, and with a poor sister dependent on him, to raise the means necessary for such an expedition? The problem was a difficult one, but he gave it a brave solution. Having bought a large quantity of canvas, he cut it into squares of different sizes, which he converted into pictures of a kind likely to sell. The American traders at once bought up his pieces, and he now found himself sufficiently rich to carry out his much-cherished design. He placed his sister under the care of some friends, and without divulging his plans to any one, set out for Madrid. On reaching the capital, he waited on Velasquez, his fellow-townsmen, the great court painter, then at the summit of his fortune; and communicating to him his simple story, asked for some introduction to friends at Rome. The great artist liked what he saw of the manly youth, and in the noblest manner offered him lodging in his own house, and proposed to procure him admission to the royal galleries of the capital. Murillo accepted the generous offer, and here enjoyed the masterpieces of Italy and Flanders without travelling beyond the walls of Madrid. The next two years were chiefly spent in copying from Ribera, Vandyck, and Velasquez; and in 1644 he so greatly astonished the latter with some of his efforts, that they were submitted to the inspection of the King and the court. His patron now earnestly entreated him to go to Rome, and offered him letters to smooth his way; but Murillo, from whatever cause, preferred returning to his sister and to his native Seville.

The friars of the convent of San Francisco in Seville had about this time piously determined to adorn the walls of their small cloister in a manner worthy of their patron saint. The idea was a good one, but the brotherhood had no money; and after endless begging, they still found themselves incapable of employing an artist of name to execute the task. Murillo was needy, and offered his services; and after duly balancing their own poverty against his obscurity, the good friars ruefully shook their heads, and bade him begin. Like the rest of their fellow-mortals, they were but short-sighted, and little dreamt of the fame which was in store for the little cloister of Saint Francis. Murillo covered its walls with eleven large pictures of remarkable power and beauty,—displaying by turns the rich, strong colouring of Ribera, the life-like accuracy and truthfulness of detail of Velasquez, and the heavenly sweetness of Vandyck. Among them were to be found representations of San Francisco, of San Diego, of Santa Clara, and of San Gil. These pictures were executed in his earliest style, commonly called his *frio*, or cold style. It was, according to Ford, based on Ribera and Caravaggio, and was dark, with a decided outline. This rich collection is no longer to be met with at Seville. Soult, that ruthless plunderer of churches and hospitals, carried off ten of them, and Mr Ford is now in possession of the eleventh. The fame of these striking productions soon got abroad, and *El Claustro Chico* swarmed daily with artists and critics. Murillo was no longer friendless and unknown. The rich and the noble of proud and opulent Seville overwhelmed him with their commissions and their praises. He found that, after all, the distance was not so great between the squalid *Feria* and the temple of Fame. But genius has always a curious art of discovering the shortest road to eminence.

In 1648 Murillo married a rich and noble lady, Doña

Murillo.

Murillo. Beatriz de Cabrera y Sotomayor, of the neighbourhood of Seville, and his house soon became the favourite resort of artists and connoisseurs. About this time he painted the well-known "Flight into Egypt," and shortly afterwards changed his earliest style of painting for his *calido*, or warm style. His drawing was still well defined, but his outlines became softer, his figures rounder, and his colouring gained in warmth and transparency. His first picture of this style, according to Cean Bermudez, was a representation of "Our Lady of the Conception," and was painted in 1652 for the brotherhood of the True Cross, for which he received 2500 reales (L.26). In 1655 he executed his two famous paintings of San Leandro and San Isidoro, at the order of Don Juan Federigo, Archdeacon of Carmona, which are now to be seen in the cathedral of Seville. These are two noble portraits, finished with great care and admirable effect, but the critics complain of the figures being rather short. His next picture, "The Nativity of the Virgin," painted for the Chapter, is regarded as one of the most delightful specimens of his *calido* style. In the following year (1656) the same body gave him an order for a large picture of "San Antonio de Padua," for which he received 10,000 reales (L.104). This is one of his most celebrated performances, and still hangs in the baptistry of the cathedral. It was, however, "repaired" in 1833, which of course did not improve it. The grandeur of the design, however, and the singular richness of the colouring, may still be traced. The same year saw him engaged on four large pictures of a semi-circular form, designed by his fast friend and patron, Don Justino Neve y Yevenes, to adorn the walls of the church of Santa Maria la Blanca. The first two were meant to illustrate the history of the festival of "Our Lady of the Snow." The one represents the wealthy but childless Roman senator and his lady asleep and dreaming; the other exhibits the devout pair relating their dream to Pope Liberius. Of these two noble paintings, the Dream is the finest, and in it is to be noticed for the first time the commencement of his third and last style, known as the *vaporoso*, or vapoury. Here the well-marked outlines and careful drawing of his former styles disappear; the outlines are lost in the misty blending of the light and shade, and the general finish betrays more haste than was usual with Murillo. Want of time may have had much to do with it, as in the case of our own Turner and Wilkie. After many changes of fortune, these two pictures now hang in the Academy of San Fernando at Madrid. The remaining pieces executed for this small church were, "A Virgin of the Conception," and a figure of "Faith." "That well-known French dealer," Soult, laid his hands on these also, and they have not been recovered.

In 1658 Murillo undertook and consummated a task which had hitherto baffled all the artists of Spain, and even royalty itself. This was the establishing of a public academy of art. By superior tact and good temper he overcame the vanity of Valdés Leal and the presumption of the younger Herrera, and secured their co-operation. The Academy of Seville was accordingly opened for the first time on the 1st of January 1660, and Murillo and Herrera the Second were chosen presidents. The former continued to direct it during the following year; but the calls of his studio induced him to leave it, now flourishing and prosperous, in other hands.

Passing over some half-length pictures of saints, and a charming dark-haired "Madonna," painted in 1668 for the chapter-room of the cathedral of his native city, we enter upon the most splendid period of Murillo's splendid career. In 1661 Don Miguel Mañara Vicentelo de Leca, who had recently turned to a life of sanctity from one of the wildest profligacy, resolved to raise money for the restoration of the dilapidated Hospital de la Caridad, of whose pious guild he was himself a member. Mañara commissioned his friend Murillo to paint eleven pictures for this edifice of San Jorge. Three of these pieces re-

presented "The Annunciation of the Blessed Virgin," "The Infant Saviour," and "The Infant St John." The remaining eight also treat of scriptural scenes and subjects, and are considered Murillo's masterpieces. They consist of "Moses striking the Rock," the "Return of the Prodigal," "Abraham receiving the Three Angels," "The Charity of San Juan de Dios," the "Miracle of the Loaves and Fishes," "Our Lord healing the Paralytic," "St Peter released from Prison by the Angel," and "St Elizabeth of Hungary." These works occupied the artist four years, and in 1674 he received for his eight great pictures 78,115 reales, or about L.800. The "Moses," the "Loaves and Fishes," and the "San Juan," are still to be found at Seville; but the French carried off the rest. On these pictures Murillo evidently expended all his strength, and he has left in them an enduring monument of the grandeur of his genius. For compass and vigour the "Moses" stands first; but the "Prodigal's Return," and the "St Elizabeth," are said by Bermudez to have been the most perfect of all as works of art. They can never, however, display the same excellences elsewhere as when hanging in the light and position which the artist designed them to occupy. The front of this famous hospital was also indebted to the genius of Murillo. Five large designs in blue glazed tiles were executed from his drawings. He had scarcely completed the splendid undertakings for this edifice, when his favourite brown-frocked Franciscans again solicited the aid of his pencil. He accordingly executed some twenty paintings for the humble little church known as the Convent de los Capuchinos. Seventeen of those Capuchin pictures are still preserved at the Museum of Seville. Of these the "Charity of St Thomas of Villaneuva" is reckoned the best. Murillo himself was wont to call it "*su lienzo*" (his own picture). Another little piece of extraordinary merit, which once hung in this church, is the "Virgin of the Napkin," believed to have been painted on a *servilletta*, and presented to the cook of the Capuchin brotherhood as a memorial of the artist's pencil.

In 1670 Murillo is said to have declined an invitation to court, preferring to labour among the brown coats of Seville. Eight years afterwards, his friend the Canon Justino again employed him to paint three pieces for the Hospital de los Venerables. They were severally the "Mystery of the Immaculate Conception," "St Peter Weeping," and "The Blessed Virgin." The last mentioned is said by Mr Townsend, an eminent critic, to be the most charming of all the works of this artist. (*Journey through Spain in 1786-7*, vol. iii, p. 297.) As a mark of esteem, he next painted a full-length portrait of his patron the Canon Neve, in which all the artist's skill is visible. The sleek spaniel reposing at the feet of the priest has been known before now to call forth a snarl from a living dog as he approached it. His portraits generally, though few, are of great beauty. Towards the close of his life Murillo executed a series of pictures illustrative of the life of "the glorious doctor" for the Augustine convent at Seville. This brings us to the last work of this great artist. Mounting a scaffolding one day at Cadiz to execute the higher parts of a large picture of the "Espousals of St Catherine," on which he was engaged for the Capuchins of that town, he stumbled, and fell so violently, that he received a hurt from which he never recovered. The great picture was left unfinished, and the artist returned to his beloved Seville only to die. He died as he had lived, a humble, pious, brave man, on the 3d of April 1682. He left behind him two sons and a daughter, his wife having died before him. His body was laid in the church of Santa Cruz, and by his own desire was covered with a stone slab bearing his name, a skeleton, and the words "*Vive moriturus*." Soult and his Vandals sacked this church, and nought is to be seen of it now but a heap of rubbish. Digging through this heap in 1823, the Sevillians found a quantity of bones in a vault, which

Murphy.

they piously closed up again. Let us hope that no foot stirs rudely that mound of ruins where rest the ashes of Murillo.

If Velasquez holds the first place as the Spanish court painter,—as the delineator of masculine and intellectual subjects,—Murillo has the undoubted pre-eminence as the religious artist,—as the painter of female and infantine grace. Of the old masters, and of what is called the antique, Murillo knew little. He painted only what he saw; and hence all his works are intensely Spanish. His representations of his favourite subject, "The Immaculate Conception," stand unrivalled for grace and feeling; and hence the epithet often applied to him of "*El Pintor de las Concepciones*." As a painter of landscapes he stands next to Velasquez among Spanish artists. Sir David Wilkie, in comparing these two great painters, remarks, "Velasquez, by his high technical excellence, is the delight of all artists; Murillo, adapting the higher subjects of art to the commonest understanding, seems of all painters the most universal favourite." (*Life of Wilkie*, vol. ii., p. 475.) (For further information respecting Murillo and his works, consult, especially, Stirling's *Annals of the Artists of Spain*, 3 vols., London, 1848; and the *Handbook for Spain*, by Richard Ford, London, 1855. For Murillo's position in the history of art, see FINE ARTS, and PAINTING.)

MUROM, a town of Russia, in the government of Vladimir, and 75 miles S.E. of the town of that name, stands on the left bank of the Oka. It has 18 churches, one of which is a cathedral. Leather and soap are the principal articles manufactured here; and in the neighbourhood there are rich iron mines. Some trade is carried on in corn. Pop. (1849) 9109.

MUROS, a town of Spain, in the province of Galicia, pleasantly situated on a bay of the same name, 55 miles S.W. of Coruña. The houses are old, and many of them in ruins. There are two principal streets and three squares; and the town contains several churches, a court-house, custom-house, prison, and school. Fishing and the manufacture of linen are carried on here; and there is some trade. The harbour is defended by a fort, but it is suitable for small vessels only. Pop. 4792.

MURPHY, ARTHUR, a dramatist, was the son of a Dublin merchant, and was born near Elphin, in the county of Roscommon, in 1727. From 1740 to 1747 he was a student of St Omer's College. He then entered the counting-house of his uncle, a merchant at Cork. But four years afterwards he was in London prosecuting literature as a profession, and publishing *The Gray's Inn Journal*, a periodical in the style of *The Spectator*. The drama was also occupying his attention. He produced the farce of *The Apprentice*, and appeared as an actor in the character of "Othello." His dramas were more successful than his acting. After treading the stages of Covent Garden and Drury Lane for one season each, he abandoned the profession. His next undertaking was the editing of a political periodical called *The Test*. In this, too, he was unsuccessful. He next turned his attention to the study of law, and was called to the bar by the Society of Lincoln's Inn in 1757. But the smallness of his practice forced him to have recourse to his former vocation of writing for the stage. Among his many popular dramas, *The Upholsterer*, in 1758; *The Way to Keep Him*, in 1760; *All in the Wrong*, in 1761; *The Grecian Daughter*, in 1772; and *Know your own Mind*, in 1777, were very successful, and secured for their author both fame and wealth. He also published in 1792 an *Essay on the Life and Genius of Dr Johnson*, and in the following year a translation of Tacitus. Towards the close of his life the office of a commissioner of bankrupts, and a pension of £200, were conferred upon him by government. He died in June 1805.

MURPHY, James Cavanah, an architect and antiquary, was born in Ireland, probably about the middle of the

eighteenth century, and resided for some time in Dublin. In 1789 he repaired to Portugal for the express purpose of examining the curious and uncommon Gothic architecture of the church of Batalha. His attention was also directed to the manners, trades, arts, and antiquities of the Portuguese provinces through which he passed. After his return he published, in 1792-96, *Plans, Elevations, Sections, and Views of the Church of Batalha*; in 1795, *Travels in Portugal*; and in 1798, *A General View of the State of Portugal*. These works were favourably received by the public, and their author was thus encouraged to proceed in the same line of research. Landing in Spain in 1802, he devoted the next seven years to the study of the architecture, arts, customs, and history of that country. The results of this investigation were published under the titles of *The Arabian Antiquities of Spain*, 1815; and *The History of the Mahometan Empire in Spain*, 1816. During the publication of this latter work Murphy died.

MURPHY, Robert, a mathematician, was the son of a poor shoemaker, and was born at Mallow in Ireland in 1806. At the age of thirteen, while working as an apprentice in his father's shop, he became known to certain gentlemen in the neighbourhood as a self-taught mathematician of wonderful precocity. Through their exertions, after attending a classical school in his native town, he was admitted to Caius College, Cambridge, in 1825. His talents gained for him the degree of B.A., and the position of third wrangler in 1829. He was elected in the same year a fellow, and in 1831 the dean of his college. But the temptations of prosperity were too strong for him. A course of extravagant dissipation soon led him into debt; his fellowship was sequestered for the behoof of his creditors; and he was obliged to leave Cambridge in December 1832. After living for some time with his relations in Ireland, he repaired to London in 1836, a penniless literary adventurer. He had already contributed several mathematical papers to the *Cambridge Philosophical Transactions*, and had published a work on Electricity, 8vo, Cambridge, 1833. His pen was now employed in writing for the "Library of Useful Knowledge" a *Treatise on the Theory of Algebraical Equations*. This work was published at London in 1839. He was labouring diligently to throw off the load of debt that still pressed heavily upon him, when a disease of the lungs cut short his career in March 1843.

MURRAY, DR ALEXANDER, an eminent philologist, was the son of a shepherd, and was born at Dunkitterick, in the Stewartry of Kirkcudbright, in October 1775. His elementary education was almost entirely self-acquired. The few books that a peasant's cot possessed were conned over with eager avidity as he sat by the family hearth in the evening, or lay amid his flock on the hillside during the day. At length, in 1789, he was enabled to attend the school of Minnigaff. The next five years were spent by him in studying in the school during the summer, in teaching the children of neighbouring families during the winter, and in greedily devouring knowledge at every opportunity. Books of all kinds were bought or borrowed; grammars and dictionaries of several languages, old and obscure treatises, histories, and poems, were perused and re-perused; he acquired a knowledge of the French, Latin, Greek, and Hebrew languages, and of the Anglo-Saxon, Welsh, and Arabic alphabets; he also wrote and prepared for publication a volume of poems. In 1794 his fame as a self-taught scholar, which had for some time been spreading in the neighbourhood, reached the ears of the Rev. Dr Baird of Edinburgh. By that gentleman's assistance he was enabled forthwith to enter the metropolitan university. In the course of two years a bursary was conferred upon him, and he began to study for the church. Though compelled to earn a scanty livelihood by giving private lessons, he continued, during every spare hour, to cultivate his literary

Murphy
||
Murray.

Murray. tastes, and to gratify his ever-growing desire for general information. He contributed several miscellaneous articles to the *Scots Magazine* and the *Edinburgh Review*. He also acquired an intimacy with all the European languages, and with the Geez, Amharic, and Abyssinian dialects. His knowledge of the last of these tongues recommended him, in 1802, for the task of editing Bruce's *Travels*. The edition appeared three years afterwards, in 7 volumes 8vo, accompanied by a Life of the author, and by copious philological and antiquarian notes. Shortly after this, in 1806, Murray was ordained assistant and successor to the minister of Urr in the Stewartry of Kirkcudbright, and succeeded to the sole charge of this parish in 1808. Meanwhile his edition of Bruce's *Travels* had been extending the fame of his scholarship, and had been opening up a road to honour and preferment. Accordingly, in 1811 he was employed to translate a Geez letter that had been sent to the king from the governor of Tigré; and in 1812 he was elected to the chair of oriental languages in Edinburgh. The degree of D.D. was also conferred upon him. Murray had now attained his proper position in life. At the same time, the stores of learning which his daily and nightly studies had amassed were beginning to assume a tangible form in a *History of the European Languages*. He set himself to his academical duties with more than his wonted enthusiasm. But long before the end of his first session his toil-worn constitution broke down, and he died in April 1813, at the age of thirty-seven. His philological work was edited in the same year by Dr Scot of Corstorphine. Another work of Murray's, *The Outlines of Oriental Philology*, had appeared in 1812.

MURRAY, John, an eminent chemist, was born in Edinburgh in 1778, and became a pupil of the celebrated Dr Joseph Black. Murray commenced his career as an apothecary in his native city; but soon began to give chemical lectures, which were remarkable for clearness of diction and a happy mode of illustration; so that he was justly considered one of the ablest and most popular teachers of chemistry in the present century. His *System of Chemistry*, in 4 vols. 8vo, went through four large editions, and was regarded as one of the very best works on the subject of that period. The first volume contains a very admirable statement of the doctrines of heat in relation to chemistry, as promulgated by Black and later philosophers. His smaller work, entitled *Elements of Chemistry*, in 2 vols., was also very popular. Dr Murray afterwards gave annual courses of materia medica and pharmacy, which were numerous attended; and he published a good *System* of those branches of medicine, which went through two editions. The publication of Playfair's admirable *Illustrations of the Huttonian Theory of the Earth*, in 1802, quickly called forth Murray's *Comparative View of the Huttonian and Neptunian Theories*. He was a zealous defender of the latter; and although the igneous origin of mineral bodies is now generally received, Murray has given us by far the best and most ingenious defence of the Neptunian doctrines ever given to the world. Dr Murray was the author of several papers in the *Transactions* of the Edinburgh Royal Society; one of the most interesting of which is "The Analyses of several Mineral Waters," in which he showed how salts obtained by their evaporation may be different from those actually dissolved in the waters. Dr Murray was much respected and esteemed by those who best knew him. He died prematurely, of disease of the heart, on 22d June 1820. (T. S. T.)

MURRAY, John, an eminent publisher, was the son of John M^r Murray, a bookseller in Fleet Street, London, and was born in November 1778. His education was received at the High School of Edinburgh and at several seminaries in England. In his fifteenth year he was left, by his father's death, to conduct the business, with the assistance of the

shopman, Mr Highley. On his coming of age, he made his assistant a partner. The partnership, however, was dissolved in 1803; and Murray began a career of publication unrivalled in the history of literature. His acuteness in detecting the merits of an author, and his knack of discerning the taste and wants of the public, soon rendered him one of the most successful of publishers. In 1807 he suggested to Canning the project of establishing a Tory periodical that might prove a worthy rival to the *Edinburgh Review*. The plan received the approval and hearty co-operation of Walter Scott in 1808; and in 1809 Murray published the first number of the *Quarterly Review*. In 1810 he sought the acquaintance of Lord Byron, whose high poetical powers were not yet recognised, made him a liberal offer for the first two cantos of *Childe Harold*, and commenced a literary connection with him which increased the fame of both publisher and poet. To other eminent authors he was equally generous. They received princely sums for the copyrights of their works. If the sale surpassed expectation, the stipulated price was increased, and sometimes even doubled. Such generous and highly honourable conduct soon raised Murray to the position of a patron of literature. Authors began to frequent the shop in Albemarle Street, to which he had removed in 1812. In his little back parlour there might have been seen of an afternoon such men as Byron, Scott, Crabbe, Southey, Washington Irving, and Lockhart, enjoying the racy and humorous conversation of the publisher. Among the many undertakings which he continued to conduct was the *Family Library*, begun in 1829. He sometimes published with great success works, such as the *Sketch-Book*, which had proved failures in the hands of other publishers. He died in June 1843, leaving his trade to his son, the present Mr John Murray.

MURRAY, Lindley, the author of a well-known English Grammar, was born at Swatara in Pennsylvania in 1745. After receiving his education at Philadelphia and New York, he entered his father's counting-house; but afterwards studied law, and practised at the bar until the breaking out of the war of independence, when he became a merchant, and soon amassed a handsome fortune, which enabled him to retire. He spent the remaining years of his life in England; and wrote *The Power of Religion on the Mind* in 1787, and his *English Grammar* in 1795. Several other school-books, both English and French, followed. His last publications were *A Selection from Horne's Commentary on the Psalms*, 12mo, 1808; and *The Duty and Benefit of a Daily Perusal of the Scriptures*, 1817. He died in February 1826. *Memoirs of Lindley Murray* were published by Elizabeth Frank, 8vo, York, 1826.

MURRAY, Sir Robert, one of the founders of the Royal Society, was the son of Sir Robert Murray of Craigie, and was born about the beginning of the seventeenth century. After serving in the French army, and rising to the rank of colonel, he returned to Scotland during the civil broils, and became an ardent and trustworthy supporter of Charles I. The downfall of the royal cause compelled him to betake himself once more to France. He appears to have dwelt there, and to have held a commission in the French army until Charles II. placed himself at the head of the Scots in 1650. His loyalty was rewarded in the following year by his being promoted to the important offices of justice-clerk and a lord of session in Scotland. These appointments, rendered null and void by the complete overthrow of the King's cause at Worcester, were confirmed on the restoration in 1660. It was at this time that Sir Robert Murray began to take a prominent part in a small club that had been founded by Robert Boyle, Lord Brouncker, and others, for the discussion of natural science, or, as it was then called, "the New Philosophy." He was present at the meeting of the 28th November 1660, when it was proposed

Murray.

Murray. "that some course might be thought of to improve this meeting to a more regular way of debating things." He undertook to advocate this proposal to the court. His suit was successful; an encouraging answer was returned by the government; and on the 15th July 1662 the club was incorporated by charter under the designation of "The Royal Society." Sir Robert was its first president. During the rest of his life he continued to be one of its most active members, and delivered before it several learned papers. He died in June 1673. Sir Robert Murray is described by Burnet, in his *History of My Own Times*, as "the wisest and worthiest man of that age."

MURRAY, William, Earl of Mansfield, a celebrated English lawyer, was the fourth son of David, Earl of Stormont, and was born at Perth on 2d March 1705. He received his education in England, first at Westminster School, and subsequently at Christ Church College, Oxford, where he took the degree of Bachelor of Arts in 1727, and that of Master in 1730. Having completed his academical studies, he shortly after became a member of Lincoln's Inn. Being called to the bar, Murray early acquired reputation as a speaker, and obtained a good practice in his profession. As early as 1736 we find him professionally employed against the bill of pains and penalties, which afterwards passed into a law, against the city of Edinburgh on account of the riotous murder of Captain Porteous. In 1738 he married Elizabeth, daughter of the Earl of Winchelsea; and in 1742 he was appointed solicitor-general, and chosen representative of Boroughbridge, for which place he was afterwards returned in 1747, and again in 1754. In 1748 he acted as one of the managers for the impeachment of Lord Lovat by the Commons, and in his observations on the evidence, in reply to the prisoner, displayed singular candour and ability.

In 1754 Mr Murray was appointed attorney-general in the room of Sir Dudley Ryder; and in 1756 he succeeded the same person as chief justice of the King's Bench. He took his seat on the bench on the 11th of November, and was immediately afterwards raised to the peerage by the title of Baron Mansfield. Owing to various reforms which he introduced, the business of the court increased to an extent never before known, and continued to be despatched with exemplary regularity. It is stated by Sir James Burrow, in the preface to his Reports, that at the sitting for London and Middlesex there were as many as eight hundred causes set down in a year, "and all disposed of."

During the very unsettled state of the ministry in 1757 Lord Mansfield accepted the office of chancellor of the exchequer, and was the means of effecting a coalition of parties, out of which was formed a strong and successful administration. In the same year he was offered the great seal, on the retirement of Lord Hardwicke, but declined it. His political sympathies were not on the popular side, and at the commencement of the reign of George III. he was marked out as an object of party rancour, and continued for many years exposed to violent and unsparing invective, the most vigorous specimens of which have come down to us in the *Letters of Junius*. The affair of Mr Wilkes' outlawry served to rekindle the animosity with which he had been regarded by the popular party, and exposed him to renewed attacks. On the day when judgment was to be given on this case, not only the court, but the whole of Westminster Hall and Palace Yard, were crowded with anxious spectators. Lord Mansfield took notice of the popular excitement which had been directed against the judges of the court, particularly himself; and declared his contempt for all the threats which had been employed to deter the court from doing their duty. "I honour the King," said he, "and respect the people; but many things acquired by the favour of either are, in my account, objects not worth ambition. I wish popularity; but it is that popularity which follows, not that which is run after."

In the beginning of 1770 Lord Mansfield was once more offered the great seal, which he again declined; and a similar offer, renewed the following year, found him equally inflexible. About the same time he was attacked, in both Houses of Parliament, on account of his direction to the jury in the case of Woodfall the printer, who had been prosecuted for a libel. He maintained the dangerous principle that the question of law belonged exclusively to the court, and that the only point competent for the jury to try was merely the fact of publication, leaving it to the judges afterwards to decide whether the matter published did or did not amount to a libel. In 1776 his lordship was raised to the dignity of earl.

During the excitement and lawlessness of June 1780 Lord Mansfield was marked out as an object of popular vengeance, and his house in Bloomsbury Square, with every thing it contained, including his library and manuscripts, were wholly consumed. His lordship submitted to his loss with calmness and dignity, and declined a proposed indemnification by the House of Commons.

From this time it seemed as if popular hatred had spent its force; and during the remainder of his life all parties united in a common feeling of respect and reverence for his character and virtues. Notwithstanding his advanced age, he continued until 1787 to discharge his judicial functions with his wonted regularity; but from that time his infirmities increased so rapidly, that in June 1788 he came to the resolution of resigning his office, and withdrawing into the shade of retirement. His health continued to decline, but his mental faculties remained unimpaired almost to the last. He died on the 20th of March 1793, in the eighty-ninth year of his age, leaving his immense fortune to his nephew Lord Stormont, who also, in virtue of a new patent granted in 1792, succeeded to his title.

As a politician, Mansfield had too little courage to be the leader, and too much ability to be the dupe, of any party. He was not a forward nor a frequent speaker, but reserved himself for occasions worthy of himself, and never spoke except on subjects which he had carefully considered. In debate he was eloquent as well as judicious; displaying wisdom and good sense, set forth in the clearest method. He affected no sallies of imagination nor bursts of passion, and he never condescended to personal abuse or virulent altercation. His character as a judge has always stood high, although his legislation was more successful in commercial law than in that of real property; and the depth of his legal learning has been frequently questioned. He was tolerant in matters of religion; and in private life he was easy, friendly, and engaging; extremely sensible of worth in other men, and ready upon all occasions to countenance and patronize it. (See *Life of Lord Mansfield*, by Henry Roscoe, in Lardner's *Cabinet Cyclopædia*.)

MURRAY, the principal known river of Australia, rises in the Australian Alps, or Warragong Mountains, in S. Lat. 36. 20., E. Long. 148. 15. It flows in a very irregular course towards the N.W., forming the greater part of the boundary between New South Wales and Victoria. In E. Long. 142. it takes a general direction towards the W., in 140. it turns S.S.W., and finally falls into Lake Victoria, and through it into the ocean, in S. Lat. 36. 30., and E. Long. 139. This river and its tributaries water a most extensive tract of country, comprising the whole of Victoria and New South Wales, with the exception of a narrow strip that extends along the coast. The length of the main river is not more than 700 miles; and though several of its affluents much exceed it in the length of their course, yet they are all inferior to it in the volume and rapidity of their water. Not far from its source it has a breadth of 100 yards; and in 143. E. Long., where it receives the Murrumbidgee, it is three or four times as broad. From its junction with the Darling, in E. Long. 142., to its mouth, the breadth of the river is on an average from 100

Murray. to 150 yards; and where it enters Lake Victoria it is about 200 yards wide, and often as deep as 10 fathoms. Thus, like most of the rivers of Australia, the Murray, while broad, full, and rapid in the higher parts of its course, becomes gradually less as it approaches the sea, receiving no tributaries for a considerable distance above its mouth, and flowing through a marshy and alluvial soil. The plain through which the Murray flows is in general low and flat, slightly sloping towards the sea, and in about 144. E. Long. the course of the river winds through extensive tracts of reeds. Further down, the banks are lined for a very long distance with trees, which give to the river the appearance of an avenue; and it is remarkable that the same kind of wood is never found on opposite sides. Below its junction with the Darling, the Murray forces its way between precipitous cliffs of limestone rock, which rise in some places to the height of 200 feet; but these, as the river approaches the coast, give place to lower undulating hills inclosing between them large tracts of marshy land overgrown with reeds. The river is very much subject to floods. Its annual rise is about 16 or 20 feet; but the waters of the Murrumbidgee frequently cause it to rise 30 or 40 feet above its usual level. When the river is in flood, it is navigable as far up as Albury, about 90 miles from its source; and steamers and barges now ply regularly as far up as that place, when there is sufficient depth of water, which is about six months in the year. The entrance into Lake Victoria from the sea is difficult, if not dangerous, owing to the violent surf and to the constant changes in the position of the channel, which is also very shallow. In order to avoid the inconveniences of this navigation, a tramway has been constructed for a distance of 8 miles, between Goolwa, on the Murray, and Port Elliot, on the ocean. This is now working in connection with the river steamers.

The tributaries of the Murray form the greater part of the entire system of that river. The Murrumbidgee rises in the same mountains as the Murray, a short distance to the north of that river, and flows for the most part of its course in a direction nearly parallel. The country through which it flows resembles, in its low, flat character, that near the Murray; and it passes through many tracts of marshy and reedy ground in its course. As it proceeds westward it is gradually diminished in volume and rapidity, and finally discharges its waters into the Murray. The Lachlan River rises in the mountains to the west of Sydney, and flows first W. and then S.W., until it is lost in marshes which are drained by the Murrumbidgee. The Macquarie rises in the same chain of mountains farther to the N., and flows in a N.E. direction; but it soon becomes gradually less, till it is absorbed in an extensive morass. The longest of the affluents of the Murray is the Darling, a river which rises in the N.E. of New South Wales, and flows in an irregular course towards the S.W., till it falls into the Murray. In the upper part of its course it receives many tributaries, of which the principal are the Balonne, from the N., which falls into it by several branches, and the Macquarie from the S.E., through the marshes in which that river ends. It also receives the River Bogan, which runs parallel to the Macquarie; but in the lower part of its course it has no important tributaries. The water of the Darling is salt near its source, but below its junction with the Bogan it is fresh, and quite fit for drinking. The flats through which the Darling flows, near its union with the Murray, differ from those of the latter river in the beauty of their scenery, and in being covered, not with reeds, but with the most luxuriant vegetation. Its current here is generally sluggish, and its waters, which are muddy, do not in general contribute much to increase the volume of the Murray; but, like all the Australian rivers, it is subject to inundations, and is very variable in its condition, sometimes rising 3 or 4 feet in the course of twenty-four hours. Its banks,

like those of the Murray, are thickly covered with timber. The navigation of the Darling is very uncertain; but it has been ascended as far as 30 miles above its confluence with the Murray. The basin of the Murray is bounded on the S. and E. by mountains, which skirt the coast, and which are known by various names at different parts. On the W. it is bounded by a range running N. and S., near the boundary between New South Wales and South Australia; and on the N. there is believed to be another range extending E. and W., and forming the watershed of the rivers of Australia. The general character of the basin of the Murray is flat. It is in some parts dry and destitute of water, and in others alluvial and marshy. The best part of this region is that at the N.E. corner, called Darling Downs, an extensive region of rich pasture grounds. This country seems to be very thinly peopled, and in some places, as far as the eye can reach, there is no trace to be seen of human habitations. This is almost the only portion of the interior of Australia that has been explored, and this has only been done in comparatively recent times. No attempt was made before 1813 to cross the mountains which form the eastern boundary of the Murray River system, and it was not till 1829 that its mouth in Lake Victoria was reached. In that year Captain Sturt followed the course of the Murrumbidgee from its source to the Murray, and that river down to the sea. The Lachlan and the Macquarie had been explored by Oxley in 1817 and 1818; and part of the upper course of the Darling was discovered by Sturt in 1828, who also penetrated, in 1844, for some distance up the Darling, and thence into the centre of Australia.

MURREE, in Hindustan, a sanatorium for British troops in the Punjab, situated on a hill between the rivers Indus and Jhelum, and established in the year 1851. The place is already attracting a considerable population. Barracks have been constructed, and houses are rising in every direction. Cherries, strawberries, raspberries, currants, apples, pears, and apricots are abundant. Elevation of the station above the sea, 7330 feet. Lat. 33. 54., Long. 73. 27.

MURVIEDRO (anc. *Saguntum*), a town of Spain, province of Valencia, is situated at the foot of a hill on the Palancia, 16 miles N. of Valencia. It is surrounded by Moorish walls, and there is a citadel on the summit of the hill. The town itself is irregularly built, with mean houses and narrow streets. It has two churches, several convents and hermitages, a town-house, custom-house, prison, hospital, schools, &c. Murviedro is more remarkable for its remains of antiquity than for any of its modern buildings; but most of these have been very much neglected, and many of the marble fragments have been built into modern edifices. The site of the ancient temple of Diana is now occupied by the convent of La Trinidad, which has several Roman inscriptions built into the wall. The plan of the ancient theatre may still be traced on the slope behind the town, and there are some remains of the circus in the neighbouring orchards. The inhabitants are chiefly employed in agriculture; but the town has several distilleries and flour and oil mills. The ancient town was a seaport, but the coast-line has now retired to the distance of 4 miles from the town. Corn, wine, fruits, and oil, from the surrounding country, are the principal exports. The fortifications are so strong that Murviedro is reckoned the key of Valencia. Pop. 5349.

MUSA, **IBN NOSSEYR**, a famous Mohammedan conqueror, was the son of a liberated slave, and was born A.D. 640. At the court of Damascus he rose high in the favour of Abd-ul-aziz, the brother of the Caliph Abd-ul-malek. It is probable that he was early employed in high military offices; but not until his fifty-ninth year did his talents for war obtain full scope. He was then appointed governor of Eastern Africa, and was entrusted with the subjugation of the wild tribes that bordered on that province. His armies, under

Murree
||
Musa.

Musa.

himself and his sons Abdullah and Merwan, were everywhere triumphant. They pursued the Berbers into their native deserts, and forced them to adopt the faith of Islam. Marching westward through Northern Africa, they did not halt in their victorious career until, in 709, they had stormed the cities of Tangiers and Ceuta, and had encamped by the shores of the Atlantic. At this juncture, when Musa was beginning to look around for new fields of conquest, his aid was solicited by the sons of Wittiza, the late King of Gothic Spain, who were endeavouring to wrest their father's crown from the brave usurper Roderick. The occasion was eagerly seized by the Mohammedan conqueror. An expedition was forthwith sent into Spain, and returned soon afterwards laden with booty. A still greater force, under Tarik Ibn Zeyad, landed at Gibraltar in April 711; and in September of the same year, Roderick was defeated and slain in a great battle on the banks of the Guadelete. No sooner had Musa heard of this victory, than, jealous lest he should be eclipsed by his own lieutenant, he commanded Tarik to prosecute his successes no further, and at the same time he set out in person for the scene of war. But long before his arrival, in 712, his orders had been disregarded, and Cordova, Malaga, Granada, Orihuela, and Toledo had been captured by the victorious troops. Chafing under this insult to his authority, he set himself with vigour to bring his reputation out of the shade into which it had been cast by the exploits of Tarik. Carmona, Seville, Beja, and Niebla fell before his attack. After an arduous siege he took Merida, and then marched towards Toledo to meet Tarik. No sooner had he met the disobedient lieutenant, than he struck him with his whip in the sight of the whole army, upbraided him for his neglect of orders, and threw him into prison. He was even meditating his death, when an order came from the caliph to set him at liberty and restore him to his command. Tarik was accordingly reinstated in the favour of his superior, and was placed at the head of a division. Then Musa prepared to subjugate the rest of the country. Entering Aragon, he marched northward, subduing Saragossa and its districts, and receiving the submission of the inhabitants. In a short time Spain was almost entirely under his power. His next enterprise was to cross the Pyrenees, and to make an inroad into France. But as he met with no encouraging success, he returned to Spain, and addressed himself to the invasion of Asturias and Galicia. An order from the caliph to repair to Damascus did not deter him from executing his project. He was at Lugo, in the midst of new conquests, when a second and more peremptory command reached him. With extreme reluctance he relinquished the design he had been entertaining of carrying his conquests westward through Gaul, Italy, and Germany, and of thus opening a direct communication between Syria and Spain. Consigning the government of Spain into the hands of his son Abd-ul-aziz, he embarked for Africa, on his way to the East, in 713. On his landing, he astonished the inhabitants of the districts through which he passed by the pomp of his march. Numerous waggons and camels, laden with costly spoils and treasures of gold, silver, and precious stones, went before him. Behind him marched in long array 30,000 captives, including 400 nobles in gorgeous attire. As he approached Damascus, he is said to have been met with the intelligence that the Caliph Alwalid was at the point of death, and that Suleyman, the heir to the crown, desired him to delay his entrance into the city, and the exhibition of the Spanish spoils, until the commencement of the new reign. This request Musa set aside, and marched straight into Damascus. Accordingly, on the death of Alwalid, the resentment of Suleyman fell heavily upon him. All those illustrious services by which he had added so many territories to the government of the caliph were forgotten. He was cast into prison, lacerated with

scourges, and exposed to the sun till almost lifeless. A severe fine was then imposed upon him, which stripped him of his immense wealth, and left him to beg his bread from door to door. In the midst of his affliction, the head of his murdered son Abd-ul-aziz was shown to him by the tyrant. At length, overborne with misery and old age, Musa died at Wadal-Kora in 717. (See *History of the Mohammedan Dynasties in Spain*, London, 1840.)

MUSÆUS, an ancient Greek poet, flourished at Athens in the mystic period of Grecian history. Some legends represent him as the son of Orpheus. At any rate, he is generally supposed to have been the disciple and imitator of that famous poet. He presided over the Eleusinian mysteries, and in that capacity he composed and sung his hymns. A hill near the citadel of Athens, to which he was wont to resort for meditation and study, and on which he was afterwards buried, is said to have been called *Museum* after him. His works are only known in a few detached passages quoted by Plato, Pausanias, Clemens Alexandrinus, Philostratus, and Aristotle. They are said to have consisted of oracles, precepts addressed to his son Eumolpus, a hymn to Ceres, a theogony, a poem on the War of the Giants, a treatise entitled *Sphæra*, and a work on Mysteries.

MUSÆUS, a grammarian, supposed by the elder Scaliger to be the same as the preceding, is considered, from the internal evidence of his style, to have flourished in the later periods of the Roman empire. His only extant work, a poem on the famous love story of Hero and Leander, was first discovered in the thirteenth century; and ever since that time it has continued to be a great favourite with scholars. Among the many editions, those of Passow (Leipsic, 1810) and Schæfer (Leipsic, 1825) are the latest. It has been translated into English by Stapleton, into German by Stolberg and Passow, and into French by Marot. Marlowe's poem is rather a paraphrase than a translation of Musæus.

MUSCAT, or MASKAT, a city and seaport of Arabia, capital of Oman, is situated at the head of a small cove on the Indian Ocean, in N. Lat. 23. 38., E. Long. 58. 42. It is built along the shore in the form of a horse-shoe, and is surrounded by steep hills, through which it communicates with the interior by only one pass. These hills are occupied by a circle of forts, which defend the town, and, along with the domes and minarets of the mosques, present a very fine appearance when seen from the sea. The interior of the city, however, is very far from bearing out the impression which a distant view produces on the traveller; most of the houses being mere mat-built huts; and even the better class, of which there are a few, being seldom more than one storey in height. The streets are very narrow, and partly shaded from the sun by mats of palm-leaves laid across from roof to roof; and the numerous and generally crowded bazaars are extremely dirty. The principal buildings in Muscat are the residences of the imaum, of the governor, and of some of the other public officers. The heat in the town is extreme, in consequence of its being surrounded by bare rocks; the temperature is generally as high as 90° in the shade. The harbour is very good, being sheltered from every wind except the north; but with some winds it is not easy for vessels to enter. A little to the W. of Muscat is another bay, less sheltered, which opens to the N.E., and on which the town of Matarah stands. The climate here is more temperate; and here many of the rich merchants of Muscat fix their residence. Muscat derives importance from its natural strength and defences, from its excellent harbour, and from its commanding position at the mouth of the Persian Gulf. The surrounding country is dry and barren; and the inhabitants depend principally on trade for their means of subsistence. The manufactures are few, consisting chiefly of sugar and coarse cloth. An extensive trade is carried on through Muscat between Arabia, Persia, and India. Cloth and corn are

Musæus
||
Muscat.

Musculus.
||
Muses

the principal articles of import, and the annual value of these is estimated at more than L.600,000. The exports consist of dates and madder, which are sent to India; sharks' fins to China; salt fish, horses, asses, hides, &c. Commercial transactions are here carried on principally by means of bullion and pearls. The harbour abounds in fish, and pearls may be obtained in the gulf not very far off; but the fishery has been for a considerable time neglected. The inhabitants of Muscat are a very mixed race, consisting of Arabs, Persians, Hindus, Syrians, Koords, Afghans, Belooches, &c.; and the prevailing language is a sort of corrupt Hindustanee, the use of the Arabic being confined to the native Arabs. The Sultan of Oman, whose capital is Muscat, is generally known by the ecclesiastical title of Imaum or Iman of Muscat; and his dependencies extend along the shores of Arabia and Africa as far south as Zanzibar. The present ruler ascended the throne, at the age of sixteen, in 1803; his father having been killed in 1802 by the pirates who then infested the Persian Gulf, and his uncle, who assumed the power as regent, having been murdered the year after. The beginning of his reign was disturbed by the pirates and by the Arab tribe of Beni-boo-Ali, who joined with them in attempting to introduce by force the doctrines of the Wahabee sect of Mohammedanism. The British government of Bombay, being desirous of suppressing the piracy that was carried on in the Gulf, made common cause with the Imaum against his enemies; and the result was, that the pirates were subdued in 1820, and the Arabs in 1822. Being thus in secure possession of his dominions at home, the Imaum turned his attention to his more distant possessions; but those who lived on the mainland refused to submit to his authority, and retired from the coast when he attempted to reduce them to subjection; so that all his dependencies, with the exception of the islands of Mombas and Zanzibar, are now merely nominally subject to his authority. No prince in the East is more highly esteemed than the Imaum of Muscat. The liberality of his government, and the protection and toleration which he affords to merchants of all nations and of all religions, have induced very many from different countries to settle in his capital. He has a considerable fleet, which is chiefly employed in commerce. He continues in alliance with the British government, and a British consul resides at Muscat. Under the sway of the Imaum the country is rapidly rising in wealth, commerce, and civilization. Pop. of Muscat, together with Matarah, variously estimated from 25,000 to 60,000.

MUSCULUS, WOLFGANG, a German theologian, was born of poor parents at Dieuze in France in 1497. He entered the Benedictine abbey of Lutzelsheim at the age of fifteen, and was soon afterwards ordained priest. Chancing, however, to meet with the writings of Luther, he became a Protestant, threw off the gown in 1527, and married. Danger and poverty now assailed him; and it was not until he had been compelled to skulk from place to place, and to earn a scanty pittance by the labour of his hands, that he was appointed minister of Augsburg in 1531. During the next seventeen years, the time not devoted to his pastoral duties was occupied in defending the doctrines of the Reformation against the Anabaptists and the Papists, and in studying Greek and the oriental languages. He left Augsburg in 1548, and wandered through Switzerland, with his wife and eight children, for some time afterwards. At length he was appointed to the chair of theology at Berne. He held this post till his death in 1563. The works of Musculus contain, among others, *Commentarii in Genesim*, fol., Basle, 1557; *Commentarii in Matthæum*, fol., Basle, 1541; and *Loci Communes*, Basle, 1554.

MUSES, *THE*, were the inspirers of poets, and the patron goddesses of arts and sciences. Their number is given differently by different authors. According to Pau-

Museum.

sanias they are three—Melete, *Thought*; Mneme, *Memory*; and Aœde, *Song*. In Cicero there are four mentioned—Thelxinoë, *The Heart-delighting*; Arche, *Beginning*; Aœde; and Melete. Their genealogy is also disputed. They are variously represented by different writers as the daughters of Cœlum and Terra, of Pierus and Antiope, and of Jupiter and Minerva. But the prevailing notion is, that the Muses are nine in number, and that they were the offspring of Jupiter and Mnemosyne, Queen of Eleutheræ. They were born in Pieria, at the foot of Mount Olympus, and were called Clio, Euterpe, Thalia, Melpomene, Terpsichore, Erato, Polymnia, Urania, and Calliope. Their nurse was Eupheme; and they are said to have been educated by Harmonia in Attica. According to Hesiod, they usually dwelt on Mount Helicon. There they danced round the altar of Saturn, and bathed in the waters of Permessus, Hippocrene, and Olmeius. When the night came on, they set out on the discharge of their duties, robed in clouds, and chanting the praises of the gods as they floated through the air. Descending upon the earth, they visited those mortals who were the special objects of their care. They infused dignity and power into the words of rulers, and filled the souls of poets with light and harmony. By their presence every tormenting care was allayed. At times they dwelt in a magnificent palace on the summit of Olympus. There they stood in the presence of Jupiter, telling the secrets of the past, present, and future, or warbling festive songs at the banquets of the immortals.

The worship of the Muses began around their birthplace in Pieria. Thence it was transferred into Bœotia, and in course of time it became firmly established in that district. A temple was erected to "The Nine" at Thespiæ. The neighbouring Mount Helicon, with its wells of Aganippe and Hippocrene, was consecrated to them, and became the site of their sanctuaries and grottoes. From Bœotia the adoration of the Muses gradually spread through the rest of Greece. It was established in Parnassus by the erection of a temple, and by the consecration of the Castalian spring and of the entire mountain. A sanctuary was erected for its observance in the Academy at Athens. In course of time it was transferred to Italy. Poets and musicians were the principal votaries of the Muses, and on that account were sometimes called their sons. Thus ancient writers say that Hyacinthus sprung from Clio, Rhesus from Euterpe, the Corybantes from Thalia, and the Sirens from Melpomene. Yet it sometimes happened that those who had been the worshippers of the Muses became their rivals in the art of music. In such a rivalry the Sirens failed, and were punished with the loss of their wings. Thamyris hazarded a similar competition, and was smitten with blindness.

From being indiscriminately the patronesses of song, the Muses latterly came to be severally regarded as presiding over particular kinds of poetry and particular arts and sciences. (For an account of their distinctive offices, see the names of each.)

MUSEUM, a name originally applied to a part of the famous palace of Alexandria, on account of its being set apart for the worship of the Muses and the study of the sciences. Here were lodged and entertained the men of learning, who had each a handsome revenue. Its foundation is attributed to Ptolemy Philadelphus, B.C. 280, who here placed his library. The word *museum* is now applied to any place set apart as a repository for things which have an immediate relation to the arts. The most famous institutions in England bearing this name are those of Oxford, founded in 1679, and the British Museum, founded in 1753. (See LONDON, and LIBRARIES.) Galleries of paintings are likewise included under the term museum in Italy and France. Such are the Vatican, the Louvre, &c.

MUSIC.

Music.
Introduc-
tion.

WITHIN the limits necessarily prescribed to this article, it is impossible to do more than touch upon a few points belonging to the subject. A complete treatise upon the theory and practice of music, according to the received doctrines, would contain about six thousand articles, and would fill several volumes. In writing this article, we have frequently availed ourselves of materials offered by the best and latest musical authorities. When so many works have been published by skilful professional musicians upon their art, we have not the presumption to suppose that we can add much that is new; more especially as we have no new theory to propose, and to maintain with Quixotic zeal and recklessness. Whenever we differ from authorities generally followed, we express our dissent, and give our reasons for it. Our main purpose is to direct attention to some useful musical objects, hitherto in general too much overlooked; to point out some errors in the theory and practice of music; and to show the utter uselessness of pursuing the old routine of building up false theories of music, and spending years in the vain study of what is called thorough bass, and is even still considered, by too many persons, as comprehending the whole art and science of music. To attempt to make any one a composer of music by means only of dry treatises upon intervals and chords, is just as absurd as to attempt to make a poet by means of Bysshe's Art of Poetry, or other books of the kind. Genius and observation, and a careful study of the best models, are really the only things that can ever make a good poet, or a good painter, or a good composer of music. The aid of a skilful master will be of great importance, if he is not wrapped up in a theory. In the absence of a master, two or three of the best modern treatises, such as Reicha's and Cherubini's, may help the student to understand the construction of those models of composition which he ought to have constantly before him. We suppose the reader to understand musical notation, and to be able to sing, or to play upon some musical instrument. If this should be the organ, or piano-forte, so much the better for his more easy attainment of a knowledge of harmony; although he must always remember that both these instruments are *out of tune*, and do not produce perfect intervals or perfect harmony. If the student of musical composition would acquire a real dominion over the materials of his art, he must not trust entirely to his organ or piano-forte. He must learn to read, in silence, any piece of music in score (in partition), and to hear, "in his mind's ear," the effect of the whole; and he must learn to compose in silence, and without the aid of any instrument. All great composers have acquired these powers. This seems, to the vulgar musician, impossible. To mention only one instance of such powers among living artists; Cherubini composes all his music with the aid of no other instruments but pen, ink, and paper. We have seen him at work. An accomplished composer is able to form in his mind, with no aid from any instrument, the whole plan and details of a complicated piece of harmony, before he writes a note of it. In his "mind's eye" he *sees* the whole score; in his "mind's ear" he *hears* the effect which the piece would produce if performed. Until the student acquires this power of abstraction, he must consider himself as only on a par with those every-day musicians whom the "fatal facilities" of the organ or piano-forte raise into the ephemeral class of pseudo-composers.

Some persons consider music as a frivolous and useless art. They do not feel nor understand music, and they are

not to be blamed for this when nature has denied them a musical ear, any more than a blind man is to be blamed for not admiring painting or sculpture, or a blind and deaf man for not admiring poetry. But really, when musical compositions are frivolous and useless, the fault is in the artist, not in the art. If men choose to write bad poetry, to paint bad pictures, to chisel bad sculptures, this can never prove that poetry, painting, and sculpture, are frivolous and useless arts. Every one of the fine arts may be rendered frivolous and useless by misapplication of its means; nay, some of them may be made highly dangerous and mischievous, as has often happened. No doubt all the fine arts may be considered in one point of view as *superfluous* things, not at all contributing to the *necessaries* of human existence. Food, clothing, fire, and shelter, are really all that man's mere animal existence requires to keep him alive. But if poetry and music, and painting and sculpture, cannot till the earth, nor build hovels, nor make clothing, nor kindle coal-fires, they can at least add ornaments to the structure of civilized society, and contribute to the innocent pleasures and happiness of man's transitory life. And it seems to be proved by experience, that the cultivation of these arts, how unimportant soever they may be to mere animal existence, has always tended to divert the attention of mankind from the sole indulgence of their animal appetites, and of their more dangerous passions. If so, it would not be wise to deprive man of such sources of innocent and pleasing occupation, or rather relaxation, and to reduce him to the merely animal state of the savage, who enjoys and admires nothing beyond his animal comforts, and his murderous triumphs over his rivals or his enemies.

Many persons are so constituted, or so trained, as to have no relish for poetry, or painting, or music. So much the worse for them, perhaps, since their want of feeling or imagination deprives them of sources of innocent pleasure open to others. If a mere mathematician should be dissatisfied with the works of a great poet, because these works *prove* nothing mathematically, a lover of poetry must not take offence at the mathematician. The lover of poetry, perhaps himself a poet, may be totally insensible to the beauties of the most profound mathematical reasonings, or the finest musical compositions. This often happens. But it rarely happens that the real lover of music is not also a lover of poetry and of painting. We have known men high in the literary and scientific world, upon whom the best music produced no other impression than that of an agreeable or a disagreeable noise. But this never made us respect them the less for their own *peculiar* powers of feeling and thinking. They were not so organized as to feel and think as we did. That was all. The wiser and more philosophical plan is, not to be angry with any of our fellow-creatures for not feeling and admiring as we do; but to regret that they cannot feel and admire with us, because such communion of feeling and admiration would serve to draw those persons closer to us in human fellowship. To call a man a blockhead, because he does not, or cannot, feel and think in every thing exactly like ourselves, is merely to be at once ill natured, uncharitable, and unphilosophical. It is, "*not to know ourselves.*" *Non omnia possumus omnes.* We find no fault with men who *cannot* perceive the beauties of music. We find fault with the perversions of an art which we ourselves feel to be a fine and expressive one, too often deformed and perverted.

Music.

Music.
Definition
of music.

Most treatises on this subject begin with a definition of music. To persons who already understand music thoroughly, any attempt at such a definition is unnecessary. They have already formed their own ideas of music as an art. To persons ignorant of music, any such definition is quite unintelligible. The extent, the complexity, and the mutability of the art, render all such definitions imperfect and objectionable. The best way in this, as in all others of the fine arts, is to leave the student to form his own definition, after he has thoroughly studied the art. We follow this plan.

In some of the latest and best works on music, we find a definition of it attempted in this manner: "The art of expressing an agreeable play of feelings by means of sounds." But music often expresses the most painful and tragical feelings. Another is, "The art of expressing determinate feelings by means of regulated sounds." And then follows a long description of the nature of all the various branches of music; which is just tantamount to a confession that the definition is unintelligible and useless without the lengthy description.

Leibnitz had a strange metaphysical notion of music, which he thus expressed: "*Musica est exercitium arithmeticae occultum nescientis se numerare animi; multa enim facit in perceptionibus confusis seu insensibilibus, quæ distinctâ apperceptione notare nequit. Errant enim, qui nihil in anima fieri putant, cujus ipsa non sit conscia. Anima igitur etsi se numerare non sentiat, sentit tamen hujus numerationis insensibilis effectum, seu voluptatem in consonantiis, molestiam in dissonantiis inde resultantem. Ex multis enim congruentiis insensibilibus oritur voluptas,*" &c. Descartes entertained similar notions; and Euler, in his *Tentamen Novae Theoriae Musicae*, assures us that the ear is pleasingly or unpleasingly affected by musical intervals, according to its perception of the simplicity or of the complexity of their ratios of vibration. His measures of these ratios do not agree with practice. But the absurdity consists in supposing such an auricular arithmetic, by which the ear judges of the ratios of intervals. Does the milk-maid calculate the ratios of the intervals in her untutored song, and take pleasure in it, or the reverse, according to her perception of their simplicity or complexity? In Italy we may hear persons who cannot read music, singing very agreeably in two, or three, or four parts, in harmony. Do such persons know any thing of the harmonic ratios of the sounds they combine together in this way? They have no more idea that even an octave is in the ratio of 1:2, than they have of the distance between the earth and the moon. Similar false applications of mathematics have tended greatly to produce that mysterious obscurity which has hitherto been artificially thrown over the beautiful and inviting regions of musical melody and harmony. There, genius and perseverance have culled the sweetest flowers; while mathematical investigations have, as yet, only groped among the soil from which these blossoms sprang.

Theories
of music.

The state of our knowledge of acoustics, one of the most subtle and difficult of sciences, is still too incomplete to permit of the formation of a perfect theory of music, even were music, as a fine art, entirely dependent upon the physico-mathematical science of acoustics, which it is not. Of late years, however, the beautiful experiments of Dr Chladni, M. Oërsted, Monsieur Savart, Professor Faraday, and Professor C. Wheatstone, have thrown much light upon some of the obscure parts of acoustics.

In another work, we have expressed ourselves in the following terms regarding proposed theories of music. "The mischievous effects of false principles have been experienced in every branch of physical science. The blind rashness of premature generalization has operated with as great absurdity in music as in any other branch of

human knowledge. While music was in its infancy, and while the observations and experiments which had been made respecting it were confined within limits by much too narrow to permit the formation of just and comprehensive general principles, musicians, both practical and speculative, misled by a false philosophy, and by erroneous ideas of simplicity, attempted to establish one single principle as the sole basis of musical harmony and composition. Confounding together the essentially distinct methods proper to physical and to mathematical science, they seized upon a particular phenomenon belonging to acoustics, and endeavoured to torture it into a principle which might apply to, and explain, the whole phenomena belonging to musical composition. From a particular fact, which had no necessary connection with musical composition, they attempted, with some ingenuity, and with much sophistry and ineffectual labour, to deduce the whole system of that art; while they were not aware either of the imperfection and incompleteness of the system which then existed, or of the improper method of induction which they had adopted. They employed the synthetical method of induction proper to mathematics, instead of the analytical method of induction, which is the true guide to physical investigation. In mathematics, we make discoveries by reasoning from definitions, axioms, and postulates; in other words, by reasoning from generals to particulars; but in physics, we extend our views and consolidate our knowledge by the opposite method of reasoning from particulars to generals. In physical science, when our observations and experiments have been sufficiently numerous and extensive, we may then, but not till then, establish general laws, or first principles, and reason from these synthetically; but if, on the contrary, the facts from which we generalize have been gathered from a narrow and unenlightened survey of the field of physical science, we shall almost inevitably draw false conclusions, and form principles which involve error and absurdity in relative proportion to the obscurity and contraction belonging to our investigation of particulars.

"It was long ago observed, that a musical string, or wire, capable of rendering a grave and powerful sound when thrown into a state of vibration, produced, in that state, not only a *principal* sound, corresponding to its length, tension, thickness, &c., but also two audible, concomitant, and accessory sounds, related to the *principal* sound by the intervals of a twelfth, or double (replicate) fifth, and seventeenth major, or second replicate major third. For example, the fourth string, or largest string of the violoncello, when strongly vibrating, may produce these accessory sounds, or *harmonics*; which, although feeble in comparison with the principal sound, may, however, be heard by a delicate and attentive musical ear.

"Upon this acoustical phenomenon, Rameau, a French musician, attempted to found his theory of harmony. We shall afterwards quote the opinions of some of the highest authorities in Europe upon this theory, and also upon that of Tartini, to which we now proceed.

"Tartini, in his *Trattato di Musica*, published at Padua in 1754, informs us, that if two sustained sounds (forming, for example, a third or a fifth) are produced at once from two violins, two trumpets, &c. the result will be the generation of a harmonic third sound, distinctly perceivable by the ear. This phenomenon was observed by Rameau in 1753. Tartini seems to have mistaken the pitch of the third sound, or grave harmonic, produced in this experiment, since M. Serre of Geneva, in his *Principles of Harmony*, tells us that the grave harmonic sounds produced by major and minor thirds are each an octave lower than those mentioned by Tartini. This phenomenon gave rise to Tartini's theory of harmony. We now make the quotations which we promised. The first is from the works of

Music.

Music.

the late Professor Robison, whose authority, on such a point, is of indubitable weight. He is writing of Rameau's theory. 'Rameau has made this,' the generation of acute harmonics, 'the foundation of his system of music, asserting that the pleasure of harmony results from the successful imitation of this harmony of nature. But a little logic should convince these theorists that they must be mistaken. A little mathematics, too, or mechanics, would have convinced them. His theory is a very *forced* accommodation of this principle to the practice of musicians and taste of the public.' Speaking further of Rameau's theory, he says, 'It is a mere whim, proceeding on a false assumption, namely, that a musical sound is essentially accompanied by its octave, twelfth, and seventeenth, *in alto*. This is not true, though such accompaniment be very frequent, &c. Are these acute harmonics musical sounds or not? He surely will not deny this. Therefore they too are essentially accompanied by *their* harmonics, and this absolutely and necessarily *ad infinitum*.' Of Tartini's theory he says, 'Tartini prized this observation,' the generation of grave harmonics, 'as a most important discovery, and considered it as affording a foundation for the whole science of music.' After some farther remarks, he adds, 'The system of harmonious composition which Tartini has, with wonderful labour and address, founded on it, has, therefore, no solidity.'

"Dr Chladni, in his celebrated work *Traité d'Acoustique*, expresses himself as follows regarding the theories which we have just mentioned: 'It is not conformable to nature to desire, like many authors, to derive all harmony from the vibrations of a string, and especially from the co-existence of several sounds with the fundamental sound. A string is *only one* species of sonorous body.'

"'In many other sonorous bodies the general laws of vibrations, which were not known, are differently modified, consequently the laws of one sonorous body cannot be applied to that which ought to be common to all. A monochord cannot serve to establish the principles of harmony, but only to give an idea of the effect of ratios.'.....'Many authors have regarded the co-existence of sounds comprised in the natural series of numbers (which, according to true principles, is nothing but a particular phenomenon) as an essential difference between a distinct sound and a noise. They have taken this quality for the basis of all harmony, believing that an interval is consonant, *because* the acute sound may be heard along with the fundamental sound. They do not know that, if more than one sound is heard at the same time, this is nothing more than a consequence of the existence of many species of vibrations; that in many sonorous bodies the series of possible sounds is very different from the natural series of numbers; and that we may produce each manner of vibrations, where there are nodes, without any mixture of other sounds, by touching the nodal points, or lines, which ought to be in motion in other manners of vibrating.

"'According to their principles, the perfect minor chord—if one does not make use of sophisms—would not be consonant; and, on the bell of the harmonica, the ninth (4:9) would be the first consonance, since it is the first sound which can mingle itself with the fundamental sound, &c. Daniel Bernouilli and Lagrange have sufficiently refuted these false principles.'

"With respect to Tartini's theory in particular, he says, 'Tartini pretended that this third sound was more acute by an octave than it really is. He regarded this phenomenon, combined with the pretended co-existence of the series of sounds 1, 2, 3, 4, 5, &c. in each fundamental sound, as the basis of harmony. Mr Mercadier de Belestas has very well refuted some false assertions of Tartini, in his *Système de Musique*, Paris, 1776.'

"Choron, in his work upon composition, says, 'It has

been attempted to deduce the laws of succession from the multiple resonance, or from the sub-multiple resonance. Tartini had hardly discovered this last phenomenon, when he hastened, in order to satisfy the taste of his time, to rear up upon it a system, which he gave to the world in a very unintelligible work. J. J. Rousseau, who was almost equally a stranger to geometry and to the science of composition, produced, without having even comprehended it, a very imperfect analysis of it (Tartini's system) in his shapeless dictionary, and exalted it to the utmost of his power, for the pleasure of mortifying Rameau, with whom he had some quarrel.

"'With the phenomenon of the multiple resonance, of which he had considered no more than the three first terms, Rameau had propped up his system of the fundamental bass. Without entering more into detail, I shall remark, that this phenomenon has no connection with the laws of harmony. That if one absolutely would apply it to them, it would be necessary, *first*, in order to be consistent, to suppose, at least implicitly, that the sounds of the system are those of the series of aliquots: first absurdity. *Second*, That all the notes of the bass ought to be accompanied by all their aliquots, moving in a parallel manner with each other: second absurdity. Every other consequence is illegitimate, and tends, not to give a foundation in nature to the rules of harmony, but to reconcile, as one best can, the phenomena with the rules of harmony, which is a very indifferent matter.'

In 1753, M. Serre, a miniature painter at Geneva, published his *Essais sur les Principes de l'Harmonie*. He assumed three essential fundamentals in the scale; the tonic, the fifth, and the fourth. He described the nature and use of what he termed *diacromatic* intervals, or slides necessary to perfect intonation in various modulations; and he laid down as a principle, that it depended upon the nature of the intervals of a chord whether that chord should have *one* or *two*, or even *three* fundamentals. These opinions of M. Serre's have been of late years, and with some modifications, reproduced as new. In some works recently published, we have observed an analogy pointed out, as new, between the harmonics above mentioned and the curious phenomena of complementary colours. In Blackwood's Edinburgh Magazine for February 1823 (pp. 159-162), will be found a letter of ours in Italian, in which this analogy is particularly noticed, and a short description of some of the phenomena given. In the same letter there are some remarks upon the analogy between the harmonic series 1, 3, 5, 7, &c. and the progression of numbers 1, 3, 5, 7, ascribed by Newton to the squares of the diameters of the coloured circles produced by him on applying to the plane side of a plano-convex lens one of the convex sides of a double convex lens.

A strange error has long prevailed regarding the co-existent vibrations of a musical string. The *total* vibration which gives the gravest sound of the string, can by no means *co-exist* with the vibrations of the aliquot parts of the same string. The thing is physically impossible, as could be easily demonstrated. In fact, to assert that a vibrating string can move in a number of *different* and *opposite* directions at the same instant of time, is as absurd as to maintain that a man can run backwards and forwards, to the right and to the left, &c. all at the same moment. The following diagrams represent the three primary curves of the harmonic series 1, 2, 3.

Music.

The co-existence of all these curves is a *physical impossibility*. For how can ACB coincide with AdeB, or with AfghB? It is needless to go farther. There may be many *co-existent* vibrations of traction and torsion in the string, but not any *co-existent* vibrations in directions quite opposite to each other.

The musical treatises of Choron, Catel, and Momigny, &c. among the French, and of Reicha and others among the Germans, are still too much tinctured with peculiar and arbitrary theories and systems, for which there are no sufficient grounds in either acoustics or æsthetics. By this last term the Germans have long chosen to designate, not very appropriately, the theory of taste in the fine arts. It is indeed impossible, by any purely mechanical and mathematical theories, or even by any metaphysical ones, to explain all the varieties of human sensations, affections, passions, that enter into our perceptions of beauty, sublimity, &c. in poetry, painting, or music. It cannot be too often repeated, that all the *rules* laid down by theorists for the construction of works belonging to the fine arts, are drawn from models of art previously in existence, and relate merely to the mechanical portions of these arts.

Had the rigid rules formed for (and from) the ancient Greek drama been always adhered to, we should never have possessed Shakspeare's plays. The magnificent musical works of Haydn, Mozart, and Beethoven, not to speak of many other great German and Italian composers, were not produced by blind adherence to old rules of art, but by an enlightened view of things, far beyond what the authors of these rules contemplated. Böhle has remarked, that the mechanical rules laid down in treatises on the fine arts may be compared to telescopes, which assist the vision of those persons who already see. A remarkable instance of this is found in the case of Beethoven, who happened to be placed under a master destitute of genius for melody; but a profound harmonist, and a learned writer of fugues and canons, &c. Under this man, Beethoven laboured most industriously, and went through the whole drudgery of thorough bass, and all the rigid ancient rules of composition; but evidently with frequent misgivings as to the general truth and application of what was taught to him. But the result was, that these lessons and *rules* served him as a "telescope," to enable him to perceive a wide field of composition far beyond them all. In short, he was a man of first-rate musical genius, and therefore by nature a great melodist; and, fortunately for the world, his injudicious training *could* not extinguish his passionate feeling for melody, and his charming expression of it in his best works. In some of his works, especially among his last, we find unpleasing traces of the predominance of his early training over his native genius. But his latest works were composed when he had been for many years perfectly deaf.

The sense of hearing. Notwithstanding the laborious investigations of many eminent anatomists and physiologists, from Comparetti downwards to Magendie, the uses and functions of all the

various parts that compose the human ear are by no means well understood.

The perceptive powers of the ear differ considerably among mankind, especially as regards the perception of the various qualities and relations of musical sounds. In like manner, we find that the perceptions of form, proportion, colour, &c. are by no means always the same in every human eye. Perfection of the eye is requisite to the painter; perfection of the ear to the musician. Sometimes persons are found who cannot distinguish colours, or shades of colour, from each other. Perhaps more frequently instances are met with of persons whose perceptions of the differences between musical sounds are very imperfect. We have been informed that Mr Pond, the late astronomer royal, though a real lover of music, and capable of hearing distinctly sounds of a grave pitch, or of a middle pitch, was incapable of hearing very acute sounds, whether musical or not, which were perfectly audible to other persons; for example, the loud chirping of a number of crickets in a room, and the very piercing sound produced by turning round the ground-glass stopper of a bottle containing calomel. The stopper was turned round close to Mr Pond's ear without producing any sensation. All this clearly proved that Mr Pond's ear, however perfect in other respects, was incapable of conveying any perception of very acute sounds.

All vibrations sufficiently rapid and powerful to act upon the auditive organs produce the sensation of sound. To enable us to hear slow vibrations as well as more rapid ones, it would be necessary, according to Riccati, that the intensity of each simple vibration should be in proportion to its duration. For this reason, says Chladni, and on account of the different organization of each individual, and each kind of animal, there exist no absolute limits to the perceptibility of sounds.

The ear does not distinguish the very small differences of the exact ratios between sounds. Were it not for this illusion, music would have no existence. But this is not to make us seek the less for true intonation, wherever it can be obtained. Few persons are aware how great is the difference between the true intonations of a fine voice, or a violin, &c. and the false intonations of such instruments of fixed sounds as the organ, piano-forte, &c. Many singers, trained to the intonation of a piano-forte, have their ear and voice so misled that they can never afterwards learn to sing in tune. The famous Madame Mara condemned the use of the piano-forte in learning to sing. She said every singer ought to learn to play on the violin, in order to know what true intonation is.

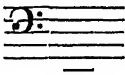

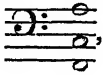

The different quality (*timbre*) of a musical sound and its articulations, says Chladni, are among the most remarkable objects of audition. They do not appear to depend on the manner of vibration, nor (or very little) upon the form of the sonorous body; but rather on the matter of the sonorous body, and that of the body by which it is rubbed or struck, as well as on the matter which propagates the sound. We have not the least idea of the nature of these different characters of sound, nor of their propagation.

The limits usually assigned to musical sounds, reckoning from grave to acute, or the contrary, are as follows:

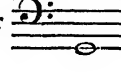

The lowest of these sounds will be such as is produced by an open organ-pipe of 32 feet in length, and the num-

Music. University, pointed out some useful applications of the logarithmic subdivision of the circumference of a pasteboard circle, fitted with a moveable concentric circle, &c. as described in his article TEMPERAMENT, in the present work. He adds: "Or a straight line may be so divided, and repeated thrice; then a sliding ruler, divided in the same manner, and applied to it, will answer the same purpose." We may remark, that these suggestions of Professor Robison have been employed in the construction of similar instruments, without any acknowledgment; and also, that Professor Robison's experiment, by applying a stop-cock to an organ-pipe, and producing various sounds from the regular and rapid opening and shutting of the stop-cock, bears great analogy to the syren instrument recently constructed by M. Cagniard de la Tour. Professor Robison, speaking of his stop-cock apparatus, says, "The intelligent reader will see here an opening made to great additions to practical music, and the means of producing musical sounds, of which we have at present scarcely any conception," &c. We have already mentioned, very briefly, how intervals are produced by the subdivisions of a sonorous string or wire, &c. or of the column of air in a wind-instrument, or in the glass tube before described.

If we suppose such a tube to produce, as its gravest sound, , its primary harmonics will be .

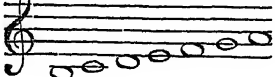

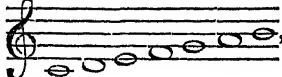

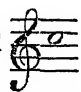

viz. octave, replicate of fifth, and replicate of third. Carrying the series farther, we shall have one similar to that already given in the table of harmonics. Supposing two other such tubes, the one having for its gravest sound

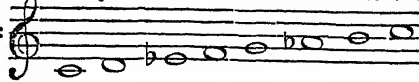

, and the other , the harmonics re-

sulting from these respectively will be , and , and so on, as in the case of the first.

By bringing closer together these dispersed primary har-

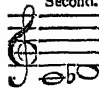

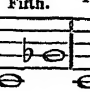

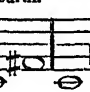

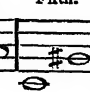

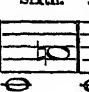

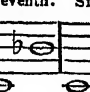

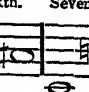

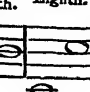

monics, by means of their octaves above or below, we shall obtain the following series of sounds:

 or 
and so on. If to the last of these series we add 

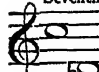

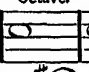

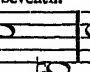

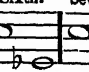

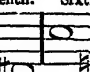

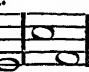

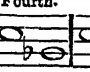

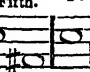

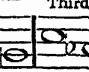

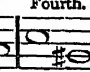

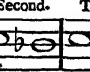

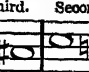

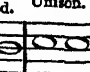

at the top, we shall have the major diatonic scale of C. By carrying farther the series of harmonic products of these three tubes, we shall obtain a number of other intervals (see the table), and among these the ones suitable to the scale of C minor: .

The subject of intervals has been involved in frightful confusion by the number and complexity of names introduced, and the contradictory statements of various writers upon music. We have no space to devote to the clearing up of this chaos; but we may remark, in general, that in this matter, as well as in many others connected with music, there is great need of a reformation in terminology. To glance at only three or four of the misnomers in daily use, without meddling with the more abstruse terms: the fifth diatonic sound of an ascending scale is called the *dominant* of the scale, which signifies the *ruling* or *governing* sound; while, in fact, the tonic, or key-note, and no other, is the chief and ruling sound of the scale, the sound from which, as a common centre, all the others of the scale may diverge, or to which they may converge, like the radii of a circle. This use of the term *dominant* seems to have arisen from the *predominance* of the fifth of the key in ancient church-chants. The term *subdominant* is improper, too, as applied to the diatonic fourth of a scale. The terms *double octave*, *double third*, *double fourth*, &c. are wrong as applied to intervals, because they *imply* that these intervals are *doubled* in the unison, while it is meant to express only the acuter or graver replicates of these intervals in the octave. The same with regard to *triple octave*, &c. When we read of *diminished* or *augmented unisons*, *false fifths*, *superfluous fifths*, *seconds*, &c. &c. we must regret the obscurity of such terms; but meantime we shall use the common terms as we find them, because to introduce new ones abruptly would only add to the confusion already existing.

Table of Intervals in general use.

Minor Flat Second.	Augmented Unison.	Major Second.	Minor Third.	Augmented Second.	Major Third.	Fourth.	Diminished or Flat Fifth.	Augmented Fourth.	Fifth.	Minor Sixth.	Augmented Fifth.	Major Sixth.	Minor Seventh.	Augmented Sixth.	Major Seventh.	Eighth.
																

Inversions of the above Intervals.

Major Seventh.	Diminished Octave.	Minor Seventh.	Major Sixth.	Diminished Seventh.	Minor Sixth.	Fifth.	Augmented Fourth.	Diminished Fifth.	Fourth.	Major Third.	Diminished Fourth.	Minor Third.	Major Second.	Diminished Third.	Minor Second.	Unison.
																

Inversion of an interval takes place when the graver sound is carried an octave higher, or the acuter an octave lower. The effect of inversion of intervals may be represented by the following two rows of figures, where it will be seen that 1 or unison, becomes 8 or octave; 2, or second, becomes 7 or seventh, and so on.

1	2	3	4	5	6	7	8
8	7	6	5	4	3	2	1

By looking at the above table of intervals, and their in-

versions, we perceive that *minor* intervals inverted become *major*, and *major*, *minor*; *diminished* intervals become *augmented*, and *augmented*, *diminished*. We have placed D \flat before C \sharp , and E \flat before D \sharp , and so on; because, contrary to the common opinion, the D \flat in the above series is a graver sound than the C \sharp , and the E \flat than the D \sharp , and so of the others. This is not easily understood by a mere player on the organ or piano-forte, but can be exemplified by any accomplished singer or violinist.

In writing for voices, especially in the strict or serious

Music. style, many of these intervals are not used. The following are generally prohibited in that style: Augmented second, diminished fourth, augmented fourth, diminished fifth, augmented fifth, major sixth, diminished seventh, minor seventh, major seventh, augmented third.

Musical scales, modes, keys.

Scale is the more comprehensive of these terms, since all appreciable musical sounds between the extremes of grave and acute form the general scale or system of sounds employed in melody and harmony. A *mode* is a certain arrangement of tones and semitones, &c. between a given

sound and its octave above or below. *Key* properly signifies a character employed at the beginning of the staff, to fix the names of the notes; but it has long been used as nearly synonymous with scale or mode, since these terms are often employed the one for the other. What is called the *key-note*, or *tonic*, is the principal sound of a mode, or that from which we begin to reckon its degrees upwards or downwards. Suppose we take the note C as *tonic*, or *key-note*. The arrangement of notes No. 1 will form the *mode* or *key* of C major, and the arrangement of No. 2 the *mode* or *key* of C minor.

Music.

Both these are called *Diatonic* scales, although they are not strictly such, since they contain other intervals besides tones. The chromatic scales formed from these consist of a semitonic (or so-called semitonic) series between the key-note and its octave above or below, ascending or descending. These two modes, major and minor, and their respective chromatic scales, may be considered as the types or representatives of all other major and minor modes and chromatic scales. No. 3 and No. 4 are two forms of the major and minor mode not generally adverted to, but which are very effective when skilfully used, as, for example, by Haydn in the andantino in C minor of his symphony in E flat. As an octave series or scale may be formed anywhere within the limits of appreciable musical sounds, we thus obtain a variety of scales, diatonic and chromatic, all of which, however, are to be considered as only so many fragmentary formulæ, comprehended within, and belonging to the *whole series* of the general system. Thus we shall have the modes or scales of C flat, C sharp, major and minor; D major and minor, D flat and D sharp, major and minor, and so on with E, F, G, A, B, and their chromatic alterations, flat or sharp. The term *key* is usually applied to these. Thus we speak of the *key* of C major, of C minor, of C sharp major or minor, and so on. As concert-pitch is not one and the same in all countries, keys of the same name do not everywhere correspond exactly. The production of what is called the sharp series of keys arises from a regular succession of perfect fifths taken in ascending, or fourths in descending, beginning with C for the major ones, or A for the minor ones. Thus the first step of a 5th ascending from C brings us to G as a new key-note. G major, with one # at the clef. The first step of a 5th ascending from A brings us to E as a new key-note E minor, with one # at the clef. A 5th, again, ascending from G brings us to D major with two sharps at the clef; and a 5th ascending from E brings us to B minor, also with two sharps at the clef; and so on progressively with the major keys of A, E, B, with 3, 4, 5 sharps at the clef, till at last, at the twelfth 5th from C, we reach B sharp, which, when brought down by octaves towards the original C, will be found not to correspond with that C in unison or octave, but to be too sharp. The same thing will occur after a similar series of twelve perfect 5ths from A, as tonic of A minor, up to G double sharp, which last will not be in unison or octave with the original A, but will be too sharp in the same proportion as the other extreme of the series of twelve ascending 5ths from C to B sharp. We may mention here, that composers seldom go beyond the keys of F# or C# major or minor, in

their notation of a piece of music, on account of the multiplicity of sharps and double sharps in the subsequent keys of G#, D#, A#, E#, B#, and the difficulty of reading these, and of playing in tune in such keys upon musical instruments even of the most perfect kind.

What is called the flat series of keys, arises from a succession of perfect 5ths, the converse of the former. That is to say, when, beginning with C, or with A, for the major or for the minor series, each key-note, in regular succession, is a 5th in descending below, or a 4th in ascending above the key-note immediately preceding. Thus, from C to F in descending, F major with one flat at the clef; from this F to Bb in descending, Bb major with two flats at the clef; and so on with Eb, Ab, Db, major, and with 3, 4, 5 flats, &c. at the clef. Then, again, the minor flat series, beginning from A as tonic of minor, D minor with one flat at the clef; from D tonic to G tonic of G minor, with two flats at the clef; and so on with C minor, F minor, B flat minor, &c. with 3, 4, 5 flats, &c. at the clef. We may here remark, that what is commonly called the relative minor key of a major key, has its tonic at the interval of a minor third below the tonic of that major key, and bears at the clef the same number of sharps or of flats. Thus the relative minor of C is A, without any sharps or flats at the clef; the relative minor of G is E, with one sharp at the clef; and so on with D major and B minor, A major and F sharp minor, &c. with 2, 3 sharps, &c. The same kind of relation occurs in the flat series of relative major and minor keys. Thus C major, A minor; F major, D minor; each of the latter two with one flat at the clef; B flat major, G minor, each with two flats at the clef; and so on with the rest, 3 flats, 4 flats, &c. The remoter flat keys beyond D flat are rarely used, for reasons similar to those assigned for the infrequent use of sharp keys beyond C sharp. To render more intelligible what has been said regarding the production of the sharp and the flat series of keys, we subjoin the following explanations. Suppose a musical string to render a sound equal to the lowest C of the violoncello, and to be numerically represented by 1. If this string be divided into three equal parts, any one of these parts will (tension and other circumstances remaining the same) render a sound equal to the first octave of the 5th above that C, and will be

expressed by $\frac{1}{3}$. Two of these parts taken together will render the 5th above that C, and such 5th will be expressed by $\frac{2}{3}$, and will be equivalent to the lowest G of

Music. the violoncello. Taking, again, the length of the string represented by $\frac{2}{3}$, and dividing it into three equal parts, two of these parts will render a sound equivalent to D of second open string of violoncello, and this D will be expressed by $\frac{2^2}{3^2}$. By proceeding in the same manner, we

shall obtain the series represented in the following diagram. With regard to the numerical expressions placed under the 5ths, it will be remarked, that at each successive 5th, the exponent of the number 3 increases by one, while that of the number 2 sometimes increases by one, sometimes by two, according as the new term is in the 5th above, or in the 4th below, the preceding one.

Music.

<div> <div>1</div> <div>$\frac{1}{3}$</div> <div>$\frac{2}{3}$</div> <div>$\frac{2}{3^2}$</div> <div>$\frac{2^2}{3^2}$</div> <div>$\frac{2^3}{3^2}$</div> <div>$\frac{2^4}{3^3}$</div> <div>$\frac{2^6}{3^4}$</div> <div>$\frac{2^7}{3^5}$</div> <div>$\frac{2^9}{3^6}$</div> <div>$\frac{2^{10}}{3^7}$</div> <div>$\frac{2^{11}}{3^7}$</div> <div>$\frac{2^{12}}{3^8}$</div> <div>$\frac{2^{14}}{3^9}$</div> <div>$\frac{2^{15}}{3^{10}}$</div> <div>$\frac{2^{17}}{3^{11}}$</div> <div>$\frac{2^{18}}{3^{12}}$</div> <div>$\frac{2^{19}}{3^{12}}$</div> </div>

We shall find that the B \sharp , the twelfth 5th of this series, will not be in unison with C $\frac{1}{2}$, the octave above the original

C1, but will be more acute than that C $\frac{1}{2}$. If we suppose

the whole string C1 divided into a number of parts equal to $2 \times 531,541$, the B \sharp in question will have 524,288 of these, while the C $\frac{1}{2}$ will have 531,541; and therefore the

B \sharp will be the acuter sound of the two. In reversing the process above described, that is to say, in reckoning a series of 5ths from acute to grave, the numerical expression of the 5th will be $\frac{3}{2}$. If, then, we set out from the C re-

presented by $\frac{1}{2}$, and carry on, from acute to grave, a series of operations similar to the former, we shall obtain the following expressions for the flat series of keys by descending 5ths.

$\frac{1}{2}$	$\frac{3}{2^2}$	$\frac{3^2}{2^4}$	$\frac{3^3}{2^5}$	$\frac{3^4}{2^7}$	$\frac{3^5}{2^8}$	$\frac{3^5}{2^{10}}$	$\frac{3^7}{2^{12}}$	$\frac{3^8}{2^{13}}$	$\frac{3^9}{2^{15}}$	$\frac{3^{10}}{2^{16}}$	$\frac{3^{11}}{2^{18}}$	$\frac{3^{12}}{2^{19}}$

The D $\flat\flat$, the twelfth 5th from C $\frac{1}{2}$, will be found to be a graver sound than C1, the octave below that C $\frac{1}{2}$; for, supposing the whole string = C1 divided into 524,288 equal parts, the D $\flat\flat$ would require 531,541 of these parts,

which exceeds the whole length of the string, and would therefore produce a graver sound than C1. The following diagram of the scales by 5ths ascending (sharp series), and by 5ths descending (flat series), will show the relative differences in pitch between the sounds of the one series and of the other.

Scale of Ascending Fifths.

C	G	D	A	E	B	F \sharp	C \sharp	G \sharp	D \sharp	A \sharp	E \sharp	B \sharp
$\frac{2^0}{3^0}$	$\frac{2^1}{3^1}$	$\frac{2^3}{3^2}$	$\frac{2^4}{3^3}$	$\frac{2^6}{3^4}$	$\frac{2^7}{3^5}$	$\frac{2^9}{3^6}$	$\frac{2^{11}}{3^7}$	$\frac{2^{12}}{3^8}$	$\frac{2^{14}}{3^9}$	$\frac{2^{15}}{3^{10}}$	$\frac{2^{17}}{3^{11}}$	$\frac{2^{18}}{3^{12}}$

Scale of Descending Fifths.

D $\flat\flat$	A $\flat\flat$	F $\flat\flat$	B $\flat\flat$	F \flat	C \flat	G \flat	D \flat	A \flat	E \flat	B \flat	F	C
$\frac{3^{12}}{2^{19}}$	$\frac{3^{11}}{2^{18}}$	$\frac{3^{10}}{2^{16}}$	$\frac{3^9}{2^{15}}$	$\frac{3^8}{2^{13}}$	$\frac{3^7}{2^{12}}$	$\frac{3^6}{2^{10}}$	$\frac{3^5}{2^8}$	$\frac{3^4}{2^7}$	$\frac{3^3}{2^5}$	$\frac{3^2}{2^4}$	$\frac{3^1}{2^2}$	$\frac{3^0}{2^1}$

If we compare with each other the corresponding terms of these two scales or series, we perceive that the sounds of the sharp series are more acute than those which correspond with them in the flat series, because the strings which produce the latter surpass the others in length by the difference between 524,288 and 531,541, = 7253. A slight consideration of these processes, and their results, will show the necessity of what is called *temperament* upon such an instrument as the organ, the piano-forte, &c. By it the fifths are rendered a little false, in order to obtain all the octaves true.

What are called the ancient ecclesiastical scales or modes, being, in reality, nothing but certain conventional scales or modifications of the common major and minor scales, and differing from these in nothing but the disposition of their semitones, it is not necessary here to notice them very particularly. The four most ancient of these were the Dorian, the Phrygian, the Lydian, and the Myxo-Lydian. The first of these was equivalent to the series d, e, f, g, a, b, c, d ; the second to e, f, g, a, b, c, d, e ; the third to f, g, a, b, c, d, e, f ; and the fourth to g, a, b, c, d, e, f, g . The dif-

Music. ferent positions of the semitones is indicated by the curved line ~. The reader will find a full explanation of all the ecclesiastical modes, authentic and plagal, in the first part of the first volume of Padre Martini's *Saggio di Contrappunto*. A good many years ago, a Frenchman, Blainville, pretended to have discovered a new scale or mode, which was really nothing more than the Phrygian mode above indicated. Reicha, in his volume of thirty-six fugues, proposed what he considered as a *new system* of scales, harmonies, and cadences, which he considered as *relative* to the usual major and minor scales, &c. These relative scales, however, were merely the Dorian and others above mentioned, with the addition of the series *a, b, c, d, e, f, g, a*. The relative cadences were those that might be used between the assumed dominant and tonic of such scales, there being no chromatic alteration made in the sounds of the scale. For example:

Reicha says, enthusiastically, "according to this system, we should have two primitive scales, a major and a minor, and five relative ones; and, by transposition, twelve primitive minor scales, and sixty relative scales; in all eighty-four scales, and as many cadences. What resources unknown till now!" We cannot join Reicha in this burst of enthusiasm. The formulæ of these scales and cadences are to be found in a great many old church chants, and even national melodies. We must not mistake these fragmentary formulæ for entire and peculiar scales, independent of the general system of musical sounds. Reicha adds, "It remains for philosophers and men of genius at a future period to deduce all the consequences from this important system, as well as from the compound measures, and their use. But the subtilty of a conventional taste, the ignorance and the prejudices so fatal to the progress of the arts, and which are peculiar to narrow minds, will be long opposed to such deduction." We should rejoice if Reicha's anticipated deductions could be verified in our day; but, with all respect for that excellent musician, we rather think that he has too often suffered his reason to be led astray by the incomprehensible idealism and metaphysics, so general in Germany upon almost all subjects of art, science, and literature.

Some peculiarities that have been observed in certain national tunes, such as the omission, in some instances, of the fourth and seventh of the key, have been referred to scales of a particular kind, while it seems more reasonable to refer them merely to the imperfections of some of the musical instruments employed; for instance, the ancient flageolet, and the chalumeau, &c. Scales, seemingly anomalous, may arise from such causes, or from caprice, or conventional usage; but all such scales are only fragments of that general system of sounds which comprehends all manner of appreciable intervals, many of which last are much smaller than is commonly believed. It has been denied that the ancient Scottish music contained any semitones; but that this is an error, is proved by the Skene manuscript in the Advocates' Library, Edinburgh. In the ten Indian scales given by Sir William Jones, we find two that want the fourth and seventh of the key note, and one that wants the third and seventh. The former are the scales called *Māravi* and *Gaudi*, equivalent to *c, d, e, g, a*, and *g, a, b, d, e*; the latter is the one called *Satindhavi*, equivalent to *a, b, d, e, f*. The *Asāvēri*, *Bahairava*, and *Malava*, correspond exactly with the Dorian, the Lydian, and the Myxo-

Lydian modes above mentioned. The *Friraga* is the same as the *Malava*, the *Todi* is the same as our scale of C major, and the *Varati* and *Bengali* correspond with our scale of A minor with minor seventh. As to the Hindu, Persian, and Chinese scales, and the use of quarter tones, or other minute intervals, we refer the reader to what we published on that subject in No. iv. of the New Edinburgh Review, April 1822, pp. 521-528. We have examined a number of Chinese wind and stringed instruments brought home in June 1837, and have found semitones in all of them. Professional musicians who followed Napoleon into Egypt, remarked the frequent and dexterous use of very small intervals by some singers in that country. Dr Burney, in the second volume of his history, p. 424, mentions that the Arabian scale of music is divided into quarter tones, and that each of the twenty-four of these, into which the octave is divided, has a particular denomination.

Music.

At the head of these must be placed the human voice. **Musical in-**
The nearer any artificial instrument approaches to it in qua-
lity and power of expression, the more excellent it is. struments.
Much controversy has arisen regarding the mechanism of the vocal organs which effect the modulations or inflexions of the human voice in singing. Some physiologists have considered this mechanism as similar to that of a reed instrument; others as similar to that of a stringed instrument. It is indeed neither, according to our artificial instruments, but a mechanism of wonderful delicacy and complexity, infinitely surpassing all artificial instruments in variety of *timbre*, in delicacy of intonation, and in power of melodic expression. Some of the most curious inquiries into this subject were made by the late Dr Francesco Bennati, an Italian physician and surgeon, and an accomplished amateur singer, who died a very few years ago in the prime of his life. He says that *phonation* has hitherto been confounded with *modulation*; the sounds of the voice in speaking, &c. with those of the voice in singing. We would observe, that the ancient Greeks, in their writings on music, made a marked distinction in this. Dr Bennati says that the muscles of the larynx are by no means, as hitherto asserted, the only ones employed in the production of the sounds of the human voice in singing; and that from leaving out of view a number of elements which belong to the real mechanism in such production, the theories of the whole matter that have been proposed and received are erroneous. Among these omissions of real elements, he instances the muscles of the *os hyoides*, of the *tongue*, of the *upper anterior* and *posterior part of the vocal tube*, besides other anatomical parts that contribute to modify the voice. We cannot here enter into the curious details given by Dr Bennati; but may add, that he rejects the received terms of *note di testa* and *note di petto*, as conveying false ideas; and proposes to substitute for them the terms *supra-laryngean* and *laryngean* notes or sounds. His proofs of all that he asserts are drawn from his own frequent observation of the actual functions of the whole mechanism of the voice in the cases of a number of the most celebrated male and female singers, his contemporaries. Stretched strings of gut or silk, either plain or spirally covered with wire, are the sonorous bodies employed to produce musical sounds on instruments of the violin kind, or of the guitar kind, or on the harp. Stretched wires of brass or steel, &c. plain, or spirally covered with wire, produce the sounds of the pianoforte, &c. Other instruments are constructed of glass bells or rods, &c. made to sound by friction or percussion; others, again, of metal springs, made to sound by a revolving toothed barrel, as in the Geneva musical boxes; or by a current of air directed against them, as in the German toy called the mouth harmonica, or in the *Æolophon*, or the Accordion and Symphonion. Several other instruments of a similar kind were invented before these. It

Music. may be mentioned, that Professor Robison of Edinburgh University gave the hint for constructing instruments of this last kind.

In the year 1785, the Abbate Gattoni constructed at Como a most singular Æolian harp. He stretched fifteen iron wires, of different thicknesses, from the top of a tower fifty-two *braccia* in height (about ninety feet), to his dwelling-house, about 150 paces distant. This giant-harp, by its mysterious sounds while the air was calm, indicated changes of the weather. This was ascribed to electric influence. The same phenomena occurred in a similar harp constructed by Captain Haas of Basle. The effect of the vibrations of the wires in each of these giant-harps, prior to changes of weather, or during storms, is said to have been quite indescribable. The sounds swelling and dying, and combining in the wildest harmonies, were sometimes heard for miles around. Wind instruments are tubes of wood or metal, in which the vibrating body is the column of air contained in them. They are sounded either by a peculiar mouth-piece, like that of the old flute or the flageolet; or by blowing into an aperture on one side of the tube, as in the fife, german flute, &c.; or by means of a reed, as in the oboe, clarinet, bassoon, &c.; or, as in the case of the horn, the trumpet, &c. by means of a cup-shaped mouth-piece, to which the lips are applied in a particular manner, and the sounds produced by compressions and dilatations of the lips, and the regulated force of the breath, and, in some circumstances, by introducing the hand within the bell-shaped end of the instrument. Other instruments are merely pulsatile, such as triangles, cymbals, bells, gongs, drums, &c., and have their sounds fixed. The harsh and unmusical tone of the gong seems to be owing to its peculiar shape, as well as to the numerous abrupt inequalities in its thickness and density.

With reference to Choron's table of compass of voices and instruments, we have to remark in general, that the best sounds of voices and instruments are their medium sounds, and that this ought to be carefully attended to by the composer. The frequent neglect of this in modern compositions produces a detestable chaos of screaming, squeaking, and grumbling. We add the following supplementary and explanatory information, which is of importance to the student. The medium compass of voices is as follows:

These restrictions are, of course, not intended to apply to solo singers, who have voices of great compass, but to Parts¹ written in songs, duetts, trios, &c. for voices of ordinary compass. It should be kept in view, that in writing for voices of the *same* compass and quality, we can hardly go beyond a trio or a quartett without producing a poor effect. Duetts, or at most trios, of this kind, are therefore best when circumstances require such combinations. But, for *variety* of effects, and freedom of harmonic combinations, three, four, or more voices of different compass, and quality ought almost always to be preferred in vocal trios, quartetts, &c. For *duetts* of this contrasted kind, see the operas of Cimarosa, Mozart, Cherubini, Himmel, &c. To write effective Parts in harmony for voices, requires great skill and judgment. In a vocal quartett, for example, if we throw any of the voices out of their best medium com-

pass, and do not carry them all on in correspondence with that compass, we shall produce poor and ineffective harmonies; for instance, if we place the tenor Part too low and too near the bass, while the treble and contr' alto remain in their best medium compass. Again, we may render the principal Part in a soprano a secondary Part (to the ear), by bringing it and the contr' alto too close to the tenor and bass; and may thus render the tenor, or even the bass, the most prominent Part, when we intended the contrary. In vocal Parts for many voices, such as choruses, &c. great simplicity of structure and of *performance* is required to produce any good effect. In 1819 we witnessed the famous Crescentini's training of a chorus at Bologna. His ear caught in an instant the slightest defect of intonation in any of the voices; the slightest excess of disproportionate *piano* or *forte*; the slightest attempt at any embellishment, even an *appoggiatura*. He stopped the whole performers immediately, pointed out the fault, and made them repeat the music over and over again till he was satisfied. This was the true way to train a perfect choral band; it would be well if his example were followed in all such cases.

Its powers and compass as a solo instrument are very Violin. great, although too often misused. In orchestra music it is seldom carried above F in alt.

In writing for an orchestra, the viola is rarely used Viola. above G, two octaves and a fifth above its lowest sound C. Not unfrequently, in modern music, it crosses the second violin, and rises above it for a short time in the harmony of a quartett, even where it is not performing a solo Part. But this generally occurs for the sake of preserving a melodious progression of the Parts, or of producing some particular effect from the *interweaving* of the different *timbres* of the stringed instruments.

We must keep in view, that the German double basses Double have generally four strings, and that some are tuned E, A, D, G, upwards, while others have D for their lowest note. In Italy and France the double basses have only three strings, and are tuned A, D, G. In writing for the double bass, rapid passages ought to be avoided, because they produce no effect, but only a confused noise. In music for a full orchestra, the double basses are reinforced by the tenor violins and violoncellos, or by the bassoons; or by the trombones, serpent, &c.; sometimes by the horns and trumpets, by the lower notes of the clarinet or of the oboe, even by the flute in its upper octaves, or by the octave flute, though the latter combinations are often abused by some living composers. Sometimes, in a florid passage for the double bass, a good effect is produced by reinforcing it by the second violins. In orchestra music, Violon- the violoncello generally goes (an octave above) with the cello. double bass Part: but beautiful effects are often produced by giving the violoncello a principal melody, accompanied by other instruments. When the treble clef is used in passages for the violoncello, care must be taken to write them according to the real pitch of the sounds, and not an octave higher, as is too often done.

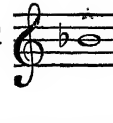

In writing for the German flute, all rapid passages in Flutes. keys having more than one or two sharps or flats should be avoided, as they are very difficult of execution. We have corrected Choron's table, by extending the compass of the flute to C downwards, as most flutes now have the C finger-key. Its compass upwards is to B flat on the fifth ledger line in alt. In modern orchestra music, the octave flute, or *piccolo*, is too much employed. Its shrill and piercing sounds ought to be reserved for particular effects. In military music there are other kinds of flutes used,

¹ In this article, we use the word Part, beginning with a capital, to signify that portion of a musical composition assigned to a particular voice or instrument.

Music. the *piccolo* in E flat, and the *piccolo* in F; the former being a semitone higher, and the latter a minor third higher, than the octave flute. There are also what are called third and fourth flutes, the former being a minor third, and the latter a fourth, higher than the common German flute in D. Parts for these flutes are written in D. There are five sorts of flageolets, in C, D, E flat, F, and G, for the sake of facilitating their performance in different keys. Double and even triple flageolets have been contrived in London by Mr Bainbridge. On the former, two parts can be played at once; on the latter, three. The oboe requires attention in writing for it. The easiest scales for it are C major, F major, G major, and D major. In some modern oboes, there are, in the upper part of the instrument, finger-keys for F and A flat; and, in the middle part, for F sharp, E flat, and C. Some have a finger-key for the lowest C sharp. Some players have two or three upper and middle pieces, to serve for altering the pitch of the instrument to different keys, on the same principle as flutes and clarinets, &c. are made of different lengths to avoid difficulties of fingering. In orchestra music the oboe is not used beyond E flat in alt.

English horn. The English horn, or *vox humana*, is an instrument of the oboe kind, having the same relation to the oboe that the viola has to the violin. It has the same number of sounds as the oboe, only the scale is a fifth lower; so that pieces of music in F are written in C for the English horn, pieces in E flat are written for it in B flat, and so on.

Clarinet. The clarinet, or clarionet as it is often called, is an instrument of great power and compass. We have corrected Choron's table, by extending its compass upwards to C above fifth ledger line in alt. The sweetest sounds of the

clarinet are comprised between  and  **Music.**

The sounds between B on third line of treble clef and C# on second ledger line above are the most penetrating and brilliant. The sounds above that C# are very difficult to produce without harshness of tone. It requires great skill to play in tune on this instrument, particularly in the lower part of its compass. On this account, as well as to avoid difficult fingering, clarinets of different sizes are used to suit different keys. The most common used in orchestras are those in C, in Bb, and in A. Besides these, there are used, in military bands, clarinets in D, Eb, F, and G. These changes alter the pitch of the instrument, but the fingering remains as before. Thus the pitch of a Bb clarinet becomes in its lowest sound ; that is, a

tone lower than the C clarinet. The pitch of the A clarinet in its lowest sound becomes , and so on.

It is the custom to consider the principal key of every clarinet, whatever that may be, as if it were C. The composer must attend to this in writing for the clarinet. The Bb clarinet serves to lessen the number of flats at the clef, and the A clarinet to lessen the number of sharps, and so of the others. When the piece of music is in Eb, the Bb clarinet plays in F. The A clarinet plays in C when the piece is in A. If the piece is in Ab the B flat clarinet plays in Bb, and so on. An example or two will make this rather puzzling matter more clear.

Clarinet in Bb. Clarinet in A.

Violin. &c. Violin. &c.

Clarinet in Bb.

Violin. &c.

A few years ago, a German instrument-maker invented a bass clarinet and a double-bass clarinet. The former is an octave lower than the C clarinet, and reaches Bb, the lowest note of the bassoon. The double bass clarinet has a compass of two octaves and a half upwards from the lowest F in bass clef. It therefore extends to a fourth below the bassoon. The union of these with common clarinets permits the formation of a clarinet quartett, and, of course, new orchestral effects.

Basset-horn. The basset-horn is an instrument of the clarinet kind, although differing in form from a clarinet. Choron has omitted it in his table. As it is sounded and fingered like a clarinet, any clarinet-player can play upon it also. It holds a middle place between the clarinet and the bassoon.

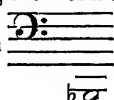

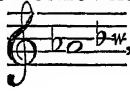

Some authors give it a compass of four octaves from

 to ; others a compass from  to 

 As it is an instrument difficult to manage, it is generally confined to the keys of C, F, Bb, and G. **Music.**

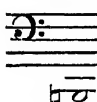

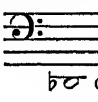

Music. sic for the basset-horn is written in the treble clef, and a fourth or a fifth higher than the real sounds, except in the case of arpeggios, &c. in its lower octave, which are expressed in the bass clef. For instance, if the music is in G or in F, the part for the basset-horn will be written in C. For examples of its use, see Mozart's *Requiem*, his *Figaro*, his *Clemenza di Tito*, and his *Die Entführung aus dem Serail*. It is too much neglected in orchestra music.

Bassoon. The bassoon is an instrument of the oboe kind, though it differs from the oboe in shape and construction. It holds the same place among the oboe class of instruments as the violoncello does among the violin class. Some writers state its

compass to be from  to , or even to

 among solo-players. Music for the bassoon is

written in the bass clef for the lower sounds, and in the tenor clef for the higher ones. The easiest keys for it are C, F, Bb, and G. In general it wants the sound

, and the sounds  are very bad,

and must be avoided.

Of late years, some bassoon-players and instrument-makers have facilitated the execution of certain passages on that instrument by a new disposition of the finger-holes and the finger-keys. In orchestra music, bassoons are important instruments. They serve as a bass to the flutes, oboes, clarinets, and horns; they may fill up and enrich the harmony of the middle parts; they may go along with (in the octave or the unison, as may suit) and reinforce the double bass, the violoncello, the viola, the violin, the clarinet, the oboe, the flute, the horn; or they may perform solo passages of their own with great effect. Composers seldom put the bassoons to their proper and effective use, but too often make them a mere reinforcement to the other bass instruments.

Bass-bassoon. The bass-bassoon (fagottone or contra fagotto) is an octave lower than the common bassoon. It is not mentioned by Choron in his table. The first bass-bassoon seen in England was made by Handel's orders, for the use of Lampe, an excellent bassoon-player, and author of the music of the *Dragon of Wantley*. Being an unwieldy instrument, sixteen feet long, it was necessary to fix it in a frame like a telescope.

Serpent. The serpent is chiefly used in military music, but has of late been introduced into orchestra music to reinforce the basses. Mersenne says that a serpent played by a boy was sufficient to sustain the voices of twenty stout monks. Of late years some improvements have been made on it by the addition of keys, though it is still an imperfect instrument. Writers differ in the compass assigned to it. Some give it a compass from the lowest B flat of the piano-forte, up to G on the second line of the treble clef, with all the semitones. Others state its compass to be from lowest C of violoncello, up to C in third space of the treble clef. One eminent writer says that its compass is four complete octaves; that is, from C an octave below the lowest C of violoncello, up to C in the third space of the treble clef. He says the lower notes, in this last compass, are very difficult to produce, and their intervals not easily appreciable. Reicha assigns to it a compass of three octaves, viz. from lowest C of violoncello, up to C in third space of treble clef. The safest compass for ordinary players is the two first of these octaves only, leaving out the highest of the three. It is a singular fact, that there exists at this

day, even among many professional musicians, a great deal of misconception regarding the real compass of a number of musical instruments of the wind kind. We have often been surprised to find that a performer upon a horn, for instance, did not know its real pitch or compass, and that he even supposed these to be just what appeared from the notation in the treble clef. Now, a C horn, for example, is a tube of eight feet or so in length; and, when played upon, becomes a tube stopped at *one end* by the lips, and therefore may render, as its lowest possible sound, one equivalent to that produced by an organ-pipe of sixteen feet open at both ends; that is to say, = C an octave below the lowest C of the violoncello. The serpent, if a tube of the same length, will, when played on with all the finger-holes stopped, be in a condition to render (but, like the horn, with great difficulty) the same low C as the horn.

The name of this powerful brass instrument (from the Ophicleide. Greek *ὄφις* and *κλείς*) signifies a keyed serpent. The ophicleide was invented a few years ago in Germany. It was at first used in military music only, but of late years has been introduced into orchestras. It is too noisy an instrument for any place but a large locality. There are several kinds of ophicleides, as of trombones, and music for the former is written in the same manner as for the latter. Examples of the judicious use of the ophicleide may be seen in the *Gloria* and subsequent movements, and *Marche Religieuse* of Cherubini's third solemn mass performed at the consecration of Charles X.

Whatever may be the key of the piece of music in Horn (Ital. *Corno*) which horns are employed, their Parts are always written in the key of C. The following is the harmonic progression of sounds producible by the horn, without any assistance from the hand introduced into the bell.

The sounds marked + are, successively, = to B flat, harmonic; G flat, ditto; and G sharp, ditto. See preceding section, *Musical Sounds and Intervals*. We may here remark, once for all, that the sounds called false and bad on the horn, trumpet, &c. such as the pseudo fourth and sixth and flat seventh of the scale, are *true* as *chromatic* harmonics, but do not correspond with the sounds found in the same nominal places in the *diatonic* scale. In treating of harmony, it will be seen that these same chromatic harmonics—called false sounds from their not belonging to the diatonic series—are frequently employed in modern harmony and melody. The dominant seventh continually occurs, and less frequently the diminished fifth and the augmented fifth, which are the other two harmonics in question. It must be observed, that if a horn in C, of eight feet tube, performs the above notes, the real sound of each is an octave lower than the notation indicates. Of late years it has been attempted to remedy the imperfections of the horn, and to render it capable of playing in a variety of different keys without difficulty. This was so far done in Italy in 1822, by means of eight finger-keys, and a sliding tube to regulate the pitch; but this improvement has not been generally adopted. Some German instrument-makers have also contrived stops, to be pressed down by the fingers, which are said to answer much better than keys. They have also applied these stops to trumpets and trombones. This has also been done in England. We shall consider only the common horns, as they are still used in some orchestras. The method generally adopted to alter the pitch of a horn, is to shorten or lengthen its tube by means of moveable bent tubes called *crooks*. In some few cases, horns of different sizes are used instead. Thus there are horns in C, in D, in E flat,

Music. in E, in F, in G, in A flat, in A, in B flat, and even in C above. There are two B flat horns, the one an octave lower than the other. The lowest B flat horn goes a tone lower than the lowest C of the C horn. In writing for the horn, it is necessary to mark, at the beginning of its Part, for what key it is intended, as in the following examples. The Italian word *corni* (horns) is generally used in partitions. **Music.**

Corn in D. Corni in Eb. Corni in A.

Real Sounds. Ditto. Ditto.

In general, in writing for an orchestra, there are two horn Parts, the first of which does not (by notation) go lower than the lowest C in the treble notation, and the second one not higher than E in the fourth space of treble clef. The compass is generally limited to the following

sounds, But in solo Parts

for the horn, the compass is as follows, a number of the semitones being produced by a dexterous use of the hand within the bell of the instrument.

The notes marked + may be used in passages of some quickness, but should never be sustained. The sounds of the middle part of this compass, or at least from G on second line of treble clef to G above the fifth line, are the best. In modern orchestra music, the proper use of the horns is too often lost sight of. They are either too much employed, or used in passages quite unsuitable to their character and powers. Their best effect lies in sustained sounds, not in rapid passages. They should be used to enrich the harmony in proper places, or to sustain a principal melody, or to produce contrast by their solos judiciously introduced. By using at once three or four horns tuned to different keys, a number of rich and beautiful harmonic effects have been produced by modern composers. As the sounds of the middle compass of the horn are the best, judicious composers for that reason often make use of horns in a key different from that of the piece of music in which these take part. Sometimes, but rarely, we find horn Parts written in the bass clef, as more truly representing the compass of the instrument; but it is better to avoid difficulty in reading such notation, by conforming to the usual practice of writing horn Parts in the treble clef. Skilful horn players expend but little breath on their instrument, and thus produce its finest tone. Others not only exhaust themselves by strong blowing, but produce a harsh tone, and fill the tube with water from their condensed breath. This water contributes to spoil the quality of the tone, and to break it into gurgling sounds.

commonly used; but there are also trumpets in A, Bb, E, F, and G. It must be observed, that in some of these, F and G, for example, the gravest sounds are very difficult to produce. Some very skilful performers execute all sorts of passages on the trumpet; but, in writing for an orchestra, we ought not to go beyond rapid passages of double or triple tonguing upon a reiterated sound, or certain arpeggio passages. The trumpet may be either played softly, like the horn, or loudly with tongued passages, as in military music. To perfect the trumpet, finger-keys have been applied to it by some makers, and a sliding tube by others. Whatever the key of the music, the trumpet Part is written in C. The pitch of the trumpet is an octave higher than that of the horn. Its natural scale is

The notes marked +, like those of the horn, do not correspond with the diatonic series, and should not be used in sostenuto passages. The best notes are from

up to and those higher had better be avoided.

Trumpet.

Trumpets in the keys of C, D, and Eb are those most

Trumpets in D.

Trumpets in E.

Effect. &c. 3 &c.

Music. Trumpets, as well as horns, may be muted by introducing a pasteboard tube into the bell of the instrument. The sound then becomes extremely feeble, and the pitch is lowered a semitone. By using two trumpets in different keys (as in the case of horns), a number of harmonic combinations in minor keys may be introduced which could not otherwise be effected; also by combining together two or more horns in one key, with two or more trumpets in another. The penetrating and warlike sound of the trumpet renders it very effective in pieces of military music, and in music expressive of heroic or exulting feelings.

Trombone.

The trombone is a most powerful and effective instrument, but very difficult to manage correctly. In Italy the bass-trombone only is used; but in France, Germany, and

England, there are three kinds of trombones, the bass, the tenor, and the counter-tenor. There is also a *double-bass trombone*, which goes a fifth lower than the common bass-trombone, but is not much used. The treble trombone is very rarely used; and it is better to add to the three former another counter-tenor trombone when four trombones are to be employed, than to add a treble one. In the performance of solemn, religious, or warlike music, the combination of three or four trombones produces a great effect; for instance, in the statue scene in Mozart's *Don Giovanni*, where the supernatural voice is accompanied by three trombones, two bassoons, two clarinets, and two oboes. The effect of the chant so accompanied is terrific. Mozart borrowed the idea from that passage in Gluck's *Alceste*, where the voice of the oracle of Apollo is heard in the temple.

Music.

Scales of Bass, Tenor, and Countertenor Trombones.

Parts for trombones are written in the above clefs; and, as in the case of bassoon Parts, the key is marked at the beginning, or accidental sharps or flats introduced when required. It is to be noticed, that there are trombones in different keys, for different purposes: in F, C, G. Sustained sounds are most suitable to the trombone, especially in orchestral combinations. A very few players are so skilful as to be able to execute very difficult solos on the trombone; such as Schmidt, who performed on it in London in 1829. The trombone can be *muted*, like the horn or the trumpet, and then its effect in funereal music becomes very striking. Chromatic passages ought, in general, to be avoided on this instrument.

Kettle-drums.

Kettle-drums, called *Timpani* in Italian, are tuned to various keys, as occasion requires. They are generally in pairs; one of them sounding the key-note of the music,

and the other the 4th below, as &c.

The Part for them is always written in the key of C, whether the key of the music be C or not; but if it be another key, this is marked at the beginning, as

Drums in D. Drums in E \flat .

&c. It has been proposed to introduce into orchestras three drums tuned to different sounds; and perhaps there might often be advantage in this. We have seen a vocal and orchestral composition for forty voices and forty-two instruments, in which eight kettle-drums were employed. They were to be played by four persons, and were tuned thus: from G upwards, A flat; A, B flat; C, D flat; D, E flat.

The *roll* of these drums, when executed *piano*, has a sombre and mysterious effect. It is usually marked *tr* or *tr* over the notes. Clarinets, horns, trumpets, and drums, may be changed for others in the course of a piece of music, provided a sufficient number of bars of rest are given.

Bass-drum.

Tamburone in Italian, or vulgarly *cassa grande*. This is a very large drum, of the usual cylindrical shape, and is

used chiefly in military bands, but occasionally in great orchestras. In Haydn's symphony, called the *Surprise*, it is used with startling effect. Its Part is written in the

bass-clef thus:

The gong is occasionally used in theatrical music, to *Gong* add to the effect of scenes where terror and confusion predominate.

The Chinese pavilion, the triangle, the common drum, Chinese and cymbals, are almost entirely confined to military music, though they are sometimes used in theatrical orchestras. In Mozart's *Die Entführung aus dem Serail*, the orchestra Parts of the duett "*Vivat Bacchus*" contain bass-drum (*tamburo grande*), triangle, and cymbals (*piatti*). Parts for the triangle, Chinese pavilion, and cymbals, are written in the treble-clef upon C the third space.

To point out all the difficulties of the wind-instruments above mentioned, and all the particular passages that should be avoided in writing for them, would occupy a volume. We shall merely notice, that in the flute, oboe, clarinet, and bassoon, the finger-keys of these instruments often render the performance of certain *legato* passages impracticable, and that therefore the composer ought to make himself acquainted with all these niceties. If he do not, his music, however excellent in other respects, can never produce the effects that he intended. We have dwelt more at length upon these matters regarding voices and instruments, because they are really of great importance to the musician and the composer, and because they have been hitherto too much neglected in our British treatises upon music. What we have stated in our general view of voices and instruments will preclude the necessity of entering into details regarding most instruments under their alphabetic heads in other articles of this Encyclopædia.

The guitar, the harmonica, the harp, the organ, and the piano-forte, are mentioned in Choron's table; but we have no particular remarks to make upon them in this place. We shall have something to say of the organ and the piano-forte in speaking of accompaniment, in the course of the present article.

Table of the Compasses of Voices and Instruments.

Music.
Melody.

Melody may be considered in relation to a single voice or instrument, or as accompanied by one or more voices or instruments. In the latter case it is called the principal melody. There are many simple and expressive melodies, of such a kind that they will hardly bear any accompaniment without injury to their effect. Too often such melodies are spoiled by the addition of crowded and elaborate accompaniments, having nothing in common with the melody in style or character. This is one of the great mistakes of the modern schools of music, though we have no doubt that a better taste will prevail when more study is bestowed upon melody as the most important part of musical composition. We cannot too often repeat, that harmony ought always to be considered as subordinate to melody, although we are aware that certain great and peculiar effects may be produced by harmony, independent of melody in the true sense of the latter term; for instance, such effects are heard in certain forms of solemn ecclesiastical harmony that contain hardly a vestige of melody. The effects of mere harmony are often very striking when produced by a certain combination of voices, or of instruments, or of both, and in a building sufficiently spacious and suitably constructed, or even in the open air when heard at a certain distance, and especially if they pass over an expanse of still water. In ancient ecclesiastical music, the length of the sounds and the simplicity of the harmony were well calculated to produce a great effect in large cathedral churches. In such places, rapid changes of sounds, and chromatic harmonies, never produce any thing but confusion; and this ought to be kept in view by the young composer. He must calculate the effect that his music will produce in a cathedral or in a theatre, a concert-room or a private room. No one who has not observed the difference of effect produced by the same music in places of different size and construction, can understand how important it is to attend to all this. But we must not encroach here upon another section of this article.

The study of melody is by far too much neglected. Harmony has generally in these days usurped its place; and we find ten good harmonists according to rule, for one good melodist. The reason is, that a man without real musical genius may become a very good scholastic harmonist, while a great melodist must be a man of great genius. Handel was in his day one of the most remarkable musicians for general excellence in both melody and harmony; but he was a man of the highest musical genius, and his profound skill in all the harmony of his time could never altogether check the flow from the spring of melody which existed in his mind. In his oratorios and his operas that spring is never failing. It is a pity that Handel's operas are now so little known. They contain much beautiful melody, although that is often disfigured (as in his oratorios) by conventional passages of a formal kind, which must, like all other such passages, become quite antiquated after a short time, having no foundation in any thing but temporary fashion of style.

In the proper order of musical study, melody ought to precede harmony. It is from reversing this order that so many dry unimaginative harmonists have been produced;—men actually rendered incapable of composing good melodies, or of appreciating their beauties when heard. The student ought to have daily before him specimens of the most beautiful and expressive melodies in all styles, and of all nations. It is much to be regretted that there has not been published any judicious and comprehensive col-

lection of such melodies. It would be invaluable to the student.

One of the earliest writers who treated of melody was Salinas, a Spaniard, and blind, but an eminent musician, and professor of music in the university of Salamanca. His work, which is now very rare, was published in Latin in 1577, at Salamanca. The fifth, sixth, and seventh sections of it are devoted to the consideration of the nature of musical, oratorical, and poetical rhythm. There is a great deal of curious and instructive matter in these sections, and he illustrates his text by numerous fragments of melody, some of which are very interesting, being old Moorish, Spanish, or Italian melodies. We have given some of these as curiosities in Plate III. Salinas says (page 235), "In the three following books (sections) we have to treat of the rhythmic part of music, a part of it not less useful, and even more delightful, than the harmonical part."

Another of the earliest writers on melody was G. B. Doni, the Florentine musical amateur and antiquary. Among his published works (3 vols. folio, 1763) we find many sensible remarks upon melody, and some curious notices of the distinguishing characteristics of national melodies (see, in particular, his *Trattato della Musica Scenica*, vol. ii. of his works). Speaking of the remarkable difference in the pronunciation of Latin by the French, Spaniards, and English, as compared with its pronunciation by the Italians and Greeks, he says, "This difference arises from the diversity of the accents, and the elevations and depressions of sound."... "We may say that common speech is a kind of outlined melody; and the mode of speaking in the recitation of poems, a kind of shaded melody, half finished; while true melody, called by the Greeks *ᾠδὴ μελὸς*, is perfect and finished, and, as it were, completely coloured." (P. 18 of *Trattato*.) With regard to setting of words to music, he says, "One of the most important remarks, and one perhaps not attended to by any person at present, is, that the music should not imitate the words, but the whole sentiment of the poetry; for in this consists true musical expression." He adds, that "Mimics and buffoons adopt the other mode; and, by exaggerated looks, and gestures, and noises, attempt to enforce the words they utter, or to represent the passions they are supposed to feel. (P. 29.) "Melopoeia is the art of composing beautiful melodies, without any reference to counterpoint, which belongs to another part of music." (P. 35.) As to modulation, he says, "The moderns are too scrupulous in wishing to keep always in the same key; a custom perhaps derived from the ecclesiastical chants, but quite unsuitable to varied and scenic melody." (P. 33.) Chapter xvii. of Doni's *Trattato* contains a number of ideas which Reicha has borrowed and developed in his *Treatise on Melody*. Doni proposes the use of *quinary*, and even

septenary measures, such as $\frac{5}{2}$, $\frac{5}{4}$, &c., or $\frac{7}{2}$, $\frac{7}{4}$, &c. Reicha

has also proposed the adoption of the quinary measure, and gives a specimen of its use in a national dance-tune of the district of Kochersberg, on the Lower Rhine, in the old province of Alsace. Reicha says, from information sent to him, "The manners and customs of the inhabitants of Kochersberg distinguish them completely from the other people of Alsace. Their dances have a particular and remarkable character, and nothing in common with those of their neighbours. The tunes of these dances have a very decided measure of five times. Tradition, in the country, carries back this music to the remotest antiquity."

Music.

Music.

William Shield, a clever English composer, introduced a movement in this quinary measure into one of his instrumental trios. Two or three other Englishmen, and several Germans, have attempted the same measure; but it has not been generally adopted, though there is no reason but *custom and habit* why it should be rejected. Doni says (p. 74 of *Trattato*), "If the septenary measure could be conveniently adopted, it would produce a more remarkable effect upon the ear than any other, and it would suit lachrymose and compassionate subjects. But we let this alone, because it will be no small matter if we bring the quinary measure into use."

The following passage from Doni relative to national melodies is interesting, as having been written more than two centuries ago: "Although Italian music seems the most excellent and varied of all, still let us remember that *non omnis fert omnia tellus*; but that one nation abounds in one thing, another in another thing, according to the different genius of each. Therefore the judicious composer may draw from French airs (which have great variety and lightness in lively subjects), good passages and spirited and pleasing melodies. From the old Spanish airs he may derive many hints regarding melody and rhythm, for grave and majestic subjects; for example, from the Pavana; and from modern airs, and those borrowed from the Moors, he may also draw beautiful and lively melodies, but more soft and effeminate. Portuguese melodies may afford him very tender and affecting passages; and, for mournful and lugubrious subjects, he may enrich his imagination with Sicilian melodies, although they have little variety; and if he will go farther, he will find in English" (Scottish? Irish? Welsh?) "and German airs something to imitate in certain bold and military conceptions; there being perceptible in these airs, especially the German, a certain manly and military character," &c. (P. 131, *Trattato*.) The Spanish ex-jesuit Eximeno, in his work *Dell' Origine, &c. della Musica*, published in 1774, says, "In Italy national airs are not common, for most of the people have so fine an ear that it is enough for them to hear the opera airs, in order to amuse themselves afterwards by singing them in the streets." However, he adds, "The country people and villagers have their songs and tunes in a simple style, but in good taste. The romagnella, which they sing accompanied by the colascione, is full of good taste, and still more so the tamburo of the Trasteverini. The taste for songs reigns chiefly in Venice; and although they are usually composed by professional musicians, the people learn them easily."

In Plate III. we give the tamburo, No. 1, and a beautiful Venetian air from Eximeno, No. 2. The tunes to the Spanish romances Eximeno thinks "monotonous and tiresome," and believes them to be remnants of Moorish melody, or else ancient sprouts of the Canto Fermo. "The most tasteful popular songs of Spain are the Seguidillas, of which there is an endless variety." (See Plate III., No. 4.) We have given a few other specimens of curious melody which have not before been published in Britain. Among these are (Plate IV.), No. 15, a German melody of the year 1425; No. 17, Egyptian air, performed "with all their might" by the musicians of Grand Cairo, when the principal inhabitants, headed by all the sheiks of the town, went to meet Bonaparte on his return from the Syrian expedition. It was dictated by the chief of these musicians to one of Napoleon's. The performer accompanied it on the instrument called in Arabic *al aoud*. Hence the English name of *lute*, Spanish *laudo*, Italian *luto*, French *luth*. No. 18 is a song and chorus of cannibals. This curiosity was written down by a Russian voyager (Councillor Tilesius) in 1804, and published in the *Leipsic Musical Gazette*, No. 17, in 1805. Tilesius passed a night in listening to this music among these savages, in

one of the islands of St Christina. He says, "there was something frightful in this melody, which almost drove one to desperation, and seemed to make one hear his own funeral dirge." He mentions, as a curious circumstance, that the voices of these savages passed, by sliding through very small intervals, from the E to the G of this chorus, or the converse. The savages, several hundreds, men and youths, sung it in unisons, or octaves, and danced at the same time. They marked the measure by clapping their hands, and also by beating drums. Tilesius explains the meaning of this chorus. "The warriors have returned from battle. It is night. One of them perceives a distant fire on the enemy's island. He asks, 'Where is the fire?' The chorus answers, 'Upon Tanhuatah Montanloh, among our enemies! they are roasting our dead and the captives!' This renders them frantic; they call for fire immediately, and feel a pleasure in being able to use it in reprisal against the dead, and prisoners taken from the enemy, but not without compassion in thinking of the wives, the children, the relatives, who will weep at that moment. Finally, they reckon the days from the first to the tenth, indicating the time fixed for feasting upon the victims, and for solemnizing the victory." An English writer of the last century, when speaking of Scottish music in one of his essays on various subjects, says, "Who was it that threw out those dreadful wild expressions of distraction and melancholy in *Lady Culross's Dream*? an old composition, now, I am afraid, lost; perhaps because it was almost *too terrible for the ear*. I'll venture to swear that David Rizzio was as innocent as any lamb of all such frantic horrors." The examination of the melodies Nos. 1 to 18 inclusive will suggest matter for reflection. We would point out especially the elegance of No. 2, the expressive character of No. 4, the beauty and absolutely *modern modulations* of No. 14 (of fifteenth century), the curious rhythm and changes of measure in No. 15, the wild and singular cast of the Egyptian air, No. 17, and the hideously lugubrious character of the cannibal chorus, No. 18. Burckhardt, Bowdich, and some others, have published curious specimens of African melodies. We can only refer to these, and to a great variety of national melodies, Russian, Danish, Swedish, Norwegian, Polish, Bohemian, Hungarian, Greek, Spanish, Italian, Sicilian, Welsh, Irish, Scottish, &c. &c. that have appeared from time to time in collections, or detached. Among foreign national airs, we may mention some rescued from obscurity among the mountains of Auvergne, by that admirable English amateur and accomplished composer, the Honourable George Onslow. He has introduced some of these interesting national tunes of Auvergne into his violin quartets, &c.

Reicha, in his *Traité de Melodie*, is the latest writer upon this subject. Several valuable works upon it by Italian and German writers had preceded Reicha's treatise. Among these writers may be mentioned Pisa, Sacchi, Nischellman, Riepel, Koch, &c. A translation of Reicha's Treatise on Melody, with some judicious notes and modifications, would be a useful offering to British students of music. Before we proceed farther, we must advert to what we consider as an error in treatises on melody or harmony. We allude to what are called *passing notes*, or *unreal notes*, and which are said not to form any *real* part of the melody or the harmony. It appears to us very plain that this is a mere fallacy, and that *every sound* that is *actually heard* in a melody or a harmony is just as *real* a sound as any other can be. For example, we take the following melody:

No. 1.

Music.

Music. And then this one, No. 2.

Music.

We shall be told that this No. 2 is only No. 1 varied, or embellished by notes of grace, *passing* notes, *unreal* notes, that do not belong to the melody. But No. 2 is a melody *per se* as much as No. 1; and supposing No. 1 had never existed, No. 2 would still be a real melody, and all its sounds *real* sounds. It would startle us were a poet to say, "Such and such words in my poem are not to be taken as *real* words, but merely as *passing* shadows of words that do not belong to the language, or melody, or harmony, or meaning of my verses." There can be no doubt that if we pre-establish a certain chord, we may say that any sound that does not form one of the sounds of that chord is not a sound belonging to it. This is easily exemplified.

No. 1.

But suppose that the notes F#, D#, B, C#, in the above passage were to occur as *real* notes in a melody—and might they not do so?—what then becomes of their *unreality*? For instance,

No. 2.

Were all the sounds of the following passage (a) performed with perfect equality of intensity and duration, no strong nor weak times would be perceived; and yet it is divisible

into exact measures of different kinds, producing different rhythmical effects, as at (b), (c).

Sometimes, to produce a particular effect, the accent or emphasis is thrown upon the weak times of the measure.

It is plain enough that the simplest elementary forms of musical measure are the binary and the ternary, and that the compound forms arise from a duplication, or quadruplication, &c. of the binary, or a duplication, triplication, &c. of the ternary, or by certain combinations of the binary with the ternary. In the latter case, we have quinary and septenary measures. The last of these is not in use, but the former is occasionally employed. It may be remarked, that although these quinary and septenary measures are generally avoided by composers, yet *periods* of melody containing five or seven *measures* are of frequent occurrence. In binary and quaternary measures we often meet with triplets which really belong to a measure ternary or senary, &c.

Thus (d) produces on the ear the same effect as (e), and (f) the same effect as (g); so that there would really be no impropriety in writing (e) for (d), or (g) for (f). Haydn's beautiful canzonet, *O Tune! Voice*, and the *larghetto* movement of Beethoven's charming *Adelaida*,

are examples of the use of compound ternary measures; while the sign C at the clef, and other circumstances of notation, lead one by the eye to infer that the measures are compound binary ones. But the effect upon the ear, from the predominance of continuous triplets in the ac-

Music. companionment, is that of compound ternary measure. A curious instance of the intermixture of different measures in melody and harmony occurs in the dance-scene near the end of the first act of Mozart's *Don Juan*, where there are three different orchestras, each playing a different tune, one in $\frac{3}{4}$, the other in $\frac{3}{8}$, and the third in $\frac{2}{4}$. Intermixtures of different measures were not uncommon in the works of composers of the fifteenth and sixteenth centuries, but generally produced nothing better than confusion.

The only modern music that is not divided into measures is simple recitative. It has often been desired by composers of music, that the inflexions, the varying sounds of declaimed language, could be reduced to a musical notation more delicate and accurate than the one in common use. To enable us to express such inflexions, a notation for *very minute* intervals, as well as for peculiar accents, would need to be contrived. The attempts to express such declamation are represented by recitatives and *arie parlanti*. Some of these are remarkably expressive, from their near imitation of the inflexions of the voice in declamatory and impassioned language; among others, those of Gluck and Piccini. Beethoven, among the very few remarks that he has left to us upon recitative, says, "Recitative ought to be declaimed as if it were spoken. It is a discourse sometimes accelerated, sometimes retarded, according to what is required by the impassioned expression of the words. The comma, the semicolon, the colon, the

period, the sign of interrogation, and of exclamation, each require a different accent." "To compose a recitative well, it is useful, previously, to declaim the poetry to one's self, as an intelligent actor would do. Any composer who has not ability to do this, ought not to be ashamed to have recourse to some one who can aid him." The best composers of recitatives have carefully studied the declamation of the great actors of their day. The danger lies in imitating false inflexions of the voice, intended to express natural feelings or passions.

We shall now give a brief statement of some of the chief points in Reicha's Treatise on Melody, referring the reader to that work for all developments and minutiae. The treatise consists of a hundred and twenty-three quarto pages of letter-press, and seventy-five plates. "Melody is nothing but a succession of sounds; but if these sounds were placed at random, they would form no sense, that is to say, no melody. It is the same as in regard to words not connected by syntax, nor directed by the understanding. The circumstances that connect sounds together so far as to form a musical sense, are, 1. the key; 2. the measure; 3. the different durations of the sounds; 4. the slurs which connect these more closely; 5. the rhythm; 6. the perfect equality of the *timbre*; 7. the period in which the sense is more developed; all this being guided by feeling and taste. Ideas and periods are separated from each other by points of repose, which are cadences of different kinds. In order to see how all these objects form melodic ideas, and contribute to connect them together, it will not be superfluous to analyze here the following period:

PERIOD.

First Melodic Phrase, composed of three designs.

Second Melodic Phrase, composed of three designs.

(First Member. First Rhythm.) (Second Member. Second Rhythm.)

Allegretto. $\frac{1}{4}$ cadence. $\frac{1}{4}$ cad. $\frac{1}{4}$ cad. $\frac{1}{4}$ cad. $\frac{1}{4}$ cad. Perfect cad.

The following are Reicha's explanations of technical terms, which he uses in his treatise on melody.

"1. A *quarter cadence*, or a point of repose weaker than a half cadence, and which serves to separate one melodic design from another.

"2. A *half cadence*, which separates one member and one rhythm from another, and which ought consequently to be stronger than the preceding cadence.

"3. A *three-quarter cadence*, which is stronger than the half cadence, and weaker than the full cadence, but which terminates a period as well as the latter, the difference, between them existing only in the key in which we end. Thus, the first period of an air of two strains which ends on the dominant, would be only a three-quarter cadence, because another period is required in order to return to the tonic.

"4. *Perfect cadence*, which terminates the period in a positive and indubitable manner; but which does not hinder other periods from being added, if this be thought proper.

"5. *Interrupted cadences*, where, instead of the final sound, we fall upon another, or else leap suddenly from the final sound to another sound.

"6. *Melodic design*, a short musical idea separated from another by a quarter cadence. Two or three of these designs may form a member, which last ought to form a half cadence.

"7. A member of a period is composed of one or of several designs, and ought to make up a rhythm, and form a half cadence.

"8. A *period* may be composed of different designs and of different members. Its cadence is final, or else a three-

quarter cadence, which may be called a perfect cadence relative to the key.

"9. *Rhythm* is the extent or the symmetrical and comparative number of the melodic members. It may have all the cadences except the quarter cadence.....Measure divides into equal parts a series of simple times, as, for example, crotchets in common time; and rhythm divides into equal parts, and consequently in a symmetrical manner, a series of measures. Hence we may say with propriety, that measures are simple times of rhythm, as the crotchets and rests are the simple times of a measure.

"10. *The complement* is a little melodic design that fills up the pauses which occur between the members.

"11. *The supposition* is a measure which, in the theory of rhythm, counts as two; 1. as final measure of the first rhythm; and, 2. as initial measure of the following rhythm.

"12. *The echo* is the repetition of a part of a melodic design, executed by other instruments, and which is not reckoned in the rhythm.

"13. *The coda* is the confirmation of the end of a piece of music. It is also sometimes employed at the end of a period, either at the beginning or in the middle of the melody; but in this case it is short. When it terminates a piece, it ought to increase the animation of the music. It is for this reason that interrupted cadences and the supposition are employed in it, and that it is often executed with an accelerated movement. As to the length of the coda, it depends upon the duration of the piece. When the coda finishes a grand piece, it may be compared to the peroration of an oratorical discourse."

We pass over Reicha's explanations of "Le Retard de

Music. la Cadence," and of "Le Conduit," as these relate merely to arbitrary embellishments introduced just before a final cadence, or between one period and another.

To please a vitiated public taste, most modern performers make an overwhelming use of such *embellishments*, as they are called. Among singers, for instance, none would be listened to who did not prepare to conclude every melody, no matter how simple and unsuited to such trappings, with a flourishing cadenza and a long *shake*. Pietro Verri very properly abominates all such formal shakes and cadences, and desires all rational melodies to be finished off by a simple appoggiatura. G. M. Raymond, writing in 1811 of singers of that time, says: "L'un chante avec les épaules, les bras, les coudes, le corps tout entier; l'autre pousse des cris et pratique des élans qui prouvent suffisamment ses bonnes intentions; celui-ci se livre à des mouvemens convulsifs qui peignent l'excès du sentiment; celui-là à des efforts semblables à ceux qui accompagnent les nausées, et qui ne remplacent pas mal les mouvemens de l'âme et les accens du cœur," &c. All this applies too nearly to many of the singers of 1837.

Among most writers upon music, we find great confusion regarding *feet, cæsures, phrases, clauses, sections, times, rhythms*. We think that, in general, Reicha has been more successful in clearing up and simplifying these matters. His

$\frac{1}{4}$, $\frac{1}{2}$, and $\frac{3}{4}$ cadences come in place of the confusion of cæsures, phrases, clauses, &c. He shows, by numerous examples, the nature of these melodic cadences, and of the final cadence or period; and also of melodic designs, members of periods, periods, rhythms, &c. A discrepancy occurs in what he says (above cited) regarding $\frac{1}{4}$ and $\frac{1}{2}$ ca-

dences in melodic *designs* and *members*; and we have to object to what he says about the *supposition* (article 11, *supra*), as being a measure that counts as two in the theory of rhythm. In a matter of this kind there are really no *suppositions* made by the ear. It hears neither more nor less than what it hears. As to the echo (article 12) "not being reckoned in the rhythm," we conceive that it ought to be just as much so as any other passage in the melody. Reicha refers to Haydn and Mozart as models of skill in the development of a melodic subject, and we cordially agree with him. He says that a treatise upon melodic

modulation is wanted; also one upon the accompaniment of melody. We refer to Plate V., No. 19, for an example of the mixture of different rhythms in a melody of Paësiello. There is an almost inexhaustible store of melodies, in all their forms, in the works of ancient and modern composers. The student who examines these works will find, that the modern melodists have, in general, little to boast of in originality. To give an instance, one of the most popular vocal compositions in England, *Oh, Happy Fair*, is framed in its commencement, in melody and harmony, upon a church chant of C. P. E. Bach.

Harmony has been defined by an eminent French philosopher of our day, "a succession of chords, subjected to certain laws, according to which several different melodies, governed by a common rhythm, and heard together, produce an agreeable effect to the ear." This definition is, like many other technical ones, unintelligible to every person who has not studied harmony. But we shall make only one objection to it, which is, that very frequently harmony contains little or no melody, properly so called. It must be kept in view that harmony has its own peculiar means of producing effects, independent of melody, or, at least, of any prominent melody. It is more vague in its effects than melody; and, being more complicated, is less generally relished and understood than the latter. A chorus of Handel, or a symphony of Beethoven, requires a trained ear to relish and understand it fully. The progress of both melody and harmony was slow in improvement, as the history of music shows. As the materials of each were increased, like the enrichment of a language, melody and harmony assumed new forms, and became more copious and expressive. To assign limits to what may be called *improvements* in melody or harmony is impossible, since the plastic nature of the human ear is such as to be capable of being trained to relish almost any peculiarities in music, as in the sounds and inflexions of language. When we find that, in ancient times, a rude, unmelodious, ecclesiastical chant, and its accompaniment by another voice in consecutive octaves, fifths, and fourths, were considered as the perfection of melody and harmony, it is hard to say what the human ear may or may not be trained to relish. Gerbert, in his work *De Cantu et Musica Sacra*, gives several specimens of this strange harmony of the fourteenth century. See vol. i. pp. 376, 392, 435, 6, 7, 8, and 456, 7.

But something still more curious than this is given by Franchino Gafforio in the fourteenth chapter of the third book of his work *Practica Musica*, published at Milan in 1496. Under the head "De Contrapuncto Falso," he says that it was anciently the custom to sing a counterpoint composed of dissonances; that is to say, of second major and minor, perfect and major fourth, seventh, and ninth; and that such counterpoint was used in the fourth century in solemn vigils, and in certain masses for the dead. He gives the following example of this horrible counterpoint, as having been sung in the cathedral of Milan, from an ancient mass for the dead. He confesses it to be hideously bad. We avoid the alto clef, for the reader's sake; so the example should be performed an octave lower than it is here written.

Doubtless the human ear was *then* not a different organ from what it is *now*, and yet we should consider such harmony as intolerable. But to many persons the noisy confusion of certain modern compositions for orchestras *and* voices is delightful; voices yelling and growling, and, in the orchestra, all sorts of heterogeneous instruments mingled together to make a chaos of deafening noises. When we find, in a celebrated German orchestra, musical effects attempted to be produced by cracking of whips, firing of pistols, jingling of post-horse bells, ringing of bells of all sorts and sizes, thrumming on the Russian balalaika, beat-

Music.

Music. ing of drums, and so on, and all this received with rapture by a civilized European audience, we may well be justified in saying that it is hard to tell *what* the human ear may or may not be trained to relish in music, or rather in noise. Such music reminds us of the pewter dish, the tongs, the bellows, and the salt-box, used as solo or concerto instruments, according to No. 90 of the Babblers; or of the hog-concert, produced by order of Louis XI. Bayle gives the passage on this subject from Bouchet, *Annales d'Aquitaine*. A great number of hogs of different ages were confined in a tent covered with velvet. In front of the tent there was an apparatus with keys like an organ. These keys communicated with the hogs in the tent, and were armed with needles, so that when the performer touched the keys, the hogs were pricked by the needles, which "les faisoit crier en tel ordre et consonance, que le Roy, et ceulx qui estoient avec luy, y prindrent plaisir."

The opinions of theorists on the subject of chords alone, without reference to their successions and modulations, are very much at variance. Some reckon only one single fundamental chord, formed from the first harmonics of a vibrating string, and which chord, they say, contains all the other chords. Other theorists assume two fundamental chords, others seven, others twelve, others thirteen, others seventy, and so on. Another theorist reckons so many as 3600, and among these, 700 dissonant fundamental chords. Besides all this perplexity and contradiction, these theorists give no satisfactory explanation of a multitude of phenomena belonging to modulation and harmonic combination. We would advise the student to pay very little attention to theories, but a great deal to the works of the best composers. Our space permits us to make only a few occasional remarks upon some received opinions regarding harmony, which seem to us to be erroneous.

Hitherto, what is called thorough bass has been confounded with figured bass; and both, as if one and the same thing, have been ascribed to L. Viadana as their inventor, in the beginning of the seventeenth century. But it appears that Viadana was not the inventor of figured bass, and that his thorough bass (*basso continuo*) has nothing whatever to do with figured bass, or with the doctrine of the progressions of chords. This appears clearly from his Italian work published at Venice in 1603, in five volumes 4to. It contained what he called "a hundred ecclesiastical concertos for one, two, three, and four voices, with the continuous bass (*basso continuo*) to be played on the organ." He says he invented these pieces in 1597, at Rome, and that his chief reason for composing them was, that there were no pieces of the kind constructed for one, two, or three voices, with organ bass. In these concertos, the organ bass had no pauses, and was therefore called *basso continuo*, that is, *continuous* or *thorough bass*; but it was not figured. The organist played this bass, and the voice part, or parts, as they lay before him. G. Sabbatini, a contemporary of Viadana, was the inventor of the *figured bass*, as appears from his work published at Venice in 1628, in which all the basses are figured, and in which he claims this invention. But this invention, which might serve well enough in these days for *slow* and *simple* music, accompanied on the organ according to *certain fixed rules*, has been, unfortunately, brought down to our day, when it is worse than useless, although the teaching and practice of it are still persevered in, to the great disadvantage and perplexity of musical students. Besides, different composers and different nations have different ways of figuring their basses, which adds to the confusion and difficulty. This clumsy contrivance should be entirely abandoned by all modern composers, who ought to write down in the common notation, fully and exactly, the accompaniment as they wish it to be performed.

Music. A chord, as it is called, consists of two, or three, or four, or more sounds, heard at the same time. A primary *consonant* chord consists of intervals such as those given in the following examples, No. 1, A, B, and No. 8, *a*, *b*. Examples of primary *dissonant* chords are given at No. 4, *a*, *c*. Other dissonant chords will be afterwards noticed. The tonic or key-note of every scale may be considered as the central point to which, in the course of a melody, or a harmony, the other sounds of the scale converge, or from which they diverge; in the former case producing tonic cadences or repose, and in the latter, imperfect cadences and inconclusive passages. We have already seen that the sounds of a scale, whether major or minor, may be derived from the harmonic products of three sonorous bodies, representing the tonic, the dominant, and the subdominant. In the scale of C major, for example, the simplest harmony belonging to the tonic, the dominant, and the subdominant, considered as bass sounds, will appear in the three following chords, either as they stand at A, or with a changed position, or inversion, of the two upper sounds in each, as at B.

No. 1.

Subdominant Common Chord.	Tonic Ditto.	Dominant Ditto.	Changed Position.
A.			B.

These chords, as they stand, cannot form a harmonic succession, on account of the consecutive fifths between them. In harmony, as in melody, the intervals are reckoned from the lower sound upwards. Each of these chords is called a major common chord, and consists of lowest or fundamental sound with its major third and perfect fifth. The change of position at B makes no difference in the name of the chord, but only in its effect. The closest possible position of the intervals, as at A, is called *close harmony*. Their altered position at B is called *extended* or *dispersed harmony*. By making the thirds of these chords the bass sounds, we obtain the following inversions, called chords of the sixth. The lowest sound of a chord is the bass for the time being.

No. 2.

Diatonic or chromatic successions of chords of the sixth, with or without the third, are very frequent in harmony. If in each of the preceding common chords we make the fifth the bass, we shall have the following inversions, called chords of the sixth and fourth.

No. 3.

Most writers on harmony consider the interval of the fourth as a dissonance, while in truth it is a consonance, as is clearly shown by its forming one of the intervals in the perfect common chord, which contains no dissonance of any kind. Besides these three principal chords of the major scale, with their inversions, and which are all *consonant*, there is an important *dissonant* chord formed by adding the minor seventh to the fifth and third of the dominant. This is named the *dominant seventh*. We subjoin it (*a*), and its three inversions (*b*).

Music.

Music

No. 4.
Dominant Seventh. First Inversion. Second ditto. Third ditto.

The sounds above the bass, in each of these chords, may be placed in various positions, some of which are shown at (c) and (d). The first inversion of the chord of the dominant seventh is called the chord of the sixth, fifth, and third; the second inversion, sixth, fourth, and third; and the third inversion, sixth, fourth, and second. In parti-

cular circumstances, the second, third, sixth, and seventh sounds of the major scale may each, as a bass, bear a common chord with a minor third. See No. 5 (e), (f), (g), (h), and the inversions i, k, l, m. But harmony of this kind is generally confined to ancient music, or imitations of the ancient style.

No. 5.

The chord at h, with imperfect fifth, is rarely used in what are called *fundamental progressions*.

The chord of the dominant seventh contains two primary dissonances which are the least harsh of any in use, and are therefore the most frequently employed; the interval between the bass sound and its seventh, and the in-

terval between the third of the chord and the seventh; see n, o, p. This last is an imperfect fifth, and requires a particular *resolution* (as it is called) in the next succeeding chord, unless some chromatic alteration intervene to change the simple progression; see q, r, s, t. For the most common resolutions of the seventh, see u, v, w.

No. 6.

A good ear will be displeased by such passages as those at y and z, where the resolutions of the seventh and of the imperfect fifth are neglected.

No. 7. (y) (z)

Such passages are bad, whatever number of Parts there may be besides to fill up the harmony; but they are intolerable when there are only two Parts.

The three principal common chords of the minor scale are the following, at a, b, and c.

No. 8.

Those subordinate ones at d, e, f, and g, may be occasionally used. The same remark applies to them as to the common chords on the second, third, sixth, and seventh sounds of the major scale. Of course, all the common chords in the minor scale may be inverted in the same manner as those in the major scale, thereby producing so many chords of sixth and third, and of sixth and fourth. The positions of their intervals above the bass may also be varied in the same manner as formerly shown.

Sometimes, and especially in ancient harmony, we find a chord of the seventh occurring on every sound of the scale, in what are called *sequences* or *chains* of sevenths, in which the progressions of the bass sounds are by ascending fourths or descending fifths. These dry and formal passages, and their inversions, are now rare. There are some other kinds of sequences still in use; such as the fifth and sixth on each bass sound of a diatonic ascending series, or the seventh and sixth on each bass sound of a descending diatonic series.

No. 9.

No. 10.

Besides these dissonant chords, there are many other dissonant ones, such as the chord of ninth and seventh, or ninth only; the chord of fourth and fifth; and so on.

It is evident that every common chord, or either of its inversions, consists of three distinct sounds only; so that in composing for four voices, for example, a gap would occur in the harmony whenever a common chord, or one of its inversions, had to be employed, unless one of these three sounds should be doubled in the unison or octave. This doubling accordingly takes place when there are more than three Parts in the harmony. Which of these sounds

Music. it is best to double, depends entirely upon the nature of the melodic and harmonic succession of sounds in this or that particular passage, and cannot be rightly learned but by a careful study of the best compositions in four, five, six, and more Parts. The chord of the seventh, again, or any of its inversions, consists of four distinct sounds, and therefore requires no doubling of any of its sounds in writing for four Parts. In other cases where the Parts are more than four, the doubling of any of the sounds (except the third, or the seventh of the primary chord) must be regulated by the circumstances of the case. The third and the seventh of the dominant chord of seventh do not bear to be doubled, because the progression of each of these sounds follows a certain course in *resolution* by the third rising a semitone and the seventh falling a semitone, or a tone, into the next succeeding chord, unless in the case of some chromatic alteration which interferes with the simpler progressions of these two sounds. In writing for three or for two Parts, it becomes necessary to omit one or two of the sounds belonging to the chord of seventh,

or any of its inversions. Whether the third or the fifth of the primary chord should be retained along with the seventh, depends upon the effect intended to be produced. In the former case the effect will be more piquant, in the latter more soft and undecided. Again, in writing for two Parts, suppose a duett for two voices, it is necessary to use only two of the sounds of a common chord, or two of the sounds of a chord of seventh. In the former case none of the sounds ought to be doubled, except at the beginning, or at a close, or in preparing a cadence, when the unison or octave of the lowest sound of the primary chord, or of its fifth, may be used. In the other case (chord of seventh) there is a choice among the intervals of primary sound and seventh, third and seventh, or fifth and seventh, or the inversions of these. The effect intended must guide the choice. In these cases none of the sounds should be doubled in unison or octave.

What are called the *preparation*, the *percussion*, and the *resolution* of dissonances, may be made sufficiently clear by the following examples of Padre Martini.

No. 12. No. 13.

(a) (b) (c) (d) (e) (f) (g) (h)

At No. 12, (a), the seventh is *prepared* by the previous consonance of sixth, and is *resolved* upon the consonance of third. At (b) the ninth is prepared by the previous consonance of tenth, and is resolved upon the consonance of fifth. At (c) the sevenths are both prepared by previous fifths, and resolved by the consonances of fifth in the first case, and third in the second case. At (d) the second is prepared by third, and at (e) by sixth, in the preceding chord.

At No. 13, (g), the ninth and eleventh are *prepared* by previous tenth and twelfth, and are *resolved* into eighth and tenth. At (h) the ninth and seventh are prepared by previous tenth and eighth, and are resolved into eighth and sixth. As to what is called the *percussion*, or *striking* of the

dissonance, it means simply the actual occurrence of the latter. The dissonance of the dominant seventh has no need of preparation; and the diminished seventh, the ninth, and the diminished ninth, are often struck unpre-

pared. The chord of the ninth, , and of the di-

minished ninth, , are susceptible of three inver-

sions. These, with their resolutions, are as follows:.

No. 14.

In the chord of the ninth, and in its inversions, the sound forming the fifth in the direct chord is generally omitted. The ninth itself is not inverted, and care must be taken to keep the ninth in its proper interval above the lowest sound

of the direct chord, so as to form a ninth or higher octave of ninth above that sound. The following infractions of this rule produce in general a bad effect, especially when prolonged.

No. 15.

The ninth may be used in the following manner, without any preparation:

No. 16.

In Haydn's beautiful canzonet, *Fidelity*, there are examples of the use of the major seventh, the ninth, and the diminished ninth, all without preparation. In the same canzonet we find the augmented octave and augmented

fifth employed very elegantly. His tenth canzonet shows a very effective use of the diminished seventh, at the word "grief;" and also, at the same passage, the skilful introduction of an interrupted cadence. In the second section of the first movement of Mozart's third quintett in G minor there are many diminished ninths, and ninths and sevenths, introduced very boldly without any preparation. In Italy; about 1580, Monteverde began to introduce *unprepared* sevenths and ninths; but it would appear, from the following very curious passage, that Jean Mouton, a Frenchman, had used these *unprepared* dissonances long before. J. Mouton was born in 1461.

Music.

Examples of Unprepared Sevenths and Ninths, and of both combined, about the end of the Fifteenth or beginning of the Sixteenth Century.

Music.

No. 17. Jean Mouton.

It is worth while to remark, that, in dissonant chords, the dissonance often leaves its place and passes to some other sound of the chord, without being resolved in the

way it would have been had it continued to keep its place. For example:

No. 18.

Passages of this kind often puzzle the student, as seeming to contradict the rules given for the resolution of dissonances.

In a series of chords, the progression from one to another may take place by similar motion, oblique motion, or contrary motion. The latter is the most frequent and the most useful, as it gives greater variety to the harmony, and enables us to avoid displeasing consecutions of octaves and fifths.

In similar motion, the Parts move together by conjunct or disjunct degrees, ascending or descending.

In oblique motion, one of the Parts remains on the same degree, while the other moves upwards or downwards.

In contrary motion, the Parts move in opposite directions; the one ascending, the other descending.

No. 19.

Similar Motion. Oblique Motion. Contrary Motion.

Chords in succession.

An examination of all the possible successions of chords, consonant and dissonant, direct or inverted, diatonic or chromatic, is beyond our limits and our purpose. These successions must be learned from an extensive perusal of the best compositions. We must confine ourselves to a few examples and a few general remarks. First, with regard to common chords in succession, two or more of them are not allowed to succeed each other diatonically, or by leaps in similar progression, or what is called *similar motion* ascending or descending.

No. 20.

The bad effect of such progressions is much more striking in compositions for voices, or for different instruments, than it is upon such an instrument as the piano-forte, on which the progressions of the different parts are not so distinctly perceived by the ear, owing to the quality of tone or *timbre* of each sound being of the same kind. It ought

to be remarked, that this last circumstance is too much neglected in writing for the organ or the piano-forte, and that in consequence many particular passages of harmony written for one of these instruments produce little or no effect, or even a bad effect, while the same passages, if performed by different voices or different instruments, would be good and effective. In the above successions of common chords (No. 20) there are consecutive fifths and octaves, both of which, and especially the former, are prohibited in all cases where *the ear perceives them* and is displeased by them. There is no other rational rule against their use. With regard to consecutive unisons or octaves, daily experience proves that they are not in themselves displeasing when they are employed in the reinforcing of some particular melody or passage of melody. Were this not so, there would be no such thing in choruses or in orchestras as ten, or twenty, or more voices or instruments, performing the same melody in unison or in octaves. Haydn said that one of the most overpowering effects he ever experienced from music, was when he heard the singing of the subjoined melody in unison by a vast number of trained children in St Paul's Cathedral at London.

In a composition for two, or three, or four voices or instruments, where the intention is to interest by means of harmony, the *casual* occurrence of consecutive octaves is felt unpleasantly from the poorness of their effect, from the deficiency of that richness of harmonic combination generally expected in such compositions; but still only a *musical* and *trained* ear would perceive this poverty of effect, and be displeased by it. The fewer the number of Parts, down to the duett, the more perceptible would this poverty be. The bad effect of consecutive fifths also rests upon the ground of poverty and want of variety. Some modern theorists assert that the *reason* why two or more consecutive fifths produce a bad effect, is, that the ear supplies the major third of the lower sound of each fifth, and thereby perceives a succession of major common chords forming so many disjointed tonic chords, which give an impression of a series of different keys unrelated to each other. This hypothesis is erroneous, because the ear does really supply no such thirds, nor any other sounds. The ear, in harmony as well as in melody, supplies nothing beyond what it actually hears. It has to do with nothing but its own actual sensations. The *imagination* may supply or suggest what it pleases; but that is quite a different matter. Cherubini says of consecutive fifths, that "a succession of them forms a discordance, because the upper part moves in one key, while the lower part moves

in another. For example, if to the scale of C major we add an upper Part moving in perfect fifths with the former, it will result from this, that one Part will be in C, while the other will be in G. It is from this double concurrence of key that the discordance arises, and consequently the prohibition to employ several fifths in succession." The best way to avoid the effect of consecutive fifths and octaves, is to employ contrary motion of the Parts. The second examples (No. 22) should never be used in music for two Parts only, or between two extreme Parts of a harmony, though they may be used in two middle Parts between the bass and the highest Part where the harmony is full.

No. 22.

We have seen that the three principal common chords of a scale are those of the tonic, the dominant, and the subdominant; and that the principal dissonant chord is the chord of the dominant seventh. We shall first examine these common chords in their simple diatonic successions, direct and inverted; and afterwards as undergoing certain chromatic changes, and other modifications. The letter T will stand for tonic chord, D for dominant chord, and S for subdominant chord.

No. 23.

At *a* and *b* and *c* we have three progressions from T to D producing three imperfect cadences (see preceding section, *Melody*) of harmony and melody together. At *d*, *e*, and *f*, we have three other progressions from T to S, producing also imperfect cadences, but not so decidedly imperfect as those at *a*, *b*, and *c*. Indeed these last might, not improperly, be called *reversed* cadences. At *g*, *h*, *i*, we have three progressions the reverse of *a*, *b*, and *c*, and forming tonic cadences more or less complete. At *g*, the cadence is complete, from the third of dominant rising semitonically, in the upper Part, to the tonic itself. The cadence at *h* is less complete, from the fifth of dominant descending to tonic by a whole tone in the upper part; and at *i* the cadence is still less conclusive by the fifth of

dominant rising by a whole tone to the third of dominant. At *g* and *h*, if the dissonance of seventh were added to the dominant, the determination of the complete cadence from D to T would be more striking.

No. 24.

A perfect cadence from the chord of the dominant seventh may be *interrupted* in various ways. The following are examples.

No. 25.

The successions at *k* and *m*, No. 23, may be considered as imperfect cadences, although in some cases, in ecclesiastical harmony, the cadence from the chord of the S to the chord of the T is used as a final cadence. The succession at *l* is an imperfect cadence, the most imperfect that occurs in the scale, if we except *n* and *o*.

The succession at *n* from S to D is used in ancient and modern music; but the contrary succession at *o*, from D to S, is very rarely attempted, on account of its harshness and striking discontinuity. No satisfactory reason has

been assigned (theoretically) for the avoidance of such successions; nor why the progressions of common chords (properly managed) between the tonic and its second, ascending or descending by conjoint degrees, or between the dominant and the sixth of the scale, ascending or descending by conjoint degrees, should be frequently used with no displeasing effect. And, again, what *fundamental bass* can be assigned, according to received theories, to such successions as chords of sixth and third ascending or descending by conjoint degrees? Not to speak of many

Music. more successions in harmony and in melody, quite inexplicable by the system of fundamental basses, commonly received as the true one. It may be remarked, that singers, in attempting to sing the ascending major scale, always find great difficulty at first in executing, in tune, the series of sounds from the fourth upwards to the seventh.

No. 26.

This is a practical fact, not explained by any theory. If you give the learner (with a

No. 28.

a b c d e f g h i k l m n

No. 29.

At *b* the progression *might* be ; but such a

passage is harsh in its effect, from the more natural progression of the third of the dominant being by a semitone ascending, instead of by a leap. Another harsh progression

No. 30.

might be (according to some composers) in-

troduced at *b*. But such progressions ought in general to be avoided, though they sometimes occur in the free style of modern music; not, however, in the works of the best masters. It may be here remarked, that although the perfect fourth is a consonance, as we have said before, still, when it occurs between the bass and an upper Part, it requires a certain management. This is the reason why it has been erroneously called a *dissonance*. It would require a great many examples to show in what manner the perfect fourth should be treated when it occurs between the bass and an upper Part. We shall merely remark,

No. 31.

that, except in such successions as , &c.

the fourth must, in general, descend by a semitone, or a tone, to the third of the same bass sound; or, if the bass moves upwards or downwards to the following chord by a tone or a semitone, the sound forming the original fourth must either be continued in that following chord, or must descend a semitone or a whole tone. Such are the technicalities regarding the treatment of the fourth in harmony. The quantity of printed disputation regarding the nature, &c. of the fourth is most unreasonable.

A great deal of the variety and *colouring*, as it is called, of the free style of modern music depends upon the use of chromatic changes of the intervals of the simple common chords, and their inversions. To make the nature of

No. 33.

good ear) three of the ancient conjunct Greek tetrachords **Music.** to sing in ascending, there is no difficulty in the intonation.

No. 27.

The ancient Greeks seem to have known more about fragmentary scales than our modern theorists do.

The partial inversions of the preceding successions of common chords are as follows:

this more clear, we shall again have recourse, in the first place, to the same successions of common chords that we have already given, and show how their forms and effects can be altered by means of these chromatic changes. Of course, it is not upon every occasion that these chromatic changes are to be used. Some clever composers of the more modern schools indulge in these chromatic alterations to such excess that many of their compositions are little better than continuous lamentation, or caterwauling. By such abuses, the manly simplicity, energy, and dignity of certain styles of music are entirely destroyed. The whole practical principle of these chromatic changes is the division of a tone into two smaller intervals, ascending or descending. We do not say "into two *semitones*," because that is not really the case in correct intonation of such passages. In a succession of chords such as we have given, one at least of the Parts may rise or fall by a tone to one of the Parts of the next succeeding chord. It is therefore obvious that an ascending or descending tone *may* be divided into two smaller intervals; and this is done by the chromatic alteration,—sharp in ascending, and flat in descending, as shown in Plate VI., Nos. 20 to 27 inclusive. We give these merely to show how the thing may be done. *When* such chromatic alterations may be introduced with good effect, is to be studied in the compositions of Hadyn, Mozart, Clementi, Beethoven, and some others. All our examples of mere chords are to be considered by the student as no more than some of the dry and detached bones of a skeleton of harmony. He will find them all knitted together in their proper places, and clothed in living beauty of form and substance in the works of the best composers. It is *there* that he must seek for their use, and not in theories.

False relations must be avoided in melody as well as in False relation. When a sound passes to its diminished or augmented octave, above or below, there is a false relation in melody; as,

No. 32.

In harmony, such octaves struck together, and *prolonged for some time*, would be intolerable. Such passages as the following contain false relations.

Music. In these passages, the chromatic alteration is not made in the same Part; hence arise the false relations, and their harsh effect. These examples, when corrected, will stand as follows:— Music.

No. 34.

Such passages as the following, where dissonances occur along with the chromatic alteration, are not objectionable.

No. 35.

Such as the following are permitted.

No. 36.

Dr Burney, in criticising some of Purcell's harmonic combinations, blames him severely for using the $\flat 6$ and $\sharp 3$

No. 37.

and says that this chord is "*detestable*,"

and is "jargon at all times and in all places." It so happens that this same *detestable* chord is very frequently used in modern music; and, if Dr Burney had looked into the works of Emanuel Bach and Haydn, of which he speaks with unmingled commendation, he would there

have found many instances of the elegant and effective use of the chord of $\flat 6$ and $\sharp 3$; also in Mozart's works, both vocal and instrumental. Another chord that Dr Burney finds great fault with in Purcell, is the chord of

No. 38.

but this chord is found in the works of the best modern composers. Among chromatic chords we shall notice only two more, of considerable importance, which frequently occur in harmony. They are the chord of the diminished seventh, and the chord of the augmented sixth.

No. 39.

Diminished Seventh,

Inversions,

Augmented Sixth.

These chords occur more frequently in minor scales than in major ones; and when they do appear in the latter, the notation is generally wrong. For example,

No. 40.

Instead of

The effect of the diminished seventh is mournful and pathetic. Among other instances, see "He was despised," in Handel's *Messiah*, at the words "a man of sorrows." Sometimes we meet with a series of three or four chords of diminished seventh, or their inversions, in which all the Parts ascend or descend together by semitones. With regard to the chord of the augmented sixth, it is called

No. 41.

the Italian sixth when it consists of $\sharp 6$

the

No. 42.

German sixth when it consists of $\sharp 6$

and its third.

When in this position

No. 45.

we can-

No. 43. the French sixth when it consists of $\sharp 6$

Of

these, the Italian sixth is the most simple and elegant, and the German sixth the most powerful in its effect. The French sixth is harsh and poor. In writing for four Parts, the third of the Italian sixth is doubled:

No. 44.

The third and fifth of the German sixth

are usually prolonged in the form of $\flat 6$ upon the next bass sound; but there are some exceptions to this practice. These augmented sixths are rarely inverted; but some instances are to be found in good composition. In the chord of the diminished seventh, it depends upon the position of the upper Parts, whether or not we may double

Music. not; but we may in the following position, where the diminished seventh occurs in a middle Part, and below the

No. 46.

We have a few remarks to make

upon what are called enharmonic changes of modulation, made by means of the chord of the diminished seventh, or of the chord of the German augmented sixth, or inversions of these. What is termed *enharmonic*, is really neither more nor less, in practice, than a change of signs in notation; which change, being merely addressed to the eye in all such pretended enharmonic transitions, leaves the sounds exactly as they were before upon all our imperfectly-tuned instruments, such as the organ and piano-forte. For example, we strike the following chord on a

No. 47.

If we choose to alter the signs

No. 48.

No. 49.

of this chord, and to write

No. 50.

, all this makes no change whatever in the

sounds heard on the piano-forte. The very same sounds are produced, because the very same finger-keys are struck.

No. 51.

In the case of the German augmented sixth

No. 54.

At 1 we have a single suspension, that of the fourth; and at 2, a double suspension of sixth and fourth. These are two of the cases formerly alluded to, in which the perfect fourth, though a consonance, is treated as if it were a dissonance when it occurs between the bass and an upper Part. At 3 occurs a single suspension, a major seventh ascending a semitone to its resolution in the octave; at 4, a single suspension of ninth resolving *downwards*, as the ninth almost always does, by descending a tone or a smaller interval, according to the nature of the passage in which it occurs; at 5, a double suspension of ninth and major seventh, in which the ninth is resolved by ascending a tone, and the seventh by ascending a semitone; at 6, a double suspension of ninth and fourth; at 7, a triple suspension of ninth, sixth, and fourth; at 8, a quadruple suspension of ninth, seventh, sixth, and fourth. Such combinations of dissonances as this last are not frequent; but they sometimes occur in the best instrumental

No. 52.

we might change the notation into

the sounds would remain the same on the piano-forte; so that the real differences between the sounds represented by these different modes of notation, cannot be made by such an instrument as the piano-forte, and therefore all pretended enharmonic changes and modulations upon it are mere delusions and non-existences. Again, to take a very plain case: Suppose that we were playing on the piano-forte a passage written in Eb, and that we chose to change the notation suddenly to D#, where would be the enharmonic *modulation* in such a case?

No. 53.

There is not the slightest difference of effect. A *real* enharmonic change in such a passage, if effected by voices or instruments in perfect intonation, would produce a very perceptible difference of pitch, and no agreeable result.

In passing from one chord to another, one or more of the parts of the first chord will (in compact harmony) ascend or descend by a tone, or a smaller interval, to one or more of the parts of the next chord that follows. The *prolongation* of one or more of these ascending or descending parts of the first chord, after one or more of the parts of the second chord has been introduced, gives rise to a variety of dissonances termed *suspensions*, or *syncopations*, and so on. These may be single, or double, or triple, or even quadruple. In order to make the nature of this part of our subject intelligible, but without entering into many details, we shall again have recourse to the successions of common chords already given in this section, and also to the chords of seventh, and of diminished seventh, and of diminished ninth.

compositions. This *legato* and *syncopated* style belongs more to the old schools of composition than to the modern. The effect of such passages is good on the organ as an accompanying instrument, or as a principal instrument, on account of its powers of producing the *sostenuto* and the *legato*; but is almost null on such an instrument as the piano-forte, from its deficiency in these powers of *sostenuto* and *legato*. Voices and wind-instruments produce great effects in this style of music. It is not so effective in music for stringed instruments. Besides a great variety of suspensions that may take place in an upper Part, there are many that may occur in the bass when its progression is by conjunct degrees ascending or descending. Of the following examples, 1 and 2 are the best, though 3 and 4 are from Beethoven. These last may be used in cases where the combinations of different voices or instruments are suitably arranged, or in the course of a rapid movement.

Music

No. 55.

The nature of what are called *anticipations* (the converse of *suspensions* or *retardations*) will be understood from the following examples.

Music.

No. 56.

At 1 the anticipations are in an upper part; at 2 they are in the bass. Anticipations such as those at 3 are frequent in music of the time of Handel, and before then.

We give a few examples of what are called *passing*

notes, *changing* notes, *transient* notes, &c. which (as well as suspensions and anticipations), are said by theorists to be *unessential* or *accidental* notes.

No. 57.

These so called *passing* notes are marked with a small zero. It is needless to multiply examples here, and we shall only refer to one remarkable instance of the use of *passing* notes, which occurs at the beginning of the first movement of the first quartett in Beethoven's fifty-ninth work. The violoncello begins with a fine and dignified subject (key F

major), accompanied by the viola and second violin, in the

No. 58.

following manner for six bars and a half, when the harmony changes.

No. 59.

The first violin comes in at the ninth bar, imitating the preceding passage of the violoncello, and accompanied by the three other instruments forming the chord of the second inversion of dominant seventh, as far as the seventeenth bar, where the following bold passage occurs.

No. 60.

With regard to *passing* notes, notes of *grace*, *anticipations*, *substitutions*, *altered* or *chromatic* notes, and so on, the truth seems to be, that theorists have always found them inexplicable upon their favourite principle of the fundamental bass; and that, not knowing how to account for them rationally upon that principle, they have been obliged to treat all such sounds that occur in melody and in harmony as sounds that have no foundation in the *real* structure of the composition; and to assign to them, by way of salvo, any names that might pass current in an obscure and erroneous terminology. But if theorists *will* adhere to the received systems of fundamental basses, they ought to be able to apply these systems to *all* the phenomena of melody and harmony. This is not the case; for it is utterly impossible to refer *all* the combinations of modern (or even of ancient) harmony, to the received systems of fundamental basses. Every candid and intelli-

gent musician will admit this to be true. Among all the systems of fundamental basses, Serre's theory (formerly alluded to) seems the most plausible, although still very imperfect. He assigns to a chord, one, or two, or three fundamentals, which are to correspond to the diatonic or chromatic nature of the sounds and intervals of the chord. But other theorists have their fundamental *suppositions* and *substitutions*; their *after* notes; their *changing* notes; their *passing* notes; their *altered* notes; their *appoggiature*; their *suspensions*; their *anticipations*; and, in short, such a chaos of hypothetically unessential and *unreal* things, that it is no wonder if the study of harmony is looked upon with horror and despair by all students who are trained in the ordinary schools of composition. They meet, at every step, with contradictions as absurd and perplexing as the long established algebraical dogma that there are *quantities less than nothing*. A little common sense and logic might have shown that this puzzling dogma is a mere contradiction in terms. *Nothing* being *no quantity* at all, it is obvious that there can be no such thing as a *quantity less than nothing*, or even *equal to nothing*. If such absurd contradictions in terms pass so long current in the most severe and exact of all sciences—*mathematics*—it cannot surprise any thinking man that musical theories and systems should abound in similar ones.

It is wrong to say that the *ear* recognises or suggests what are called *suppositions* and *substitutions* in fundamental basses; sounds that are not heard, but are ascribed, by erroneous theory, to such and such chords. The ear hears none of these imaginary and hypothetical things. Were it otherwise, and to carry this hypothesis to the *reductio ad absurdum*, the ear ought to hear all the chords that can possibly be applied to the accompaniment of any given melody. In fact, if two voices, or two instruments, perform a duett, for example, the lower Part is

Music. felt to be the bass for the time being; and there is no other Part felt, or *supposed*, or *substituted*, by the ear. The imagination may suggest an additional Part below the lower Part, or above the higher Part, or intermediate; but this has nothing to do with the theory of the fundamental bass. If another lower Part is added to this same duett, then the ear feels *that* Part to be the bass; and supposing a fourth or a fifth Part, and so on, added still lower, then such added Part becomes the bass, in so far as the ear is concerned. If the lowest Part is overpowered by the upper ones, then the ear pays no attention to it, but to the predominant upper or middle Part or Parts. Experiment will prove this. If a melody is performed by a single voice or instrument, or by a great number of voices or instruments in unison or in octaves, does the ear supply a fundamental bass, or any bass at all? Surely not. As to what are called *passing* notes, chromatically *altered* notes, *suspensions*, *anticipations*, and so on, in melody or harmony; all these *sounds* are just as *real* as any other sounds that are heard in the course of the melody or of the harmony; and if theorists adhere to the received fundamental bass system, then *every* sound that is heard in a melody, or in any Part of a harmony, must have its own fundamental bass, just as much as *any other* sound that exists in the melody or the harmony. This inference is inevitable from rational logic. One of the most absurd hypotheses in musical theories is found in the attempt to explain, according to the fundamental bass system, a series of chords of 6th and 3d ascending or descending by conjunct degrees. It is said that in such passages there is an *ellipsis* of a chord between every two chords of the series, and that the ear understands this to be the case, and supplies the omitted chords!

When musical theorists meet with passages that cannot be explained by the hypotheses advanced, such passages are called *licences*. Unfortunately these *licences* are so numerous in music, that the rules are overwhelmed by exceptions. The easy way for a puzzled system-monger to escape from the difficulties that beset him is, no doubt, to have recourse to such convenient words as *licences*, *exceptions*, and so on, which are not unwillingly received by the public as substitutes for truth. In the works of the greatest composers are found many passages of excellent effect, though prohibited by the rules of theorists. Such being the case, we would again earnestly urge the student to form an extensive acquaintance with the best models of the art, rather than trust to any theories on the subject. He ought never to give up his reason and his feelings to any theoretical authorities. If he do, he will become timid and uncertain. Every thing he meets with different from what his dry rules have taught him, will perplex and terrify him. His energies will be paralyzed, and he will be incapable of producing any thing but cold, feeble, and formal music. To escape this result, he must take a comprehensive view of the art and its accessories; devote himself to no particular composer or school of composition; study the best music of every kind and of every country; and not allow himself to be captured and manacled by any theorist. He ought to keep in view that, in music, nothing is out of rule except what offends the ear, the taste, and the judgment; but that he must not venture to imitate the freedom and the bold effects of the greatest masters, until he has acquired great knowledge and command of the materials of the art. This cannot be acquired but by a well-directed course of study. Young painters are generally ambitious of handling the brush and colours before they have learned to draw correctly with a pencil or a crayon. If they are permitted to follow this course, they never attain eminence in their art. The case of the impatient musical student is analogous. Before he has learned to write correct melody, or correct

VOL. XV.

harmony for two voices or two instruments, he burns to signalize himself by writing a chorus or a symphony, an opera or an oratorio. The lamentable failure of such a premature attempt disgusts and disheartens him. He abandons study as hopeless; and, if a man of genius, deprives the world of an excellent composer by neglect of the old maxim, *festina lente*. It is well to remark here, that Haydn, in the height of his reputation, declared to his friends that he did not recollect having passed a day without working sixteen and sometimes eighteen hours. We may also remark, that Haydn formed his own admirable style by the indefatigable study of every good composition within his reach; by neglecting no opportunity of gaining information regarding his art; and by forming for himself his own theory and principles of musical composition. In the earlier part of his life he studied intently the works of C. P. E. Bach, a musician of the highest order of genius, and also the works of G. B. San Martini of Milan, a composer of great genius and originality, but not possessed of patience enough to cultivate his abilities to the uttermost. In Haydn's earlier works, among others, some of his Sonatas, the resemblance between his style and that of Emanuel Bach is most striking. Indeed, the two styles are hardly distinguishable. But, as his musical horizon extended, he saw that neither E. Bach, nor John Sebastian Bach the father, nor G. B. San Martini, nor many more whom he studied and imitated, would suffice to make him a great and original composer. So he applied himself to the improvement of instrumental music, and to the invention of a new style of composition in instrumental quartets and symphonies. His best quartets and symphonies still remain unrivalled, for the admirable management of the subjects and modulations, the judicious employment of the different instruments, the unity of design in each movement, and the clearness of construction and of harmony. Haydn was a great advocate for melody. He used to say, "Every composition that has a fine melody is sure to please;" and experience proves the truth of Haydn's assertion. He was of opinion that the most *recherché* and learned harmony without melody was only an elaborate noise, which, if it did not displease the ear, excited neither the feelings nor the imagination. We shall close this part of our subject with a few remarks that may be useful to the student.

The practice of composition ought to begin with melody for a single voice, with or without a bass Part. The next step is to learn to write correctly for two voices, then for three, then for four, and so on. The custom of writing for voices will induce a habit of correctness not to be acquired by persons who begin by writing for instruments.

The proper manner of accompanying vocal music forms a difficult branch of the art, and cannot be studied with advantage till considerable skill has been acquired in vocal composition. The compass and quality (*timbre*) and powers of different instruments, and their effects in combination, must now occupy the student's attention. He ought to take every opportunity of hearing good instrumental music well performed, not only by orchestras, but also by military bands; and of observing attentively the various effects produced. In whatever he composes, clearness of harmony ought to be carefully preserved. Obscurity of harmony arises from the following causes: Too rapid a succession of sounds, chords, and keys; a complication of different movements that take place simultaneously in the different Parts, especially when these movements are at the same time accompanied by a series of chords that succeed each other very quickly, or by sudden modulations. Two different movements at the same time, unite easily; three not so easily; four may produce obscurity, if they are not very skilfully arranged, and especially if care is not taken, at the same time, that the chords do not suc-

Music.

Music. ceed each other, but at the distance of a bar at least. More than four different movements at once almost inevitably produce confusion. It is therefore mere waste of time to attempt to give a different movement to each of the Parts of an orchestra. Harmony for three, and especially for two Parts, is much less liable to become confused than harmony for more than three Parts. For this reason, harmony in two or three Parts should be frequently used, particularly in music written for the public. Besides clearness of harmony, there is another kind of clearness not less important. It depends on the choice of ideas, and the order in which they are connected. Wherever there is neither *unity of ideas*, nor *proportion*, nor *symmetry*, there is confusion.

That excellent composer Piccini, the rival of Gluck and of Sacchini, occasionally employed full and rich harmony in his orchestra, but disapproved of the common practice of keeping all the instruments continually busy. He wished to make the voice the principal Part in his operas, and that the instruments should only sustain the voice, or express what was indicated by the words, or by the action of the persons of the drama, or by the place and circumstances of the scene. He was opposed to those *disegni ostinati* in the accompaniment, which Jomelli brought into fashion, and which are uniformly prolonged through nearly the whole extent of a piece of music, although the words present shades of feeling or ideas which would require corresponding shades in the accompaniment. Multitudes of different instruments, continual orchestral effects, crude masses of harmony, and a perpetual affectation of dissonances, were considered by him as musical monstrosities. He said, "It is not difficult to know what can be put into a harmony. The difficulty lies in knowing what should be left out. The four Parts for stringed instruments, which form the basis of the orchestra, lend themselves almost equally to every kind of expression. This is not the case with the wind instruments, and instruments of percussion. The expression of the oboe differs from that of the clarinet, and that of the clarinet very much from that of the flute. The horns change their expression according to the key in which they are used. The bassoon, whenever it is not confounded with the bass, becomes sad and melancholy. The trombones can express nothing that is not lugubrious. The trumpet, nothing that is not warlike and brilliant. The kettle-drum is altogether military. If each of these instruments were reserved for its proper employment, we should produce varied effects, succeed in describing every thing, and continually diversify our musical pictures. But we are lavish of all these means, all at once, and always. We exhaust and harden the ear. I should like to know what we shall do to awaken it when, as will soon happen, it will be accustomed to this uproar. What new *diablerie* shall we contrive? Perhaps we shall then wish to return to nature, and to the true means acknowledged by art; but you know what happens to persons accustomed to drink brandy." Some combinations of harmony, and treatments of dissonances, &c. not explicable by common theories, will be found in Plates VI., VII., Nos. 28 to 71.

Modulation.

We mentioned, in the section on Melody, that a treatise on melodic modulation is wanted; and we think that a satisfactory treatise on the modulation of harmony is also a desideratum. But neither can be written to any good purpose in the present state of the theory of music,

taking the word theory in its most comprehensive sense, as applied to this art. Philosophers seldom understand music; and the greatest practical musicians have neither leisure nor inclination to attempt to analyse its nature; so that, for want of properly conducted investigation, we are likely to remain in the same "*aere senza stelle*" which at present darkens the depths of the art.

Modulation signifies, properly, the regular constitution of melody and of harmony in any given key, but is *commonly* used to express the art of conducting a melody or a harmony from one key into another, or through several successive keys. This change of key might be more properly called *transition*. Many persons believe that there can be no modulation where there is no change of key. But this is an error, since modulation takes place even in the simplest melody confined to one key. Transition is only one kind of modulation, and is worthless if injudiciously employed. We may make a transition from one key to another suddenly, and without any intermediate sounds; or by means of one or more intermediate chords through which we modulate into the new key.

The art of good modulation from one key to another, consists in the choice of these intermediate chords, and in their relative durations. The use of sudden transitions from one key to another, without any intermediate chords, requires attention to a variety of circumstances, in order to produce a good effect. Such transitions should be but sparingly employed in any regular composition. Every regular piece of music is composed in a particular key, in which it begins and ends, and which generally predominates over all the other keys that may happen to be introduced in the course of the piece. If the key is major, what are called its relative keys will be two major ones and three minor. If a minor key, its relative keys will be three major ones and two minor. The following tables will show what these relatives are:—

C major, principal key.	A minor, principal key.
D minor, first relative key.	C major, first relative key.
E minor, second relative key.	D minor, second relative key.
F major, third relative key.	E minor, third relative key.
G major, fourth relative key.	F major, fourth relative key.
A minor, fifth relative key.	G major, fifth relative key.

These six keys offer, in their modulated connection, 720 combinations. The nearest related keys to a major key, taken as principal, and into either of which it may easily pass without any intermediate chord, are its dominant, its subdominant, and its sixth; thus, from C major to G major, or to F major, or to A minor.

The keys most nearly related to a minor key, are its third below or above, or its dominant, or its subdominant. It may pass into any one of these without an intermediate chord; thus, from A minor to F major, or to C major, or to E minor, or to D minor. In such cases we do not properly modulate, but make a sudden transition into a new key. In the following examples, we modulate by an intermediate chord:

No. 1.

C into G. C into F. C into A.

Music. The general rule is, that we can *modulate* into a *relative* key by means of one single intermediate chord, which chord is the dominant seventh, or some inversion of the dominant seventh, of that relative key. We may remain in the new key for some time, or we may quit it immediately, and modulate into a third key, and so on. An example of rapid modulation from key to key by means

No. 2.

Not unfrequently we meet with modulations into relative keys brought about by means of an intermediate common chord. For example:

No. 3.

In passing from one key to another, a third, a fourth, or a fifth below, without using any intermediate chord, it is proper to keep in view the following remarks:—1. Transition to third below. In this case, if the former key is major, the second should be minor. For example, C major, A minor. Here the transition is to the minor third below. A bolder and more unusual transition is from one major key to another major key, a major third below;

No. 4.

In the case of a transition from one key to another a minor third above it, the first key must be minor and the second major; for instance, from A minor to C major. This kind of transition is found in certain short pieces of music, and, among others, in some Russian airs. Another transition (if so it may be called) which is not unfrequent, occurs when we change the mode without changing the key; for example, when we change C major into C minor, or the converse. We may pass immediately from a major key into a minor key its fifth below; for example, from C major into F minor. Again, after making a cadence upon the dominant of a minor key, we may proceed immediately to the key of the major third below that dominant, or to the key of the minor second above that dominant. For example, from dominant common chord of C minor, we may make a transition into the key of E-flat major, or of A-flat major. Of the former kind of transition a very beautiful example occurs in the *Adagio sostenuto* in Haydn's second quartett, Op. 16, where, from the dominant common chord of C minor, the change of key is made into E-flat major. Also another in the "*Hodie merum*" of Haydn's "Seven last Words of the Passion," at the 21st measure of the movement. In the same movement, at the beginning of its second section, a very effective modulation occurs from E-flat major into F minor, by means of the following passage.

No. 5.

of intermediate dominant sevenths, or their inversions, occurs in what is called the "Tour du Clavier," or harmonic circle of keys. It is needless to give more of this than a fragment by way of example, since long successions of the kind are not used in modern music. Only short passages of such modulation occur in the best modern compositions.

Music.

such as from C major to A-flat major. If the first key is minor, the second key should be major. Thus, from C minor to A-flat major, a major third below. 2. Transition to the fourth below. The two keys ought to be both minor or both major, otherwise they will not be relative. 3. Transition to fifth below. The two keys ought to be both major or both minor, for the same reason that has just been given. To make a real change of key without intermediate chords, we must introduce at least one entire phrase or period in the new key. (See *Melody*, for *phrase* and *period*.) Thus, after a subject in C major, we might introduce a period in G major, in F major, or in A minor, and afterwards return to the key of the subject. Sometimes, but much more rarely, a transition is made from a given key to another a major second or a minor third above it.

The following is an instance of the first kind of transition just mentioned.

Examples of transition from the dominant common chord of a minor key, to a major key a minor second above that dominant, as at No. 6 below, may be found in the works of Haydn, Mozart, Beethoven, and other composers. An instance may be seen in the Finale to Haydn's Symphony, No. 5 (about the middle of the movement), where the transition is from dominant of F-sharp minor to the key of D major. In the "Trio" of the first quartett in Beethoven's Op. 18 there is an example of a transition from the dominant of F major into the key of D-flat major. In the sixth measure of the first movement of Beethoven's quartett, Op. 95, we find a very singular transition from the dominant of the key of F minor into the key of G-flat major.

No. 6.

In the *allegretto vivace* $\frac{3}{8}$ in the first quartett of Beethoven's Op. 59, there are some curious transitions. Near the beginning there is a transition from the dominant of B-flat major to the key of A-flat major, and from the dominant of this last key a transition to the key of C-flat major. Sometimes, in order to produce a powerful effect of contrast, a transition takes place directly from the tonic of a major key to the major key a semitone above, or a major third below. For example, from C major to D-flat major, or to A-flat major.

Music.

No. 8.

Music.

At the beginning of the second part of the first movement in Beethoven's first sonata, Op. 12, there is an example of the second kind of transition just mentioned. It is from A major to F major. See another example about the middle of the *andante* in Haydn's Symphony, No. 4; transition from tonic G major to E flat major. Also another in the *adagio cantabile* of second quartett of Haydn's Op. 72; transition from E major to C major. All such powerful contrasts as those we have just spoken of, especially the transition from a given key to another a semitone above, ought to be very sparingly used. In dramatic music, and symphonies for an orchestra, these transitions may be very effective. The judicious composer may occasionally introduce them in music of a different description; for instance, in a cantata, or an instrumental quartett or quintett, &c. Excepting the cases we have mentioned of transitions made from one key to another without any intermediate chords, the general rule to be followed in modulating is to connect together the different keys by intermediate chords. In the proper selection of these intermediate chords consists the art of modulation taken in its widest sense. It depends entirely upon the relation or non-relation between the keys from and into which we modulate, what number of intermediate chords may be necessary to render the modulation smooth and agreeable. The manner in which these intermediate chords are to be disposed—direct or inverted, with or without dissonances or altered chromatic notes, &c.—rests with the composer's skill and imagination. One, or two, or

three, or four intermediate chords may be necessary, according to circumstances; but there is hardly any modulation that cannot be effected by means of four of these.

It is necessary to observe that, in many cases, the intermediate chords used in modulating from one key to another must have a sufficient duration given to them; otherwise the effect of the modulation will be harsh and displeasing.

No. 9.

From C major to D flat major. From C major to D major.

Both of these examples of modulation are harsh and unpleasant, because the intermediate chords are too few, and have not sufficient duration allowed to them; and yet they are given in a set of elaborate tables for modulation by Hudl, a German musician. Haydn never falls into errors of this kind. By taking care to prolong his intermediate chords sufficiently, he produces the smoothest and at the same time the most unexpected modulations. The following example, though not Haydn's, will illustrate this:

No. 10.

At A the modulation from B flat major into D flat major is gradually conducted. At B the same modulation is brought about too rapidly, and sounds harsh and unsatisfactory. Some good examples of Haydn's judgment in dwelling upon the intermediate chords when modulating, may be seen in the movement "Ecce mulier," in his "Seven last Words of the Passion." See the first nine measures of the second part of that movement, and from thirty-fourth to forty-fourth measures of same part.

A modulation frequently takes place into a key which is not a relative one to that immediately preceding, though both are related to the principal key of the piece. For example: 1. When the principal key is major, a modulation may occur from the second of the key to the third, from the third to the fourth, from the fourth to the fifth, from the second to the fifth. 2. When the principal key is minor, we may modulate from the fourth degree to the fifth, from the fifth degree to the sixth, from the sixth degree to the seventh, from the fourth degree to the seventh, and the converse of all these cases.

In modulating into a key not relative one (for instance, from G major into F major), care must be taken that the two keys are relatives to a principal key which has previously been sufficiently established; for it is only in such case that a modulation of that kind can be suitably employed. One may easily modulate from G major into F major by means of two intermediate chords in a piece of music of which the principal key is C major or A minor; but one could not do so if the principal key were D major or E minor; so that a modulation which is good in one case may become bad in another. This must always be kept in view with regard to modulations of the kind just mentioned. In order to modulate smoothly into a key more or less remote from the one we quit, we may employ two, three, or four modulations instead of one only. These may be called *compound modulations*. For example, to modulate from G major into F major, we may employ two modulations instead of one; the first, from G into A minor; the second, from A minor into F major.

As we can make a transition immediately from a major

Music. key to the minor key of its fifth below, so we can modulate into all the relative keys of the latter in setting out from the former; for example, into all the relative keys of F minor, beginning to modulate from C major. Again, we can modulate into all the relative keys of C minor, in setting out from C major. It is easier to modulate into keys that increase the number of their flats, than into keys that increase the number of their sharps. For instance, it is more difficult to modulate smoothly from C major into A major, than from C major into A flat major.

Sometimes, instead of using intermediate chords, a pause of some duration is employed between two keys that are not related to each other, and a modulation, or transition, effected in this way from the one key to the other. The longer the pause, the smoother the modulation in such cases. A single prolonged intermediate sound, not a *chord*, placed between two keys not relative, and followed by a pause, may also render the transition from the one to the other sufficiently smooth. For instance, after the chord

of G minor, introduce a prolonged E flat

and a pause, and then pass at once into the key of A flat major. Towards the end of the last movement of Beethoven's third Piano-forte Trio, Op. 1, there is a curious modulation from dominant of C minor into B minor by means of two prolonged sounds, G and F#. We may modulate from one key to another far remote, by means of a series of chromatic notes performed by one Part that seems to wander uncertain in quest of something. "Or su, or giù, ed or ricircolando." The finest example that we know of this kind of modulation is in the *Adagio Fantasia* of Haydn's sixth Quartett, Opera 76. The whole movement is charming.

As to what are called *enharmonic* modulations, or transitions, we shall pass them by, since they have no real existence upon keyed instruments. We refer to what we have said on this subject in the section on Harmony. We must remark, however, that they are dangerous delusions, and are continually giving rise to a number of harsh and intolerable pseudo-modulations in the music of young composers, and even in the music of experienced composers

Music. who ought to know better. No sooner has a young composer (not wisely taught) got acquainted with the *formulae* of these pseudo-enharmonic transitions, than he is eager to use them on all occasions, in order, as he thinks, to display his learning. He deceives himself, for his indulging in such things only betrays his ignorance of his art. "Modulation," said Piccini, "like all the other processes of the art, ought to be employed as a means of just expression and judicious variety. To modulate for the sake of modulating, is to prove one's ignorance of the object and principles of music. It is to affect a superabundance of imagination and of knowledge, in order to conceal the want of both."

We advise the student to examine carefully the works of the best composers, Italian and German, for examples of modulation, as well as of harmony and melody. There is no other way for him to acquire even a respectable knowledge of his art. As to the books published expressly upon modulation, some of them are written by Germans, and generally contain only mere *formulae* of the shortest ways in which modulations can be effected. These formulae the student ought to shun, except for mere reference; because, although the study of them might render him able to modulate in a dry and formal manner, they could never teach him that grace, and freedom, and effect, without which the most elaborate modulations are worthless.

Imitation is a musical artifice, by which a Part, called *Imitation*, the *antecedent*, proposes a subject, or melody; and another Part, called the *consequent*, repeats the same melody, after some rests, in any given interval, and so continuing to the end.

Example. Imitation in the Unison.

In an imitation the *consequent* is not always obliged to answer to the *antecedent* in the whole extent of the subject proposed by the latter. It may imitate only a part of the subject, and the *consequent* proposing a new melody, becomes, in its turn, the *antecedent*.

Imitation may take place in several ways. It is called *regular* or *constrained* when the nature of the intervals proposed by the *antecedent* is strictly observed in the response of the *consequent*. This of course happens when the *consequent* imitates the *antecedent* in the unison or the

octave. Imitation in the fourth or the fifth is the next nearest to exact correspondence of intervals.

Imitation is called *free* or *irregular* when this exact correspondence is not observed.

Imitation is by similar motion, by contrary motion, by similar retrograde motion, by contrary retrograde motion.

The other kinds of imitation are by *augmentation*, by *diminution*, by *countertime*; *interrupted*, *convertible*, *periodical*, *canonical*, &c.

Canonical imitation is that in which the consequent answers to the antecedent, note for note, from the beginning to the end. An imitation of this kind is what is called a

Music. canon, and may be treated in two ways. It may end with a *coda*, or complete close; or it may be made what is termed an *endless* or *circular* canon, when it is so constructed that we can return from the end of the imitation to the beginning as often as we please, without stopping. Music. Another kind of *circular canon* is one which modulates through all the twelve keys.

No. 4.

No. 5.

Endless Canon.

Kirnberger.

A canon written upon one stave, with particular signs to indicate how and when the different parts follow each other, is called a *close canon*. Latin enigmatical mottos were often applied to these close canons, to direct the performer mysteriously. Padre Martini has given a list of fifty-six of these mottos. When the canon is written fully out in score, or partition, it is called an *open canon*.

Double counterpoint.

The artifice of this kind of composition consists in combining the Parts in such a manner that they may, without inconvenience, be transposed from *acute* to *grave* if they are placed above the theme, and from *grave* to *acute* if they are placed below it, while the theme suffers no change in its melody, whether it exist in one of the extreme Parts, or in one of the intermediate.

These inversions may take place in seven ways, so that there are seven species of double counterpoint. In the *ninth* or *second*; in the *tenth* or *third*; in the *eleventh* or

fourth; in the *twelfth* or *fifth*; in the *thirteenth* or *sixth*; in the *fourteenth* or *seventh*; and in the *fifteenth* or *octave*. Those most commonly used are in the *tenth* or *third*; in the *twelfth* or *fifth*; and in the *fifteenth* or *octave*.

In double counterpoint the Parts ought to be, as much as possible, distinguished from each other by the different lengths of their notes. The Part which forms the counterpoint ought to begin after the theme. The Parts must not be allowed to cross one another without some cogent reason. In all double counterpoints, except that in the octave, it is not only permitted, but it is necessary, to alter intervals when inverting the Parts, especially when the modulations require this.

From what has already been said regarding the inversions of intervals, the following very short examples of double counterpoints will be more easily understood. But, for full explanations, we must refer to Marpurg and others; and, above all, to the works of the great masters.

No. 1. Double Counterpoint in the Octave.

Inversion of the same.

No. 2. Double Counterpoint in the Tenth.

Inversion of the same.

Inversion of the same.

Here occur some of the *alterations* of intervals lately mentioned.

No. 3. Double Counterpoint in the Twelfth.

Inversion of the same.

"Double counterpoint in the twelfth," says Cherubini, "is one of the most used, and one of the richest in resources." See his "Cours de Contrepoint et de Fugue," published in 1835. In this work he *specially* recommends Marpurg's *Treatise on Fugue and Counterpoint*, as the most

complete of any. We would advise the reader to consult Cherubini's work also, as containing admirable examples of his own composition. Reicha and Cherubini seem to be at variance as to the nature of Marpurg's work. Reicha says, "il ne parle, pour ainsi dire, que des imitations et des canons."

Music. In the symphonies, quartets, &c. of Haydn and Mozart, instances are frequent of the freest and boldest melodies being used in counterpoint with the best effect; but it is only the highest genius and most consummate skill that can do this.

There are also triple and quadruple counterpoints, susceptible of being inverted in various ways. Of these the best and most usual are in the octave, the tenth, or the twelfth.

Music.

No. 4. Triple Counterpoint in the Octave.

Quadruple Counterpoint in the Octave.

In these triple and quadruple counterpoints, where the subjects are merely doubled in thirds, there is a dryness and want of variety which had better be avoided by writing, in a free style, accessory accompaniments to the counterpoint. Our limits do not permit us to enter farther into this extensive subject. We refer to Marpurg, and Reicha, and Cherubini, for full explanations.

We must add the following passage from Cherubini: "All these examples give rise to an important remark, which is, that in spite of the denominations of *triple* and *quadruple* counterpoint, in the *tenth* or in the *twelfth*, there is no veritable *triple* or *quadruple* counterpoint, but that in the *octave*."

The fugue is a very complicated piece of music when it is carried to its highest pitch of artifice. It comprehends all sorts of imitations, canonical contrivances, and double counterpoints. Studied with proper views and within proper limits, so as not to interfere with the supremacy of melody and with the genius of a true composer, the fugue is extremely useful as an exercise of the student's ingenuity, and as tending to show him all the resources of artificial harmonic combination. To those who have learned to understand the artificial mechanism of fugues, and who can enjoy them on that ground, they are often very admirable things, though composers of great genius might have been better employed than in constructing them. Homer, Milton, or Shakspeare, would not have done justice to themselves, had they spent their time in writing difficult poetical puzzles, such as anagrams, acrostics, single, double, and triple poems in the shapes of crosses and triangles, or in which every word began with the same letter, as in the famous *Pugna Porcorum*, beginning "Plaudite porcelli porcorum pigra propago Progreditur," and so on for five closely printed pages. All such poetry is beyond the verge of the enchanted circle of poetical inspiration. So of all calculated artifices in music. If musical imitations, or canons of any sort, suggest themselves fluently and gracefully to a man acquainted with all the elements of the art, it is well; otherwise not; for mere dry labour ought to have no place in music. Since such artificial harmonic combinations can give pleasure to the initiated only, who have gone through a long training, there seems to be no reason why the laboured contrivances of imitation and fugue should have any preference over the simplicity of beautiful and expressive melody, and its adjunct, appropriate and effective harmony. We know well that this is all heterodox doctrine among a certain class of musicians, but do not the less adhere to our long-established opinion. With great respect for the knowledge and ingenuity of all eminent writers of canons or of fugues, we must remark, that all these artifices arose at a time when melody was in its infancy, and had not acquired, like Hercules, the power to

strangle the serpents that besieged its cradle. Among the greatest fugue writers are certainly to be reckoned G. P. Colonna, Handel, the Scarlattis, John Sebastian Bach, and his son Emanuel; and more recently Haydn, Mozart, A. Reicha, and Cherubini. Beethoven did not attempt much in this style, and what he attempted in it is not to be classed amongst his best productions. It is no wonder if a man of his towering genius and impetuous character was early disgusted by the arbitrary rules and restrictions imposed upon him by some of his unimaginative teachers, in such laboured music.

Cherubini says (we translate from the French), "The fugue, in spite of the ancient origin of the word, is, then, a creation of modern times, which was not practised in church-music until contrapuntists had freed themselves from the self-imposed obligation of working upon plain chant..... There are two kinds of fugue, from which a third kind emanates, and from this arise all the others. The two principal are, the *fugue of the key*, and the *real fugue*; the other is the *fugue of imitation*.¹ All the others, children of caprice, are *irregular fugues of imitation*, or *pieces in fugue style*. The indispensable conditions of the fugue are the *subject*, the *response* or *answer*, the *counter-subject*, and the *stretto*. To these conditions may be added the *pedal*, which is almost always employed in a fugue somewhat developed..... All the artifices which can be introduced into a fugue depend on the knowledge, the skill, and the choice of the composer, and at the same time on the nature of the *subject* and of the *counterpoint*, either or both of which may be more or less susceptible of yielding to these artifices. These artifices consist, in brief, 1. Of the employment of imitations, in detaching, to form them, a portion either of the *subject* or of the *counter-subject*; 2. in the transposition of the *subject* into different keys, and in the advantage which may be derived in this respect from double counterpoints; 3. in the inversion of the *subject* by contrary motion; 4. in a new *subject* which may be introduced, and which can be combined with the first *subject* and the first *counter-subject*; 5. in the manner of introducing the *stretto* in several ways, by drawing closer and closer, each time, the *answer* to the *subject*; 6. in the means that may be employed to make the *subject* and its inversion by contrary motion be heard simultaneously; 7. in the manner of combining the *subject*, the *counter-subject*, and the *stretto* upon the *pedal*; and in the address and the taste employed in enchainning together and introducing these artifices in the course of a fugue. All these combinations, and others besides, may be employed in a *studied fugue*; but, in a fugue for the public, a selection must be made from them, and they must not be all employed, otherwise the fugue would be too long and tiresome."

Reicha says, "it is essential to remark, that in our days the ancient fugue (or in the rigorous style) is no longer

¹ Reicha says, "Since fugues of the key are no longer composed, and as simple canons are not called fugues, the terms *fugue of the key*, *real fugue*, and *fugue of imitation*, are not really necessary, and only serve to confuse our treatises." (P. 56, 2d part.)

Music. composed quite under the same restrictions as in the time of Palestrina. At present we modulate in it a little more boldly, and employ more of dissonant chords. We sometimes introduce little chromatic phrases, and employ a greater variety in the values of the notes. We choose subjects of a more modern cast;—from time to time we permit successions of notes formerly prohibited, such as the diminished fourth, the augmented fifth, diminished seventh, minor seventh;—we add a coda;—we compose these fugues in all kinds of measures, &c.; so that we may say there exist three kinds of fugues: 1. The fugue entirely in the *ancient style*; 2. the *modern* or *free fugue*; 3. the *mixed fugue*, which participates in these two styles." (P. 4, part ii.)

Music. Cherubini remarks, that "although the denomination of *fugue with two, with three, and with four subjects* is generally adopted, this denomination is, in my opinion, improper. I think so, because a fugue cannot, and should not, have more than one single principal subject, to serve for its exposition. All that accompanies the subject is only accessory, and neither can nor should bear any other name than that of *counter-subject*. Thus, according to this principle, the fugue that we are accustomed to call *fugue with two subjects* ought to be called *fugue with one subject and one counter-subject*; that *with three subjects* should be called *fugue with one subject and two counter-subjects*; and, lastly, that *with four subjects* ought to bear the name of *fugue with one subject and three counter-subjects*," &c. &c. (P. 111.)

No. 1. Subject. Counter-subject.

Answer.

Octava Alta.

No. 2. Example of the *Stretto*, which consists in making the *Answer* follow the *Subject* as closely as possible.

Subject.

Answer.

Octava Alta.

No. 3. Example of the *Pedal*.

Octava Alta.

The *pedal* is a prolonged sound, sustained for several measures. It may be placed in the upper Part, or in a middle Part, and may occur on the key-note or the dominant; but in general it is best to place it in the lowest Part, and upon the dominant of the key.

For examples of vocal fugues, we refer the reader to Padre Martini's *Saggio di Contrappunto*; Paolucci's *Arte pratica di Contrappunto*; Choron's large work on composition, and his collection of musical classics. Clementi's collection, entitled *Practical Harmony*, contains a great variety of examples of instrumental fugues by different composers. Among the best of these are the fugues by Handel and the two Scarlattis, in the second volume. All

Handel's fugues are excellent studies, having more melody, force, and freedom, than most others of that period. Among what are called free fugues, we would point out two beautiful specimens in Mozart's overture to the *Magic Flute*, and in the last movement of his first violin quartett in G.

Cherubini gives an advice which the student will do well to follow. He says, "we will add here, that in all the kinds of counterpoint of which we are to treat, as well as in the fugue, the scholar ought to write for voices, and not for instruments. He ought to write conformably to the natural compass of the different kinds of voices. By this practice he will have the advantage of learning to

Music. produce effects by voices only,—a difficult study, and one perhaps too much neglected,—and he will find himself, afterwards, much more at his ease when he writes for instruments, and consequently is no longer obliged to confine himself within the limits of voices." Speaking of modulation (after having given general rules for it), Cherubini says, "Modern composers have freed themselves in their compositions from this simple and rational method of modulating, replacing it by a manner too free, and often incoherent; but if their deviations are tolerated in modern works, it is essential, and it is even expressly enjoined, not to follow these wanderings in the case of a composition so severe as the fugue."

Imitative music.

By imitative music we do not here mean the imitation of one melody or passage of melody by another, which has been already treated of in the section connected with canon and fugue; but the employment of music, more or less appropriately and successfully, to imitate certain natural phenomena, audible or visible. The great mystery of music lies in its power of suggesting and exciting ideas and feelings in persons endowed with a sufficient degree of sensibility and imagination. In this respect it resembles poetry, for poetry is a *dead* art to all who have not sensibility and imagination enough to receive and expand its suggestions. We speak of the higher poetry; not of that which attempts in vain to be minutely descriptive or imitative, and which, by so doing, loses the nobler essence of poetry, without attaining the object proposed.

There are many musical compositions that do not aim at imitation or expression of any determinate kind. Such are the great majority of pieces of instrumental music. Some fanciful persons have gone so far as to imagine a story told, or a scene described, by a quartett or a symphony, although the composer gave no indication of any such purpose, and would have transgressed the true imitative limits of his art by doing so.

One of these fanciful persons, Momigny, in his *Cours Complet d'Harmonie et de Composition*, has ventured to give what he calls "a picturesque and poetical analysis" of the introductory movement and succeeding allegro of Haydn's eighth Symphony in E \flat , and to add words here and there, to show what the music is intended to express. Momigny has also adapted words (see his third volume) to the first movement of Mozart's second Violin Quartett in D minor, and tells us that "he thinks he has discovered that the feelings expressed by the composer were those of a loving female on the point of being abandoned by the hero whom she adores," and that this luckless woman was Dido! All this, however, is mere imagination, and every one is at liberty to exercise his own fancy in such cases. In such a composition as Beethoven's famous Pastoral Symphony, it would certainly be impossible for any person to divine, merely from hearing it played, what was meant to be expressed or imitated by the different movements of that remarkable work. Unless he were previously told that such a movement was meant to express the sensations excited by visiting a country scene; such another, those felt beside a river; another movement meant to imitate a storm, and so on; certainly his imagination might lead him to guess very wide of Beethoven's intentions. The only things that he could have no doubt of, if accustomed to such rural sounds, would be the notes of the quail and the cuckoo, introduced in the river scene. As to the nightingale, he could make nothing of it, because the notes that Beethoven uses do not express the subtle song of that bird, any more than Handel's notes do in his song "Sweet Bird," in the *Penseroso*. In the oratorios and operas of eminent composers are to be found many instances of attempted imitations, most of which had better have been omitted. To attempt to imitate, by music, a hail or a

snow storm, the leaping or creeping of animals, the falling of walls, and so on, is to mistake the powers of the art. A particular style of music may sometimes be effectively employed to enforce the ideas conveyed by descriptive words. In Haydn's *Creation*, and *Seasons*, we have several instances of this. Among other passages, we may cite the song in the *Seasons* (pp. 396 to 408 of Leipsic Partition), describing the traveller wandering bewildered among the snow; and the chorus, "Oh! the tempest comes" (pp. 203, 230). In other parts of the *Seasons* we find passages intended to express the rustling of leaves, the running of a brook, the buzzing of flies, the crowing of a cock, the croaking of frogs, &c. but most of them unworthy of Haydn's genius. The overture to the *Seasons* is intended to describe the transition from winter to spring; the introduction to summer (p. 138), "the dawn of day;" the introduction to autumn (p. 252), "the husbandman's satisfaction in contemplating the abundant harvest;" the introduction to winter, "descriptive of thick fogs." All these are phenomena not susceptible of musical imitation; and the consequence is, that the fancy of the hearer might lead him to associate the pseudo-imitations with ideas totally different from those which Haydn intended to suggest. The philosopher D'Alembert says, "Si j'avois à exprimer musicalement le feu, qui dans la séparation des *éléments* prend sa place au plus haut lieu, pourquoi ne le pourrais-je pas jusqu'à un certain point par une suite de sons qui iroient en s'élevant avec rapidité?" and, a little after, "Si je voulois peindre le lever du soleil, pourquoi ne le pourrais-je pas par une musique dont le son auroit un progrès assez lent, mais iroit tout à la fois en s'élevant et en augmentant d'éclat, précisément comme le soleil quand il se leve?" Haydn, in the representation of chaos in his *Creation*, and in the introduction to the recitative "In splendour bright," in the same oratorio, seems to have had D'Alembert's ideas in view.

Many striking instances of indirect musical imitation may be found in the operas of Gluck. One of them occurs in his opera of *Iphigenia*, in the scene where Agamemnon deploras his daughter's lot in these words: "J'entends retentir dans mon sein le cri plaintif de la nature," &c. This "plaintive cry of nature" is expressed by the wailing notes of the oboe heard at intervals,

&c. while the "oracles of

destiny" are expressed by the gloomy and obstinate re-

sponses of the bassoon,

&c.

This remarkable passage is given, with a criticism upon it and some others from Gluck, in the first volume of Forkel's *Musikalisch-Kritische Bibliothek*.

The famous painter Leonardo da Vinci, in his Treatise *Musical on Painting* (c. xvi.), thus expresses himself regarding the invention aids to pictorial invention that may be derived from the contemplation of confused objects: "Se riguarderai in alcuni muri imbrattati, o pietre di varij mischj, potrai qui-vi vedere l'inventione e similitudine di diversi paesi, diverse battaglie, atti pronti di figure, strane arie di volti, et habiti, e infinite altre cose; perchè nelle cose confuse l'ingegno si desta a nuove inventioni." A painter of such genius as Leonardo da Vinci may have his imaginative faculties thrown into action by "a blotched wall, or by stones of various colours," or by other objects that would

Music.

produce no impression upon an ordinary man. So it is with the musical composer endowed with genius. To persons who feel and understand both poetry and music, poetry is well calculated to suggest musical ideas. We should think little of the musical genius of a man who could peruse the *Allegro*, or *Penseroso*, or *Comus* of Milton, and feel their beauties, without having his musical imagination strongly excited. To the musician of a poetical temperament (such as Beethoven), the glories of sunrise or sunset—the various gentler lights and shadows of morning or of evening—the more solemn and mysterious lights and shadows of the moonlight landscape—the wildness and vastness of mountainous scenery under all the aspects of “skyey influences”—the calm or the agitated sea—the dreary sounds of the tempest—the thrilling sublimity of the thunder-storm—will suggest musical ideas by some strange alchemy of mind yet unknown to musical theorists.

Musical invention, like poetical or pictorial, is really no more than the art of combining, in new and remarkable forms, certain elements presented to us by nature or by art. In music, vocal and instrumental, sounds are those elements; in poetry, sounds and language, signs that fluctuate in their nature and uses, and in their indications of innumerable external objects and endless shades of human feelings and passions; in painting, forms of infinite variety, and colours contrasted or combined in all the possible diversities of light and shadow. As to musical invention, or originality in melody and harmony, those who have the most extensive acquaintance with the musical compositions of the last two centuries must perceive that there is very little originality to be found in the compositions of our day. Melodic ideas and phrases, except of the most artificial kind, were nearly exhausted before the commencement of the nineteenth century. The works of Galuppi, Piccini, Sacchini, Paisiello, Sarti, and many other Italians, are now hardly known to the public; and yet from them the more modern melodists have drawn most of their best ideas of melody. The artificial combinations of harmony, and successions of modulations, had been carried to a great extent by some of the Italian composers—the Scarlattis and others—and by Handel and the Bachs and Bendas, and others among the Germans—before Haydn, Mozart, and Beethoven directed the public attention, not so much to a new style of melody and harmony, as to a *freer* style of both combined. They threw aside a number of fetters imposed upon composers by unreasonable rules drawn by theorists from anterior compositions of a conventional kind. Haydn, Mozart, and Beethoven—especially the two former—seem to have carried artificial music nearly as far as possible without rendering it void of pleasing melody, clear design, and intelligible harmony. Most other composers who have come after them, or who were their contemporaries, have done little more than caricature their styles. Some of the more fashionable composers who have deigned to keep any thing like melody in view, have had recourse to the older and forgotten masters, and pillaged them without mercy. But, after all, it must be confessed that no limits can be assigned to change and innovation in an art so vague and arbitrary in its general signification as music, and so dependent upon the training given to the public ear. That beauty and deformity are mere mental affections, and not existences separate from the sentient being who feels them and judges of them, is proved every day by the diversity of human opinions regarding productions of the fine arts. It is vain and absurd to argue upon these matters. The

Music.

old proverb that says “there is no disputing of tastes,” holds not only in things affecting the nerves of the tongue and palate, but also in things affecting the eye and the ear. It is not unworthy of remark, that the word “taste” has been so transferred from its original signification as to be applied, by common consent, to the senses of sight and hearing, and even to what may be supposed to be more intimately intellectual judgments regarding the merits of poetry and oratory. Where are we to find a perfect theory of poetry and oratory? although these arts stand at the head of all human arts. Choron writes as follows regarding musical invention: “In music, and in the arts in general, we call *idea* that which in a more exact language we call thought. However that may be, the musical *thought* or *idea* is usually a passage of melody which presents itself to the mind of the composer with all its suitable accessories. From this we perceive that there are many kinds of different ideas, according to the sort of effects, whether simple or compound, which they employ. We ought also to distinguish ideas into principal ideas and secondary ideas. The first are suited to form the basis or foundation of a composition; the others are applied to the development of the principal ideas. It requires art and experience to discern whether an idea belongs to the one or to the other of these classes; and also to perceive whether an idea is suited to the free or to the severe style of composition; and to be able to develop it according to the rules applicable to each of these styles. The art, or, more properly, the faculty of finding ideas, is called invention. This term sufficiently indicates that we look upon invention as almost entirely a gift of nature. No rules whatever can be laid down upon this subject. We can only offer some observations which may be useful. We distinguish two kinds of invention; invention properly so called, and invention by imitation. What we have just said applies particularly to the former kind; that kind of invention which creates new and original productions that do not resemble preceding ones, and that serve as models for succeeding productions. It is the most distinctive characteristic of genius. It is found in the details as well as in the general structure; in the manner as well as in the matter. An artist often shows as much genius in treating, in his own way, a common idea, as he could by producing new ideas. Invention by imitation consists in approximating, in peculiarities of style and manner, to some production already known.¹ Although this seems more easy than the other, it has its dangers and difficulties. The chief objection to it is the danger we incur of falling into plagiarism; a danger which cannot be avoided if we have not enough of imagination, taste, and skill, to enrich by accessories of our own, or to disguise dexterously, the materials which we endeavour to appropriate to ourselves. On the other hand, a happy imitation may be as good as a real invention. The talent of invention is developed by a continual application of mind to the object of invention, by the study of original works, and by directing the attention to seek in all things for the relations that they may have to the art which we cultivate. A thousand things that appear indifferent or useless to an inattentive man, become very significant to him who refers every thing to a principal object. We are often astonished that artists should have been so happy in their invention, and ascribe this to superior genius. We should be much more astonished if we knew to what circumstances they owe these advantages. The greater part of their talent consists in neglecting nothing, and in perceiving in what surrounds them every thing that can have connection with

¹ See Clementi's admirable preludes in imitation of the different styles of Haydn, Mozart, Dussek, &c.; and J. B. Cramer's parody of one of Dussek's Sonatas for the piano-forte; and Mozart's compositions in imitation of Handel's style.

Music. their art. If we are attentive in collecting every thing that presents itself, and take care to treasure up the ideas which occur in favourable moments, we shall soon form a rich collection of materials from which we can draw when occasion requires. Finally, we must never torture ourselves to find ideas; and must especially shun that mania of originality which induces us to reject easy and natural ideas, and to run after fantastical and perplexed ones. One may often present novelty under a guise almost common. On the contrary, as Boileau says,

Il est certains esprits dont la fougue insensée
Toujours loin du droit sens va chercher leur pensée,
Ils croiroient s'abaisser dans leurs vers monstrueux
S'ils pensoient ce qu'un autre a pu penser comme eux.

And all this is often mere lost labour; for an idea which at first seems new, on account of the manner in which it is presented, is frequently reduced to nothing when it is brought back to its true expression.

Develop- "If the gift of invention is invaluable, we may say that ment of musical ideas, and conduct of a composition. the art of conducting and developing ideas is not less important. We might cite many authors who, though not remarkable for variety or originality, have yet acquired a great reputation by the talent which they have shown in the development of their ideas. Among such authors are Sac-

chini and Anfossi; and in the works of authors very rich in invention might be pointed out pieces that have become highly celebrated, and of which the sole merit lies in the taste and the art shown in the development of the ideas." Most of Haydn's compositions are unrivalled models of skill and judgment in the development of musical ideas, and the conduct of the melody, harmony, and modulation. The study of double counterpoint, especially of that in the octave, is of essential importance to the attainment of skill in developing musical ideas. A knowledge of double counterpoint offers numerous resources to the composer of a symphony, an overture, an instrumental quartett, &c.; and, indeed, without such knowledge, it is impossible to make the most of one's musical ideas. This kind of knowledge is far remote from the dry and cumbersome learning of most of the older contrapuntists; learning which generally served no better purpose than to enable them with great labour to construct music *for the eye*, and not for *the ear*. To show the advantages that a composer of symphonies may derive from a knowledge of double counterpoint, we have only to refer to Haydn, Mozart, and Beethoven. Among Haydn's symphonies, the following movements occur to us at this moment as containing examples of what we have just been discussing. We refer the reader to the Partitions.

Sym. I. Allegro.

Sym. X. Allegro.

Sym. XVI. Allegro.

Sym. XVIII. Presto.

No writer on composition has treated so fully as Reicha of the uses of double counterpoint in the development of musical ideas. (See his *Traité de Haute Composition Musicale*, a large and expensive work, of 596 folio pages.) It is to be regretted that Reicha, in his two large works on composition, does not give examples from the works of the best composers. He does not even give direct references to such passages in the works of these composers as might illustrate his rules and observations. A man so versed as he was in music of all kinds could have done this easily; especially as his treatises were of great extent, and could have admitted of many classical examples, instead of those which he gives composed by himself or by his pupils. He says (p. 140 of first volume), "Now-a-days, it is required that the employment of any counterpoint should be effective. If a composer has not genius enough to accomplish this, he will do well not to make use of counterpoint. . . In all the treatises where counterpoint is spoken of, there is a defect, inasmuch as they neglect to show, in a satisfactory manner, the true resources offered by counterpoint. This is the cause that the public has never had a just idea of invertible harmony, and of its utility. Here is an example of a double counterpoint in the octave.

"This model of four measures gives eight in reckoning its inversion. This is nearly all that is generally known. But what is to be done with eight measures, it is asked, if there are no more? These eight measures may serve as follows.

"1. To form a canon for two unequal voices—(*i.e.* voices of different pitch and compass).

"2. To form an entire double fugue for two, three, or four Parts.

"And, which is more important in our days, these eight measures can be employed, *3dly*, in the course (chiefly in the second section) of a movement in a symphony, &c. where a very advantageous use of them may be made; as, for example, fragment of a movement in a

Music.

symphony for a grand orchestra, formed entirely from the preceding counterpoint."¹

Reicha then proceeds to show, by a Partition on the five following pages, the use and development of this counterpoint in the fragment above alluded to. We must refer to the passage in the original work.

Accompaniment.

This term sometimes signifies the harmonic support given to a melody or to a principal voice by one or more instruments, and sometimes means that knowledge of chords which is required in playing from a figured bass, or from a Partition. Since a voice or an instrument, or several voices or several instruments, may be accompanied by one or more instruments, the variety of combinations of this kind are almost endless. Melody, which forms the most expressive part of musical language, and regulates the march of composition by different rhythms, usually occupies either the highest or the lowest Part of a piece of music, in order to become more conspicuous. But sometimes, to produce a particular effect, the melody is placed in a middle Part. When this happens, or when it occupies the lowest Part, the accompaniment must be disposed accordingly, and constructed in such a manner as to produce the best possible effect in union with the melody. Since accompaniment is always subordinate to melody, some persons have looked upon it as an accessory of little importance, and have improperly compared it to the frame of a picture, or to the pedestal of a statue. This comparison, though having an appearance of justness, is really so absurd as to merit no refutation. Other persons consider accompaniment as a purely mechanical work, which requires only patience and application. If those persons mean by such work, the adding of some insignificant chords to a melody, they are not in the wrong; but such accompaniment is not that which we find in the works of Gluck, Piccini, Sacchini, Mozart, Winter, Cherubini, and other great composers.

Organ and piano-forte.

Two of the most important instruments used in accompaniment are the organ and the piano-forte. The organ is, in reality, a collection of wind-instruments of different kinds, forming in itself a species of orchestra, but not capable of the varied expression that can be given to a number of different wind-instruments played upon by different performers. Its noble and solemn effect renders it highly appropriate for the accompaniment of church-music; and it is much to be regretted that, in more modern times, its true character and powers have been too often lost sight of by injudicious composers and organists, who have introduced a style of performance and accompaniment quite unsuitable to the organ and to sacred music. The simple and *legato* style of accompaniment is that most suited to the nature and powers of the organ. In a memoir upon church-music (in the Italian language) by J. P. Schulthesius, there are many sensible observations upon this subject. The organ forms the best accompaniment to choral music, and in this case the organist ought to adhere to a simple and *legato* style. As an effective accompaniment to other sacred compositions, such as masses, &c., the organ is too much neglected by modern composers. The organ accompaniment ought always to be written in notes as the composer intends it to be per-

formed, and never left to be guessed at by the organist through the puzzling and uncertain signs of a mere figured bass. We refer to what we have said on the subject of thorough-bass in the section on harmony. When the organ is used along with an orchestra, as in Haydn's and Mozart's masses, and others, it would often be better for the effect, if the organ were more employed in strengthening the bass Parts than in giving the full harmony of the chords; because, in the latter case, the peculiar effects of some of the orchestra wind-instruments would be obscured or overpowered. Fine effects may be produced by a judicious use of only certain stops of the organ, even in accompanying with an orchestra. In some modern organs, the compass of the finger-keys (reckoned upwards from the eight-foot stop, or an open pipe eight feet long) is from the lowest C on the piano-forte up to F in alt, with all the intermediate semitones. In many other organs, the compass is not so extensive. There are, besides, stops of sixteen, and sometimes (in the largest organs) of thirty-two feet pipes, for the pedals. It must be observed, that in different organs the stops vary much in kind as well as in number, and that all the stops do not extend throughout the whole finger-keys, but in most organs serve for only one half of these keys. This is not the place to enter more minutely into the structure of the organ. Most foreign organs have pedals, or foot-keys, which generally extend to two octaves of the lowest sounds.

It does not appear to us that the extension, of late years, Piano-forte of the compass of the piano-forte, beyond its former compass of five or five and a half octaves, has been any real improvement of the instrument. The piano-forte is much used in accompanying music of various kinds, vocal or instrumental, or both. Songs, cantatas, vocal duetts, trios, quartets in chamber or concert-room music, instrumental solos, orchestral symphonies or overtures, operatic music, and so on, are all generally accompanied by a piano-forte. If the pianist understands his instrument thoroughly, has a knowledge of composition, and is well practised in reading from Partitions, he may give important assistance to the performers whom he accompanies, even when there is a complete orchestral accompaniment besides. He may do this more especially where singers are accompanied by an orchestra. Supposing that a pianist has to accompany a piece of vocal music of the old Italian school, and with nothing but the voice Part or Parts and a figured bass before him; he must not only be a good harmonist, but also well acquainted with the peculiar style of harmony and accompaniment suitable to such compositions, and really intended by the author, although not expressed by the imperfect system of thorough-bass notation anciently employed. Among these ancient composers, who were almost all excellent harmonists, there was a method of accompaniment practised by them as appropriate, and which, from tradition and habit, was clearly understood even by means of the imperfect and conventional signs of thorough bass. But this is no longer the case; and a modern pianist who would accompany a cantata of Alessandro Scarlatti, or a duett of Clari, or a psalm of Marcello, and so on, as the composer intended, must make a particular study of the older style of accompaniment, otherwise he will fail in his attempt to accompany such compositions.

Music.

¹ "This fragment being placed in the second section of the movement, supposes that the first or the second subject of the counterpoint, or both, have been previously heard in the first section. Without this precaution, the hearer would feel it as something foreign to the movement, as out of place, which would be a fault on the composer's part. To render this counterpoint appropriate

to the movement, it is enough that the four measures

form a part of the

subject of the movement."

Music. He will make the harmony too full, or too thin, or dispose it in an unsuitable manner. As we have not room for examples of the style of accompaniment suitable to such music, we refer the reader to the edition of Marcello's Psalms, published in Paris some years ago by Mirecki, a pupil of Cherubini. It was revised by Cherubini himself. In that work the accompaniments are given as they ought to be, and may serve as models for the accompaniment of such music, and of much of the music of that period—the latter part of the seventeenth and the earlier part of the eighteenth centuries. The accompaniment of the compositions of that period for voices is generally attempted by modern pianists in mere dry chords read from the thorough bass figures and notes. Such an accompaniment is quite erroneous in so far as regards the composer's intention, because the accompaniment of these pieces was an *accompagnamento figurato* for three Parts, each of which Parts had its own melodic progression, and the whole three were so contrived as to sustain the voice or voices, and enforce the effect of these without overpowering them.

To accompany a Partition from which the pianist has to select, on the instant, those parts most important to the effect, while he leaves out others, or portions of others, requires great practice and knowledge, especially with regard to more modern Partitions. Formerly, the most important parts of a Partition were the two violins, viola, and violoncello, forming a quartett that represented the essential structure of the composition. The wind instruments were at that time employed much more sparingly and less effectively than they afterwards were in more modern music. There are other circumstances in the structure of the older Partitions which render it less difficult to accompany them than the more modern ones. But, with regard to the pianist's accompaniment of Partitions, especially modern ones, we may remark, that the attempt too often made by injudicious accompaniers to crowd into the piano-forte accompaniment all the orchestral effects that they see in a Partition, is worse than useless. The thing is impossible, from the nature and powers of the piano-forte, and its uniformity of *timbre*. We have already alluded to this in the section on Harmony. Where there is any particular and prominent design in the Parts of a Partition, the pianist ought to adhere to it in his accompaniment, in so far as the nature of such design and the powers of his instrument will permit. In many cases he must be content to sacrifice much of the design, and of the grace and freedom of movement, found in the Parts of the Partition, and to arrange his accompaniment in such a way as to make the most of the difficulties presented to him by the construction of the Parts. This will frequently occur to him in accompanying modern Partitions, which often contain so elaborate a construction of Parts as almost to defy any attempt to represent even a shadow of them in the piano-forte accompaniment. The best way of learning how such intricate Partitions may be suitably accompanied by the piano-forte, or how they may be arranged for the piano-forte, so as to accompany the voice Parts (for example) without any other instrument, is to study carefully the best Italian and German arrangements of the best Italian and German operas, oratorios, masses, &c. for the piano-forte, with the voice Parts; for example, Clementi's admirable arrangement of Haydn's *Creation*; the best French or German editions of the similarly arranged masses and operas of Mozart, Winter, Cherubini, Beethoven, &c. To render this study really useful, the accompanier must, at the same time, have before him, and consider attentively, the Partitions from which these arrangements were made. No abstract rules can teach the art of accompaniment. Nothing but talent, experience, and observation can do so; and therefore we would urge the student to go at once to the interesting fountain-head of good models, and not to waste

time upon dry technicalities. Many pianists make a very easy matter of accompaniment, by reducing it to a series of dry chords (*accords plaqués*) or else broken chords in the vulgar form of what some musicians used to term "chopped hay." For the proper piano-forte accompaniment of modern songs, duets, &c. the reader may consult the compositions of this kind by Haydn, Mozart, Cherubini, Beethoven, Himmel, &c. where the accompaniments are written by the composers themselves. The harp, although introduced of late years into orchestras, is not very effective in such a situation, unless when occasionally left nearly alone to accompany some vocal Part in an opera, or in concert-room music. It serves better for an accompaniment in chamber-music. The guitar, skilfully managed, forms a pleasing accompaniment to a single voice in songs of a certain character. Although the greater part of its sounds belong to the bass and tenor range, music for the guitar is written in the treble clef; so that the sounds heard are really each an octave lower than they are represented by the notation.

Before we conclude this section, we must advert to a fault not uncommon in the compositions of Germans for voices with orchestral accompaniments. Even Mozart himself has sometimes committed this fault. It occurs when the harmony for two or three voices is incomplete, and a succession of fourths, for example, is left to have the harmony completed by some of the instruments of the orchestra. This filling up of the harmony by the instruments does not produce the desired effect; for the imperfect harmony of the voices,—from their peculiar and prominent *timbre*,—is still perceived. The best modern Italian composers are more careful in this respect. They make the harmony of their voice Parts complete in itself, and independent of completion from the orchestral accompaniment.

The comparative simplicity of orchestral combinations in the works of the older composers has been adverted to in the preceding section. Gluck, in the latter part of the eighteenth century, was one of the first composers who introduced wind instruments into the orchestra in a manner more effective than had till then been practised. Any musician who will take the trouble to examine Gluck's Partitions will perceive that they suggested to other composers many ideas of orchestral effect from the use of wind instruments,—ideas more fully developed by Haydn, Mozart, Cherubini, Mehul, Beethoven, and others. The invention of new instruments, the improvement of old ones, the introduction into orchestras of instruments formerly confined to military music, have produced a superabundance of materials for orchestral effect; a superabundance sadly abused by many modern composers. The consequence of such abuse has been too frequently nothing better than a chaotic confusion, arising from the simultaneous combination of so many heterogeneous instruments. The *elaborate noise* of a modern orchestra is sometimes so great as to stun all ears but those petrified by custom. Men who serve artillery get so accustomed to the din and roar of cannon that they suffer no more annoyance from such noise than other untrained persons do from the distant explosion of a spent rocket in its highest altitude. They come at last to relish the martial din that deafens a common bystander.

In the section upon voices and instruments, we have occasionally adverted to the most suitable employment of some of the latter in orchestral music. We shall here offer a few more remarks upon this subject, and upon orchestral music in general.

A complete orchestra consists of a number of stringed instruments and wind instruments, and a few instruments of percussion; the latter being generally kettle-drums. The nature and magnitude of an orchestra must be regu-

Music.**Orchestral music.**

Music.

lated by the locality, since a large orchestra in a small theatre or concert-room, or the converse, would be ineffective, though from different causes. The relative proportion of the instruments in an orchestra is of much importance to its effect. The orchestra of the Italian opera at Vienna is small, in order to suit the locality. It was recently as follows: one conductor, one violin *obbligato* for accompanying particular parts of the vocal music, one leader and five first violins, six second violins, four viole, four violoncellos, four double basses, two flutes, two oboes, two clarinets, two French horns, two bassoons, two trumpets, three trombones, one drum, one double drum, one piano-forte; in all forty-three instruments. This is about the same number and proportion as in the orchestras of Dresden, Francfort, and the Italian opera at Paris. The orchestra of the opera at Berlin is much larger, on account of the greater size of the house. In those smaller orchestras, the wind instruments are suited in size and tone to the fewness of the stringed instruments. The double basses, too, are small sized, and have four strings, except the principal one, which has five, to facilitate the execution of difficult passages. The orchestra of the grand opera at Paris lately consisted of twenty first violins, twenty second violins, fourteen viole, thirteen violoncellos, six three-stringed double basses, three four-stringed double basses, four harps, four flutes, four oboes, four clarinets, four bassoons, three trombones, horns, trumpets, kettle-drums, one serpent. The number of performers in the orchestras of the Scala at Milan, and San Carlo at Naples, used to be, at most, about ninety-three; but their number varies, and has of late been reduced.

Trumpets, trombones, the serpent, and kettle-drums, are too noisy to be suited to a small orchestra; and the judicious composer will, in such a case, avoid them. In writing for an orchestra, the stringed instruments form, as it were, the body of the composition, or a complete harmony in four Parts among themselves. This quartett consists of first and second violin, viola, and violoncello; the double basses being employed to enforce the violoncello Part. The number of violins, viole, and violoncellos, makes no difference in the real harmony of this quartett, because if there are twenty first violins they all play the same Part, and so of the second violins, and viole and violoncellos respectively. But, for the sake of variety, the full quartett is not always continued through a whole movement, but is sometimes interrupted by harmony in two or three Parts, and by passages in unisons or octaves. Occasionally, also, but more rarely, the stringed instruments cease altogether for a short period, to allow a passage for wind instruments alone to be heard with more effect from contrast; for instance, in the trio of Beethoven's first symphony in D major, Op. 36; in the trio of his symphony in C major, Op. 21; and in the trio of his *Sinfonia Eroica*, Op. 55; and, *passim*, in the orchestral compositions of Haydn, Mozart, Cherubini, Weber, Spohr, &c. The stringed instruments of the orchestra are often employed without being accompanied by any of the wind instruments. By the addition of wind instruments of different kinds, and in different ways, to the stringed instruments, a great variety of combinations and effects take place, which open a wide field of resources to the composer. It is important to remark, that whether the stringed instruments form a quartett, a trio, or a duett, their harmony ought to be good in itself, independently of the addition of any wind instruments. The same remark applies to the harmony of a duett, trio, or quartett, formed by a combination of wind instruments. The harmony must be good and pure, independently of any filling up by the addition of stringed instruments. It is hardly necessary to say, that the uses which may be made of all these possible combinations of the wind instruments with the

stringed ones, or of wind instruments with wind instruments, depend entirely for their good effect upon the skill and judgment of the composer. One of the wind instruments added to the stringed ones, may either double one of the parts of these, if its nature permit it to do so, or may have a distinctive melody given to it, and be accompanied by all, or by only one, or two, or three of these parts; and thus, in the latter case, form with them a quintett, or quartett, or a trio, or a duett for the time being. Thus, the bassoon or the horn, for example, may double the bass part of the stringed instrument quartett of the orchestra, or any of the other parts, to produce a particular effect of reinforcement; or it may have a distinctive melody, and be accompanied as before mentioned. The same remark extends to the flute, the oboe, the clarinet; with this exception, that instruments of a high pitch, like these, are not properly employed to double the bass parts of the orchestra. By this *doubling* of a part is to be understood the addition to it of another instrumental part, which performs the same melody in unison, or in octave higher or lower, according to the nature and compass of the added instrument. When accompanying a wind instrument of a great pitch with two violins, the accompaniment is generally above the melody. In this case, the melody should form a good bass to the accompanying harmony; and if it does not, then the orchestral basses must be employed to supply the defect. To accompany a bass instrument which has a principal melody, with other instruments of a higher pitch, often requires much dexterity in the management of the harmony.

The number of possible combinations of the different instruments in an orchestra is so great, that we cannot here enter into the subject. To study the art of orchestral combinations with most pleasure and most advantage, one must have recourse to the partitions of the best German and Italian composers of operatic and orchestral music, from Gluck and Piccini downwards to Haydn, Mozart, Cherubini, Beethoven, Spohr, Rossini, Weber, &c. In studying the partitions of some of the latest composers, one should guard against being led away by the love of noise and the affectation of singularity too often found in them.

If what we have had space for upon a subject so extensive should be of use to the professional student, or to the amateur, our object—the advancement of music in our native country—will be so far attained. We conclude by requesting the musical student to keep in view that there is no royal road to a true knowledge of his art; and also that in music, as well as in other things, Condillac's observation holds true:—"Les règles sont comme des garde-fous mis sur les ponts, non pas pour faire marcher les voyageurs, mais pour les empêcher de tomber."

The limits prescribed to this article necessitated the greatest possible condensation in every section of the subject. Therefore the reader is referred, for additional information, to the introduction and the appendix to this treatise, published in a separate form, under the title of *Essay on the Theory and Practice of Musical Composition*. It is necessary to observe, that of late years various wind instruments mentioned in the article MUSIC have received great improvements, and that some new ones have been invented. By giving additional finger-keys, &c., to flutes, oboes, and clarinets, passages that were formerly very difficult or impracticable on these instruments, are now rendered comparatively easy. Among the brass wind-instruments similar improvements have been introduced, and the semitonic scales within their compass completed. Sax, of Brussels, and his son have become celebrated for the excellence of their wind-instruments, both of wood and of brass, some of the latter being new inventions. In England, France, and Germany, also, wind-instruments have been much improved. Besides, several new wood and brass instruments have been introduced into orchestras and military bands, such as the bass clarinet, the Saxophone, &c.

(G. F. G.)

Music.

Musk
||
Musonius.

MUSK, a peculiar secretion found in the preputial gland of a small animal of the natural order Ruminantia. The musk animal (*Moschus moschiferus*, Linnæus) is found in Asia, and is often called the *musk deer*, but it cannot properly be classed under the genus Deer. (For information respecting it, see MAMMALIA.) The gland, or *pod*, as it is technically called, from which the musk is obtained, varies from one inch and a half to an inch and three-quarters in width, and often exceeds two inches in length. When first removed, it contains the secretion in a soft, almost liquid state; but it hardens by careful drying, and when removed is not unlike dark-coloured snuff, coarsely granulated. A good musk-pod contains about two drachms and a half of musk, the great value of which (L.3 to L.3, 10s. per ounce) leads to a variety of ingenious adulterations, in which dried blood and grain tin are much used. The Chinese even imitate the pods, and tins, too, with so much success, that it is difficult to detect the fraud, except by very nice and experienced examination. It is imported in *catty-boxes*, usually containing from twenty to twenty-five pods. Musk is employed in perfumery and medicine; and, considering the powerful nature of this perfume, and the only source from which it can be obtained, the quantity used is very considerable. In 1856 the import was rather more than 5000 ounces, and as each pod weighs nearly an ounce when dry, this would necessitate the destruction of 5000 animals for the supply of England alone, where musk is not a favourite perfume, except in combination with other materials.

One of the most remarkable qualities of musk is the extraordinary persistence of its perfume. Specimens have been examined one hundred years old, the scent of which has been as powerful as recent musk; and the nicest balance has failed to detect any loss of weight in musk which has been so placed as to perfume a whole room for upwards of thirty years. In medicine, musk is occasionally used as an antispasmodic. It is also slightly narcotic, but it is not often administered. The duty on musk was reduced in 1832, and repealed entirely in 1845. (T. C. A.)

MUSLIN, a fine kind of cotton cloth, with a downy nap on its surface. The name is said to be derived from Mosul in Asia, where it was originally manufactured. It was first imported into England from India in 1670, and is now manufactured in immense quantities both in Britain and on the Continent, rivalling in quality, and surpassing in cheapness, the finest products of the eastern looms. (See COTTON, and COTTON MANUFACTURE.)

MUSONIUS, CAIUS RUFUS, a Stoic philosopher, was the son of a Roman knight, and was born at Volsinii (*Bolsena*) in Etruria about the beginning of the first century. He early became a disciple of the doctrines of the Porch. But his maxims, as quoted by Stobæus, A. Gellius, and others, have a more direct reference to practical than to speculative ethics. Since the ills of life are essentially paltry, he held that they ought to be met by quiet resignation, not avoided by suicide. The cultivation of the virtues of austerity, disinterestedness, chastity, and temperance, is the sure and the only means of securing happiness. "Everywhere," said he, "one can be happy, for everywhere one can be virtuous." The happiness of man is thus lodged within himself. It is not therefore necessary that we should defend ourselves from the injuries of others by inflicting retribution in return. The best way to make our fellows respect us is to respect ourselves. Such an elevated tone of morality was not palatable to the depraved court of Nero. Musonius accordingly fell into disgrace. Under the pretext of having been privy to the famous conspiracy of Piso against the emperor, he was banished to the isle of Gyarus (*Ghioura*) A.D. 66. He appears to have returned on the accession of Galba in 68; and he is found shortly afterwards among the deputies who were sent by the Emperor Vitellius to Antonius Primus, the victorious general of

Vespasian. Yet he subsequently rose high in the favour of Vespasian, so that he was allowed to remain in the city when all the other Stoics were driven into banishment for their intolerant precepts. The date of his death is unknown. The extant fragments of his works have been collected and published by Peerlkamp, under the title of *C. Musonii Rufi Reliquiæ et Apophthegmata*, 8vo, Haarlem, 1822.

MUSSCHENBROEK, PETER VAN, an eminent natural philosopher, was born at Leyden in March 1692. Studying at the university of his native city, he became a proficient in classics under Perizonius and Gronovius, and in natural philosophy, chemistry, and medicine, under Sen-guerd, Bidloo, Le Clerc, Burman, Albinus, Boerhaave, and Rau. The teacher, however, from whom he derived the most profit was the eminent mathematician Gravesande. A scientific partnership was formed in 1717 between the master and the pupil, for the prosecution of natural philosophy according to the principles of Newton, and in opposition to those of Descartes. Gravesande concentrated his attention on the theoretical part of the study; Musschenbroek conducted the experiments; and both, by their separate investigations, corrected or confirmed the results obtained by each other. The consequence was, that the downfall of Cartesianism, and the establishment of Newtonianism, were very much accelerated in Holland. In increasing the knowledge, and in determining the future studies of Musschenbroek, the effect was also great. An inaugural dissertation which he delivered in 1718, on the occasion of taking his degree, brought out into full prominence his taste and talent for experimental science. It was entitled *De Aeris Præsentia in Humoribus Animalium*, and was full of experiments, carefully prosecuted and clearly explained. His fame was now established. He was appointed professor of natural philosophy and mathematics, and professor extraordinary of medicine in the university of Duisburg in 1719. In 1723 he was promoted to the chair of natural philosophy and mathematics at Utrecht. He was now placed in his proper sphere, and began to prosecute his favourite studies with increased vigour. His first important production was *Epitome Elementorum Physico-Mathematicorum*, 12mo, Leyden, 1726,—a work which was afterwards gradually altered as it passed through several editions, and which appeared at length in 1762, under the new title of *Introductio ad Philosophiam Naturalem*. The publication in 1729 of his next great work, *Physica Experimentales et Geometricæ Dissertationes*, raised his reputation to its acme. It threw new light on the subjects of the magnet, capillary attraction, and the cohesion of bodies. Scarcely less instrumental in advancing science was his Latin edition, in 1731, of the Italian work *Saggi di Naturali Esperienze fatte nell' Accademia del Cimento*. The numerous notes which he appended to this translation contained, amid many other curious investigations, a description of a new instrument, the pyrometer, which he had invented, and of several experiments which he had made on the expansion of bodies by heat. His great eminence was acknowledged in this same year by an invitation from the King of Denmark to Copenhagen. He declined this honour, and was promoted in consequence to the chair of astronomy at Utrecht in 1732. The attempt of George II. of England in 1737 to attract him to the newly-established university of Göttingen was also unsuccessful. At length, however, the claims of his native city overcame his resolution to remain at Utrecht, and he took possession of the mathematical chair at Leyden in 1739. Here he resolved permanently to settle. Offers of preferment from Berlin, Madrid, and St Petersburg, were tendered to him in quick succession; yet, declining all these honours, he continued peacefully to instruct his pupils, and to pursue his favourite investigations till the day of his death in September 1761.

Musschenbroek is also the author of *Elementa Physicæ*

Musschen-
broek.

Mussel-
burgh
||
Musset.

8vo, 1734, translated into English by Colson, in 2 vols. 8vo, 1744. He contributed a dissertation on Barometers to the *Memoirs of the Academy of St Petersburg*, and several papers on Meteorology to the *Memoirs of the French Academy of Sciences*, and to the *Transactions of the Royal Society of London*.

MUSSELBURGH, a royal burgh of Scotland, county of Mid-Lothian, at the mouth of the Esk, 6 miles E. of Edinburgh. The town proper stands on the right bank of the river; and on the other side is the village of Fisherrow, with which it communicates by three bridges, one of which is believed to be of Roman architecture. The principal street of Musselburgh extends E. and W., and is nearly straight; the houses being in general well, though not regularly, built. The parish church stands on a hill to the S. of the town; and there are also Free, United Presbyterian, Episcopal, and Independent churches. In the principal street is a town-hall, with a jail attached, the latter having been built in 1590, out of the remains of the ancient chapel of Loretto, which existed in the vicinity. The town contains several schools, two libraries, and a savings-bank. Some Roman antiquities have on different occasions been discovered at Inveresk, where it is supposed that a Roman colony was once settled, and where traces of ancient baths have been discovered. The links, which stretch along the shore of the Firth of Forth, are extensive, and on them the Edinburgh races are annually held. They are also much used for the game of golf. The manufactures are few and unimportant, being chiefly leather, sail-cloth, and fishing-nets. The inhabitants of Fisherrow are, as the name of the place implies, chiefly employed in fishing; and this village, along with Newhaven, supplies the inhabitants of Edinburgh with fish. The harbour of Fisherrow is small, dry at low water, and is only visited by a few vessels of small size. Musselburgh is connected with Edinburgh, by a branch of the North British Railway; and large quantities of coal are conveyed from the pits in the vicinity to Edinburgh and Leith. The town is historically important on account of the battle of Pinkie, which was fought in the neighbourhood in 1547, when the Scottish army was defeated by the English under the Earl of Somerset. Oliver Cromwell also encamped here in 1650; and part of his entrenchments remain near the church. Musselburgh forms one of the Leith burghs which join in electing one member of Parliament. Pop. (1851) 7092.

MUSSET, LOUIS CHARLES ALFRED DE, a distinguished poet, novelist, and dramatic writer of the nineteenth century in France, was born at Paris on the 11th November 1810. He was of noble descent; his father, M. de Musset-Pathay, held the office of *chef du bureau* to the minister of war, and was favourably known as an author. His *Histoire de la Vie et des Ouvrages de J. J. Rousseau* is still held in estimation. Alfred received his education at the same institution with the eldest Prince of the House of Orleans, and the intimacy formed at this early period between the prince and the poet was fondly cherished in after years. The loss sustained by De Musset in the early death of his noble friend, was afterwards consecrated in *Le Treize Juillet*. After completing his elementary education, Alfred de Musset engaged successively in the study of medicine, of law, of art, and of trade; but turned aside from each with equal disgust. He subsequently laid the blame of his want of success in those studies on his superficial education, his indolence, and desultory habits of reading. His first appearance as an author was in 1828, in a pamphlet entitled *L'Anglais Mangeur d'Opium*, and signed with his initials. He published in 1831 his *Contes d'Espagne et d'Italie*, a series of licentious tales in verse, exhibiting vast powers and wild extravagance, possessing singular merits in point of form, and abounding with impassioned and vigorous writing. *Un Spectacle dans un Fauteuil* appeared in

1833, and possessed all the merits, and many of the defects, of his previous poems. They display a power and beauty seldom to be met with, and are never wanting in that subtle wit and delicate observation which so remarkably distinguish his prose works; but they are justly chargeable with extravagance, indecency, and irreligion. His charming *Proverbs*, which appeared in the *Revue des Deux Mondes* in 1833, are much less exposed to censure, and are full of poetical beauties of the highest order. Ten years afterwards they were brought upon the stage at St Petersburg, by Madame Allan, whence their fame travelled back to Paris, and soon called forth the enthusiasm of the Théâtre-Française. In 1835 De Musset visited Italy in company with Madame Dudevant (George Sand), in the ostensible relation of private secretary. In fullness of tone, wealth of colouring, and rich sustained melody, the language and style of these two distinguished contemporaries resemble each other not a little. *La Confession d'un Enfant du Siècle* appeared in 1836, and is alleged by some to be in a great measure autobiographical. The theme is familiar to all readers of modern French fiction; and finds its origin in the conventional view of the mental history of Byron, whose writings have exerted a profound influence over the current literature of France. Musset was poor, and his habits of dissipation did not increase his wealth. When his purse was full, he lived in Paris till it was empty, and then retired to the country. He declined to occupy the distinguished place in society which his genius and manners might have secured for him. By the influence of his early friend the Duc d'Orleans, he was appointed librarian to the minister of the interior. He was deprived of this sinecure office in 1848, but it was subsequently restored to him by the emperor. His *Nouvelles*, originally published in the *Revue des Deux Mondes*, are among the most remarkable of modern tales. These charming stories, so slight and unpretending in their structure, are masterpieces of a fine and subtle genius; and it is only to be regretted that their beauty is so much marred by the dangerous sensualism with which they are pervaded. The beautiful tale of *Frédéric et Bernerette* contains the most delightful portrait of the French grisette ever drawn, and is a special favourite with the Parisians. Musset's earlier collection of *Premières Poésies* comprise the period between 1829-1835; his second *Poésies Nouvelles* embrace the period 1836-1852. At the beginning of this second collection stands *Rolla*, marking the turning-point between the youth and manhood of the author. It is the wildest of all his productions, and in many respects the most remarkable; but the English reader is shocked by its impiety, and his feelings are outraged by the feverish delineations of certain modes of life which are fortunately not known beyond the French capital. Despite all these serious drawbacks, however, the genius of Alfred de Musset possesses qualities seldom hitherto known in French poetry. He occasionally reaches heights of imagination unknown perhaps to the greatest writers of his country; and his lyrics display a passion, tenderness, and musical beauty almost alien to his native soil. Those who consider the life of an author the best commentary on the tendency of his works, will find little difficulty in denouncing Musset's as pernicious; while those who regard works of art from a purely artistic point of view, will find much in his writings to call forth the highest praise. He was not a voluminous writer. A few small volumes contain all his works. His *Nouvelles* occupy less space than an ordinary romance, his poems may be read in a few hours, and his plays are by no means bulky. He died at Paris on the 3d of May 1857.

MUSSOUREE, in Hindustan, a sanatory station on the northern frontier of the Dehra Dhoon, established by the British to relieve and remove the consequences prejudicial to health from the sultry climate of India. There is no

Mussulman level area of any extent at this station; so that the houses are built at considerable distances from each other, on sites which it has been necessary to level, on a ridge, a crag, or on the southern slope of the mountain. The views are very beautiful, comprising on the N. the Himalaya Mountains, clad in perennial snow; and on the S. the rich and varied expanse of the Dehra Dhoon, beyond which the prospect extends over the vast plain of Hindustan. In the latter part of winter there are smart frosts, with occasional falls of snow; neither, however, occurring after March, when spring sets in. Then succeeds delightful weather, which continues till the middle of June, when the periodical rains commence. Mussouree is abundantly supplied with provisions. It has a church, which was erected in 1837. The little settlement is well managed, and flourishing. Of the diseases contracted in the plains, the effects of a residence here are found favourable to fevers, dyspepsia, dysentery, liver complaint, pulmonary consumption, rheumatism, and general debility. Elevation above the sea, 6282 feet; N. Lat. 30. 27., E. Long. 78. 5.

MUSSULMAN, or **MOSLEM**, the general name given to all who profess the faith of Mohammed. (See **MOHAMMEDANISM**.)

MUSTAPHA, the name of several Turkish sultans. Mustapha I. succeeded his brother Achmed I. in 1617, was deposed a few months afterwards, was restored to the throne in 1622, was again deposed in 1623, and was strangled in 1639. Mustapha II. succeeded his uncle Achmed II. in 1695, was deposed in 1703, and died in 1704. Mustapha III. succeeded his cousin Othman III. in 1757, and died in 1774. Mustapha IV. succeeded Selim III. in 1807, was deposed in 1808, and was murdered by his brother Mahmud in 1809. (See **TURKEY**.)

MUSTARD, the English name of a genus of cruciferous plants, of which several species yield useful seed. The best known and most used is *Sinapis nigra* (Linn.), an indigenous plant, which is extensively cultivated for its seed in some parts of England, particularly in Northumberland and Yorkshire. Large mills are employed for grinding the seed, and for converting it into flour of mustard, the condiment so universally used at our tables. Table-mustard is, however, a compound, as it would not, in the opinion of some, be agreeable in an unmixed state. (See Christison's *Dispensatory*.) The materials added are varied by different manufacturers according to taste. It appears, however, from the published evidence taken before the select committee on the adulteration of food in 1856, that the adulteration of mustard is so extensive, that as a medical appliance it is generally ineffective. (Dr Challice's evid., *Blue Book*, p. 94.) In consequence of the extreme difficulty of obtaining pure mustard, a manufactory of that article has recently been established by government in Her Majesty's victualling-yard at Deptford, so that the Royal Navy is now supplied with mustard perfectly pure. The chief adulterations are flour, turmeric, and gypsum. Turmeric is used to improve the colour of the mustard, and especially to increase the profit of the manufacturer. Its presence may easily be detected by the use of ammonia. (Gay's evidence, *Blue Book*, p. 103-5.) Mustard was not known at our tables in its present form till 1720, when a Mrs Clements of Durham fell upon the present mode of preparing it. Her mustard met with the approval of George I., and soon became highly popular. Mustard is also of considerable importance in the materia medica. *Sinapis alba* (Linn.) is also cultivated for this purpose, but not to a very great extent. It is the sort which is commonly grown with cress in our gardens as a salad herb. The genus has a very wide geographical range, some species being indigenous in Europe and others in India. In the East Indies *Sinapis nigra*, *S. glauca*, and *S. Toria*, are very extensively cultivated for the purpose of expressing oil from the seeds, very large quantities of which are ex-

ported to this country for the same objects under the names of *rape* and *surzee* seeds. The total imports of these seeds from India in 1856 was 21,417 quarters, all consumed in the manufacture of oil. Some of the oil so made is used for burning, but the greater portion is employed in dressing woollen goods. (T. C. A.)

MUTINA. (See **MODENA**.)

MUTINY. (See **MILITARY LAW**.)

MUTIUS, CAIUS, surnamed *Codrus*, and afterwards *Scævola*, was one of the illustrious Roman family of the Mutii, and rendered his name famous in the war between Porsenna, King of Tuscany, and the Romans. That prince having resolved to restore the family of Tarquin the Proud, went to besiege Rome in the year 507 B.C.; but Mutius determined to sacrifice himself for the safety of his country, and boldly entering the enemy's camp, killed Porsenna's secretary, whom he took for Porsenna himself. Being seized and brought before Porsenna, he told the king boldly that three hundred young men like himself had sworn to murder him; "but since this hand has missed thee," continued he, "it must be punished;" then putting his right hand on the burning coals, he let it burn with such constancy as astonished the beholders. The king, amazed at the intrepidity of the young Roman, ordered that he should have his freedom and return to Rome, and soon afterwards concluded a peace with the Romans. From this action Mutius obtained the surname of *Scævola*, or left-handed, which was enjoyed by his family.

MUTIUS SCÆVOLA, Q., surnamed the *Augur*, was an excellent civilian, and instructed Cicero in the laws. He was made prætor in Asia, and afterwards became consul, when he performed important services for the republic. He must not be confounded with Quintus Mutius Scævola, another excellent civilian, who was prætor in Asia, tribune of the people, and at length consul 95 B.C. He governed Asia with such prudence and equity, that his example was proposed to the governors who were sent into the provinces. Cicero says of him, that he was the most eloquent orator of all the civilians, and the most able civilian of all the orators. He was assassinated in the temple of Vesta during the wars of Marius and Sylla B.C. 82.

MUTTRA, in Hindustan, a British district under the jurisdiction of the lieutenant-governor of the north-west provinces. It lies between Lat. 27. 14. and 27. 58., Long. 77. 20. and 78. 34.; and includes an area of 1607 square miles, with a population of 862,909. Muttra, the capital of the district, is described by Bishop Heber as a striking town, much resembling Benares, its houses being lofty, with the same sort of ornaments as in that city. The place is regarded as sacred in Hindu mythology, from being the birthplace of the divinity Krishna. Towards the close of the last century the town of Muttra was seized by Scindia, the Mahratta chief, who conferred it on the French adventurer Perron, on condition of military service. In October 1803 it was, without resistance, occupied by the British troops, and in the same year permanently ceded to the East India Company by Scindia, under the treaty of Serjee Arjengaum. Muttra is in N. Lat. 27. 30., and E. Long. 77. 45.

MUZIANO, GIROLAMO, an eminent Italian painter, was born at Acquafredda, near Brescia, in 1528. Under Romanino, an imitator of Titian, he studied his art, and became an adept in designing and colouring according to the principles of the Venetian school. But it was not until he had left his native place, and had repaired to Rome about 1550, that he came into notice. There his pictures soon gained for him the surname of *Il Giovane de' Paesi* ("the young man of the landscapes"). Stimulated by success, he tried the more elevated style of historical painting. He imitated Michael Angelo in giving great prominence to the anatomy of his figures, and became fond of painting persons emaciated by abstinence or disease. His great picture of the

Mutina

Muziano.

Mycenæ
||
Mycenæ.

"Resurrection of Lazarus" at once established his fame as an historical painter. Michael Angelo praised it, and pronounced its author one of the first artists of that age. It was placed in the church of Santa Maria Maggiore, but was afterwards transferred to the Quirinal Palace. Muziano, with dogged perseverance, continued to proceed in the path on which he had so successfully entered. He grew excellent in depicting foreign and military dresses, and in introducing landscapes into his historical pieces after the manner of Titian. Mosaic working also occupied his attention; and from being a crude art of inlaying coloured stones, it became under his hands a perfect imitation of painting. His ability and industry soon gained for him a handsome fortune. Part of this he expended in assisting to found the Academy of St Luke at Rome. He died in 1590, or, according to another authority, in 1592, and was buried in the church of Santa Maria Maggiore, where his great masterpiece was placed.

Many of Muziano's works are in the churches and palaces of Rome. There is his group of "Anchorites listening to a Saint," in the church of the Carthusians; his "Circumcision," in the church of Gesù; his "Ascension," in the church of Ara Coeli; and his "St Francis receiving the Stigmata," in the church of the Conception. A picture by him, representing Christ washing the feet of his disciples, is in the cathedral of Rheims. (Lanzi's *Storia Pittorica*.)

MYCENÆ or MYCENE, an ancient city of Greece, stood about $7\frac{1}{2}$ miles N.E. from Argos, on a rocky height in a recess of the mountains that border the Argeian plain. Its name is said to have been derived from Mycene, daughter of Inachus, or from the Greek word *μύκης*. It was founded by Perseus; and, according to a favourite legend, its massive walls were reared by the strong hands of the Cyclopes. After the death of Perseus it was ruled in succession by Sthenelus and Eurystheus; then coming into the power of the Pelopidae, it gradually rose into importance until, under the sway of Agamemnon, it became the first city of Greece. But no sooner had that powerful prince died, than Argos began to assume a supremacy over the other towns of the plain. The Mycenæans were soon fain to trust to their strong walls, and to an alliance with Sparta for protection against their aggressive neighbours. At length, in 468 B.C., the Argives, summoning to their aid the inhabitants of Tegea and Cleonæ, sat down before Mycenæ. After a blockade, the city was forced to capitulate, and was ever afterwards abandoned to desolation. In the second century A.D., its ruins were visited by Pausanias. They are still very extensive, and are the most ancient in Greece, next to those of Tiryns. The walls of the Acropolis exist, in a greater or less degree of preservation, round almost the entire circuit. They consist in some places of huge misshapen blocks piled up irregularly, and in other places of stones, skilfully hewn and regularly placed. At their N.W. angle is a gate, formed of three long massive stones, surmounted by two enormous lions in bas-relief, and called on that account the Gate of Lions. On the S.W. of the Acropolis the site of the lower town is indicated by the remains of a wall extending from N. to S. In this part of the ruins there are four subterraneous erections in which, according to Pausanias, the treasures of the Atridae were deposited. One of these, called the Treasury of Atreus, consists of two apartments, the outer of which is large, and the inner comparatively small. (Leake's *Morea*, and Mure's *Tour in Greece*.)

MYCONE, or MICON, a small island in the Ægean Sea, situated in N. Lat. 37. 29., E. Long. 25. 21. It is of a triangular form, and in length is $8\frac{1}{2}$ miles from E. to W.; in breadth from N. to S., 6 miles. The surface is rugged, but does not rise to a very great height, and the soil is dry but fertile. Wine and fruit are the principal products of the island, and it also contains abundance of game. There is very little water here, and the wants of the inhabitants

are for the most part supplied by rain water. The town of Mycone stands on the N.W. coast, and is chiefly inhabited by sailors, who are reckoned among the best in these seas. The roadstead is exposed to all winds except those from the N.N.E. Pop. of the town about 5000; of the island, about 6000.

MYHERE, in Hindustan, a petty native state in the territory of Saugor and Nerbudda, containing an area of 1026 square miles, and a population of 100,000. The present chief is a minor, and arrangements have been made for his education at Agra, under the direction of the British government. Myhere, the principal town, is in N. Lat. 24. 16., E. Long. 80. 49.

MYLÆ (*Milazzo*), an ancient town of Sicily, was situated about 30 miles W. from Cape Pelorus, on the isthmus of a peninsula of 5 miles in length. It assisted, according to Strabo, in 648 B.C., in colonizing Himera. It was for many centuries a dependency of the Greek colony of Messana. Laches took it in 427 B.C.; and the Rhegians, in 394 B.C., attempted to make it the seat of an opposition to Messana. It enjoyed separate municipal privileges in the time of Pliny; and its importance as a military station is still great.

MYLASSA, or MYLASA (*Melasso*), a noble city of Caria in Asia Minor, situated about three leagues from the *Sinus Ceramicus*, in a beautiful plain at the foot of a steep mountain, containing fine white marble, of which its buildings were composed. It was the capital of Hecatomnus, King of Caria and father of Mausolus, and the birthplace and residence of the Carian kings before Halicarnassus became the capital. The chief citizens of Mylassa were made priests of Zeus for life; and the splendour of its temples was the wonder of all who visited it. Caria was taken by Mithridates, and afterwards by Labienus, whose father had been one of Cæsar's generals. Hybrias, whose eloquence and valour entitled him to a distinguished rank amongst his countrymen, in vain encouraged them to make an obstinate defence. He himself was obliged to yield to necessity, and to take refuge at Rhodes; but scarcely had the conqueror quitted the city, when Hybrias returned and restored liberty to his country. Pliny calls it *Mylasa libera*; and Strabo informs us that it was one of the most magnificent cities of antiquity, and that its temples, porticoes, and other public monuments were highly admired. When Pococke visited this place it was comparatively perfect, but at present few traces of it remain. (See Leake's *Asia Minor*, and Fellows' *Journal and Discoveries*.)

MYLNE, ROBERT, the architect of Blackfriars Bridge, London, was the descendant of a family of architects, and was born in Edinburgh in 1734. Having adopted at an early age his hereditary profession, he was sent to the Continent to complete his studies. His enthusiastic prosecution of his art soon brought him into notice. He became a most distinguished pupil, and ultimately a member of the Academy of St Luke at Rome. Returning to England, he executed a design for Blackfriars Bridge, which was chosen from among twenty others. The bridge was begun in 1760, was finished in 1769, and established the fame of its architect. He was employed to erect or improve many edifices throughout the kingdom. The office of engineer to the New River Water-works Company, and the surveyorship of St Paul's Cathedral, were conferred upon him. While holding this latter appointment he suggested the famous inscription to the memory of Wren in St Paul's, "Si monumentum quæras, circumspice." He died in 1821.

MYMUNSING, a district of Hindustan, in the province of Bengal, situated between the 24th and 26th degrees of north latitude. The boundaries of this territory are the Garrow Mountains and the district of Goalpara on the N., Dacca Jelalpoor on the S., Silhet on the E., and Bogra and Rungpoor on the W. The country is intersected by the

Myhere,
|
Mymun-
sing

Mynpooree great river Brahmapootra, into which flow innumerable streams from both sides; and which overflows its banks during the rainy seasons, causing very abundant crops of rice. Some parts of the country are overrun with jungle, and are but thinly inhabited. The chief town is Bygonbary. The population is 1,487,000, consisting of nearly equal numbers of Hindus and Mohammedans.

MYNPOOREE, in Hindustan, one of the north-western provinces of Bengal. On the N. it is bounded by the province of Budaon, on the N.W. and W. by Furruckabad, on the S. by Etawah and Agra, and on the W. by Muttra and Allyghur. It lies between Lat. 26.54. and 27.50., Long. 78.30. and 79.30.; and contains an area of 2000 square miles. The population amounted in 1853 to 832,714; of whom 619,659

are Hindu, agricultural; 161,422 Hindu non-agricultural; Myriapoda. 20,093 Mohammedans and others, agricultural; and 31,540 of those various classes, non-agricultural. The tract of which this province forms part was included in the Mohammedan empire of the Afghans, overthrown by Baber. On the dismemberment of the empire of Delhi it became part of the transient realm of Nujuf Khan, in virtue of a treaty of partition between him and Shuja-ood-Dowlah, the vizier of Oude. After the death of the former it was seized by the Mahrattas, and in 1803 was ceded to the East India Company by Dowlat Rao Scindia, under the second article of the treaty of Serjee Anjengaum. Mynpooree, the principal town of the province, contains a pop. of 21,000. N. Lat. 27. 14., E. Long. 79. 4.

MYRIAPODA,

A WINGLESS tribe of insects, formerly so called, of which *centipedes* (the genus *SCOLOPENDRA* of Linnæus) form the most characteristic example, are now regarded as a separate class of the articulated tribes, in conformity with the views of Dr Leach and other writers who have studied their structure and economy. Under this title, therefore, as formerly intimated,¹ we shall present the reader with a brief notice of the principal genera, of which the prevailing forms have been already exhibited (in connection with our representations of insects) on Plate CCLII. of this work. We owe the establishment of the class to Dr Leach,² M. Lamarck having viewed the Myriapoda as arachnides,³ while M. Latreille, except in a single work,⁴ regarded them as true insects. As such they were likewise included by Linnæus, and the older systematic writers, in the order APTEA.

The Myriapoda are distinguished from true insects by their greater amount of feet (twenty-four and upwards), by the want of any precise or appreciable division into thorax and abdomen, and by the numerous segments into which their bodies are divided. Each segment, with the exception of the first, is furnished with a pair of legs, terminated for the most part by a single hook. The stigmata, or openings for respiration, are placed on each alternate segment, a circumstance which has induced some observers to regard the latter as only semi-segments, in as far as in true insects each ring has its pair of stigmata. But we see no necessity for the establishment of any strict analogy of form between the subjects of two distinct classes of articulated beings; and indeed, if we do so in regard to the character in question, we produce a greater discordance by the necessity, in that case, of assigning to each so-called (double) segment, a couple of pair of legs. The mandibles are bi-articulate, and are followed by a piece in the form of a labium, quadrifid, with articulated divisions resembling little feet, and corresponding in position to the *languette* of the Crustacea. Then succeed two pair of small feet, of which the second, sometimes hook-shaped, seem to replace the four maxillæ of the last-named order, or the two maxillæ and the lower lip of insects. They may be regarded as maxillary feet. The antennæ are two in number. Their form cannot be easily generalised, because, although they may often be, as Latreille says, "courtes, un peu plus grosses vers le bout, ou presque filiformes;" yet in some (genus *Scutigera*) they are very long, and become much more slender towards the extremity. The number of the articulations also varies greatly. The organs of vision are usually formed by a union of smooth or simple eyes; but

in some these parts are analogous to the compound eyes of insects, the facettes, however, being proportionally larger, rounder, and more distinct. All Myriapodes are apterous.

The subjects of our present notice differ likewise from insects in this remarkable peculiarity, that the number of their segments, and consequently of the stigmata and legs, increases with the size of the individual. It would even appear, from the observations of Savi the younger,⁵ that the genus *Iulus* is born without feet; from which it has been observed, that those Myriapodes are subject, at some early period of their lives, to a regular metamorphosis. Degeer had long before observed, that the number of their parts increased with the general growth of the body.

The organs of respiration consist of two principal tracheæ extending parallel along the body, and receiving air from the lateral spiracles.

Myriapodes are generally supposed to be longer lived, and of more continuous growth, than insects; and, according to Savi the younger, two years elapse (at least in the genus *Iulus*) before the development of the generative system; but it must be borne in mind, that many insects exist for a length of time in the larva state (to which the early condition of the Myriapodes so closely corresponds), and are thus of equal longevity with the many-footed subjects of our present inquiry. The Myriapodes in general shun the light. They conceal themselves under stones, beneath the bark of trees, among old timber, and in various other localities. Some inhabit fruits, and others are destructive to culinary vegetables. Many are carnivorous, seizing upon animal substances, both dead and living, with their curved jaws. They are said to infuse a poisonous juice into their wounded victims.

In our subdivision of the class, as in the preceding generalities, we shall follow the system of Latreille, by whom the Myriapodes are partitioned into two primary groups, which differ from each other both in habits and structure.

ORDER I.—CHILOGNATHA.

This primary group corresponds to the genus *Iulus* of Linnæus. The body is for the most part cylindrical, and of a crustaceous consistence. The antennæ are composed of seven joints, of nearly equal size. The mandibles are thick, without palpi, distinctly divided into two portions by a median articulation, and with teeth implanted in a concavity of their upper extremity. Beneath is a kind of labium or lower lip, divided at its exterior surface, by

Myriapoda.

notches and longitudinal sections, into four principal areas, tuberculated on the upper margin, and of which the two intermediate are short and narrow, and placed at the upper extremity of another area, which serves them as a common base. The feet are very short, and always terminate in a single hook; four anterior feet placed immediately beneath the labium, resemble the others in form, but are more approximate at their base, with the radical joint proportionally longer. Most of the other legs are attached by double pairs to a single segment of the body. The male organs are placed beneath the seventh pair of legs, those of the female behind the second pair. The stigmata, as usually described, are very small, and placed on alternate segments outside the origin of the legs.

The Myriapodes of this division are slow of movement, and advance, as it were, by a gliding motion. They assume in defence a round or spiral form. The first segment of the body, in some the second, is larger than the others, and presents the form of a corselet or buckler. The double pairs of legs do not occur until we reach the fourth, fifth, or sixth pair; the first three or four pair being free from their origin, or adhering to their respective segments only by a median or sternal line. The two or three terminal segments of the body are usually without feet. On each side of the body there is a series of pores, formerly regarded as stigmata, but which, according to M. Savi, merely emit an acid liquor of a disagreeable odour, and probably intended as a means of defence; the true stigmata, or respiratory openings, as described by the Italian naturalist, being placed on the sternal piece of each segment, and communicating internally with a double series of pneumatic pouches, disposed *en chapelet* along the body, and giving out tracheal branches, which ramify over the other organs. These pouches or vesicular tracheæ, according to M. Straus, are not connected with each other, as among ordinary insects, by a principal trachea.

The form of the newly-hatched bodies of the Iulidæ, as observed by M. Savi in the vicinity of Pisa, was somewhat kidney-shaped, quite plain, and without appendages. After the lapse of eighteen days they underwent their first moult, and only then assumed the form of the adults; but they were still composed of only twenty-two segments, and the total number of their legs amounted to twenty-six pair. These observations are in some measure inconsistent with the assertion of Degeer, who in the young state of these creatures counted only three pair of legs and eight segments: but is it certain, asks M. Latreille, that the moult described by M. Savi was actually the first; or ought we not rather to presume that they do not pass suddenly from an apodal state to the possession of twenty-six pair of legs; in other words, that they are subject to certain intermediate changes, which may have escaped the observation of M. Savi?¹ After the second moult, however, the last-named naturalist informs us, the genus *Iulus* exhibits thirty-six pair of legs, and after the third, forty-three, and the body then consists of thirty segments. In the adult state the number is considerably increased. Two years afterwards another moult takes place, and it is only then that the generative system is developed. From the period of birth, which takes place in March, the renewals of the skin were observed by M. Savi to take place almost monthly till November, and the exuviae were seen to contain even the membrane which lines the interior of the alimentary canal and tracheæ. The organs of the mouth were the only parts not there observed by M. Savi.²

The food of these Myriapodes consists both of animal and vegetable substances, generally dead and decomposed. They deposit a great number of eggs. The generic groups are as follows. We shall enter into few details, as we have illustrated so many of the prevailing forms by means of accurate figures.

GENUS GLOMERIS, Lat. Body convex above, concave below, with a range of small scales along the lower sides. It is composed of twelve segments, exclusive of the head. The male has thirty-two legs, the female thirty-four.

The species are not numerous. Although *G. ovatus* inhabits the sea, the greater proportion are terrestrial, occurring under stones, particularly in mountainous countries. *G. marginata* (Plate CCLII., fig. 1) is common in most European countries.

GENUS IULUS, Lat. Body cylindrical and extended, without any projecting crests or cutting margins.

The larger species are terrestrial, and live in woods; the smaller attack fruits, roots, and various kitchen produce, to some of which they are very destructive. They all assume a spiral position in repose or when alarmed; the head being placed in the centre. Prior to the time of Latreille, this entire division was included under the genus *Iulus*, Linn. But the French naturalist restricted the term to the cylindrical species, and formed of the others his genera *Glomeris*, *Polydesmus*, *Polyxenus*. Various species are described by Dr Leach, in a paper which stands in need of revision.³ We have here figured *I. sabulosus*, a common European species, Plate CCLII., fig. 3. A monstrous Myriapod is mentioned by Ulloa as inhabiting the district of Carthage.⁴ He describes it (if his terms have not been mistranslated) as sometimes extending a yard in length, and measuring five inches across. Here there is no doubt some gross exaggeration. He adds that its bite is mortal, if a timely remedy be not applied. From its cylindrical form it has been regarded as an *Iulus*.⁵

GENUS POLYDESMUS, Lat. Body linear, the segments compressed on the under surface, with projecting ridges on the upper, somewhat in the form of transverse oblong scales.

The species of this genus, of which our *Iulus complanatus*, Linn., may be regarded as the type (Plate CCLII., fig. 2), dwell under stones in dampish places. They assume the spiral form when touched, and feed both on animal and vegetable matters in a state of decomposition.

Certain other species, of which the eyes are obvious, form the genus CRASPEDOSOMA of Dr Leach.

GENUS POLYXENUS, Lat. Body soft, membranous, terminated by a tuft of lengthened scales.

The only species of which we have any knowledge is the *Pol. lagurus*, Lat. (Plate CCLII., fig. 5), regarded as a scolopendra by the generality of systematic authors, and described by Degeer under the name of *Iule à queue en pinceau*.⁶ It is a very small creature, of rather singular aspect. Our magnified representation just referred to will save the necessity of descriptive details. Its early organization is less complicated than that of the adult state; that is, the young consist of fewer segments and a less number of legs. We know little of its natural habits. It occurs in the clefts of walls, and beneath the bark of old trees.

ORDER II.—CHILOPODA. Lat.

This division of the Myriapoda bears nearly the same relation to the unrestricted genus *Scolopendra* of Linnæus,

Myriapoda.

as the preceding does to the genus *Iulus* of the Swedish naturalist. The antennæ become slender towards the extremity, and are composed of fourteen articulations and upwards. The mouth is composed of two mandibles, each furnished with a small palpi-form appendage, and exhibiting in their centre the appearance of a joining, and ending in a spoon-shaped termination, with toothed edges. The labium is quadrifid, with the two lateral divisions larger than the others, transversely ringed, and resembling the membranous feet of caterpillars. This labium is analogous to the lower lip of the chilognathous kinds, which represents in Latreille's opinion the tongue of the crustaceous tribes, but possesses also the functions of maxillæ. It is what Savigny names the first auxiliary lip. Besides these parts, there are two palpi or minute feet, united at the base, and unguiculated at the point; a second labium (*seconde levre auxiliaire* of Savigny¹), formed by a second pair of feet dilated and joined at their origin, and terminated by a strong hook, moveable, and pierced at the extremity, for the transmission of a venomous or acrid liquid.

The body of these unseemly creatures is depressed and membranous. Each ring or segment is covered by a coriaceous plate, and usually bears only a single pair of legs; and the terminal segment is generally thrown backwards, and elongated into a kind of tail. The organs of respiration are composed, either in whole or in part, of tubular tracheæ. The sexual parts are interior, and placed at the posterior extremity of the body, as in the generality of insects properly so called. The stigmata are more obvious than in the preceding family, and are either lateral or dorsal.

The species of this division are of much more nimble habits than those of the preceding; and the peculiar mode in which the limbs act produces an undulating lateral motion. They are of carnivorous habits, and, avoiding strong light, usually conceal themselves under stones or old timber, beneath the bark of trees, &c. They are held in some dread by the inhabitants of tropical countries, where they attain a great size, and are consequently capable of inflicting dangerous wounds. But the majority of travellers seem agreed that, although the bite is more painful than that of a scorpion, it is never attended by fatal consequences. In more northern countries they are quite harmless, though disliked in consequence of their repulsive aspect. Our common centipede (*Scolopendra forficata* of Linn.) so frequent in this country under stones, may be mentioned as a familiar example. Leeuwenhoek, the great Dutch microscopical observer, has described the perforation of the hooks, through which the poison is supposed to flow.

This order (which corresponds to the SYNGNATHA of Latreille's earlier works, the title adhered to by Dr Leach) is divided into the following genera.

The first two have only fifteen pair of legs; and their bodies, when viewed from above, seem to present fewer segments than when examined from below.

GENUS SCUTIGERA, Lamarck.² Body covered by eight plates or shields, beneath each of which are two pneumatic pouches or vesicular tracheæ, which receive the air, and communicate with lateral and inferior tracheæ of a tubular form. The under surface is divided into fifteen

semi-segments, each bearing a pair of feet terminated by an extremely long, slender, and minutely articulated tarsus. The terminal legs are long, and seem to increase in extent from the foremost to the hindmost pair. The eyes are comparatively large and reticulated. The antennæ are very long and slender, and the palpi projecting and spinous.

The species keep themselves concealed during the day in barns, or the unfrequented parts of houses, lying between old planks, or sometimes under stones. They are seen at night running on the outside walls with great velocity, feeding on *onisci*, and various insects. They seem to pierce their prey with their mouth-hooks, and infuse into them a poisonous fluid, which immediately deprives them of life. These Myriapodes make their appearance in great numbers, chiefly in rainy weather. According to Illiger, they are greatly dreaded by the inhabitants of Hungary. The best known European species is the *S. araneoides* (Plate CCLII., fig. 4). It is the *Scolopendra coleoptrata* of Linn. and Fab. Pallas asserts that it was taken by a friend of his among some fuci in the sea;³ but as all analogy is against its natural occurrence in such a locality, we may infer that it had fallen accidentally from the timbers of a vessel.

GENUS LITHOBIUS, Leach. Body divided into an equal number of segments both above and below, each bearing a pair of legs. The dorsal plates are alternately long and short. The stigmatic openings are lateral.

We have figured our most common species, *L. forficata* (Plate CCLII., fig. 6), a familiarly-known Linnæan scolopendra, as an example of the modern genus. It occurs almost everywhere, throughout the summer season, under stones. The anatomical structure of the genus has been described by M. Leon Dufour.⁴

The remaining generic groups of this order have at least twenty-one pair of legs, and the segments of the body are of nearly equal size, and of similar number, both above and below.

In the genus SCOLOPENDRA, properly so called, there are eight distinct eyes, four on each side, and the basal joint of the terminal legs is armed with small spines. We have no British species, but the south of Europe produces *Scol. cingulata*, which presents almost as formidable an aspect as some of the exotic kinds. The great foreign species (one of which sometimes measures above a foot in length) have been as yet ill defined, several kinds being no doubt described under the name of *Scol. morsitans*, a native of South America (Plate CCLII., fig. 9). A monstrous species, called *Scol. Plumieri*, is figured in Lister's Journey to Paris, and appears to be also represented in Seba's Thesaurus, under the name of *Millepeda major ex Nova Hispana*. India, and the great eastern islands, produce some very large species; and scolopendræ of alarming size likewise occur on the African continent. The bite of these creatures is said to be dangerous;⁵ but it seems that the poison of the wound is allayed by the use of ammonia. M. Amoreux is of opinion that no poisonous power is possessed by any of the European species.⁶ The whole are carnivorous and voracious, and, all things considered, they may be regarded as among the ugliest of creeping things. Nevertheless they are not without their advantage to the human race. "I have seen Indian chil-

¹ This piece is not attached to the head, but to the anterior extremity of the first semi-segment. The two hooked feet form by the union and dilatation of their first article a plate in the form of a labium or mentum, and the same semi-segment bears the two first ordinary feet. (*Règne Animal*, iv. 336.)

² Latreille and others have adopted Lamarck's designation, although the title of *Cermatia* had at a prior period been assigned to this generic group by Illiger. See Rossi's *Fauna Etrusca*, t. ii. p. 299.

Myrobalans
||
Myron.

dren," says Humboldt, "of the tribe of the Chuymas, draw out from the earth and eat millepedes or scolopendræ, 18 inches long and 7 lines broad."¹

Other species, in which the eyes are obliterated or inconspicuous, and the basal joint of the last pair of legs is free from spines, form the genus *CRYPTOPS* of Dr Leach.² He has described two English species, and nobody appears to have since found any other elsewhere.

Some still more slender kinds, of which the antennæ have

only 14 joints, but the legs are so numerous as sometimes to amount to nearly 300, compose the genus *GEOPHILUS* of Dr Leach. They are remarkable for their extreme tenuity, and at least one British species is at times beautifully phosphoric. We know not, however, whether it is identical with the *Scol. electrica* figured by Frisch, and described by Geoffroy.³ Dr Leach has described the indigenous species.⁴ They are destructive to fruit and vegetables. (J. W.)

Myrrh.

MYROBALANS are the unripe drupe-like fruits of a tree found in the East Indies, growing from 40 to 50 feet in height. It is the *Terminalia Chebula*, Roxburgh, of the natural order Combretaceæ. (See BOTANY.) The myrobalan of commerce is about an inch and a-half in length, oval in shape, dry, hard, and wrinkled, and of a brownish-yellow colour. It was first imported in 1842 as a substitute for galls in dyeing black, and was for some time supposed to be a gall, and returned as such in the revenue accounts. The quantity imported during the first three years only amounted to about 8 tons; but so greatly has the demand increased in consequence of the valuable properties of the myrobalan, that in 1856 the importation had reached 3150 tons. The myrobalan is gathered unripe, and then dried in the sun, and packed into pockets containing about half a cwt., and bags holding about one and a half cwt. Of these bags, the number imported in 1856 was 41,250, and of the pockets 2300, nearly all of which are brought from Bombay. The value is, according to quality, from 6s. to 12s. per cwt. With the salts of iron the myrobalan yields nearly as fine a black as the Turkish oak-gall; and from the fact that it contains a large quantity of tannic acid it has been extensively used in tanning when more than ordinarily cheap. Besides black, they yield various shades of yellow and yellowish-green, with proper mordants. There are numerous species of myrobalan, some of which are very useful. They are,—the *Terminalia citrina*, Rox., used as a gentle aperient in Indian pharmacy; the *Terminalia belerica*, Rox., the seeds of which are eaten, and are likewise used in tanning and dyeing; the *Terminalia catappa*, Linn., yielding the edible kernels called Indian almonds; the *Terminalia glabrata*, Forsk., eaten in the Society and Friendly Islands; the *Terminalia angustifolia*, Jacquin, formerly celebrated for its richly odorous gum; and the *Terminalia alata*, used in tanning operations in India. The emblic myrobalan, the fruit of *Phyllanthus emblicus*, Linn., is used for similar purposes in the East Indies. (T.C.A.)

MYRON, one of the most famous of Greek statuary, was born at Eleutheræ in Bœotia about 480 B.C. He studied along with Polyclethus under Ageladas of Argos, and flourished at Athens about the commencement of the Peloponnesian war. Some of his works were executed in marble, but he wrought most successfully in the bronze of Delos. The range of his subjects was not confined to the varied attitudes of the human figure. It also comprised the forms of other animals; and this fact distinguished him from the rest of the great statuary of Greece. Another characteristic of Myron was the want of all idealization in his works. "He was," says Pliny, "curious in all corporeal detail, but paid little regard to expression." There was an air of ease in his statues which indicated the admirable spontaneity of his genius. The work that first raised him to celebrity was a brazen cow, in the attitude of lowing, and, according to some, of suckling a calf. It was set up

in a public place in Athens, and there it stood till at least the time of Cicero, attracting more notice by its simple truthfulness than all the highly-idealized statues of men and gods that abounded in the thoroughfares and streets of the city. Many authors mentioned it both in prose and verse, and no less than thirty-six of the epigrams in the Greek anthology were written in its praise. The last writer who alludes to its existence is Procopius, in the sixth century. It was then standing in the temple of Peace at Rome. The next most famous work of Myron was the "Discobolus," or quoit-thrower. This athlete is described by Lucian as bending one knee in the act of preparing to play, turning his head slightly to one side, and extending his right hand behind his back to take the quoit from his left. Of this bronze statue many marble imitations were probably taken, in accordance with the custom of that age. Some of these are supposed to have been discovered. One found in the Villa Palombra, on the Esquiline, in 1782, and now seen in the Villa Massimi at Rome, closely agrees with the description of the original given by Lucian. Not so faithful is another that was discovered in the grounds of Hadrian's villa near Tivoli in 1791, and is now exhibited in the Townley gallery of the British Museum. It has both knees bent, instead of one only, and the head inclining forwards, instead of turning round.

The following list of some of Myron's other works is given by Pliny:—A dog; Perseus; sea-monsters; a satyr admiring a double flute; Minerva; Delphic pentathletes; pancratiasts; Hercules; and Apollo. There are also mentioned in ancient authors, a colossal group of Jupiter, Juno, and Hercules at Samos; four oxen, which were placed by Augustus in the portico of Apollo's temple on the Palatine; a statue of Apollo, with the name of the artist in small silver letters on the thigh; Bacchus; several athletes; and a drunken old woman, in marble, at Smyrna.

Myron was also a carver in wood and an engraver in metals. He is said to have died in great poverty, leaving a son, named Lycius, who inherited a considerable portion of his father's talents. (*English Cyclopædia of Biography*.)

MYRRH, a resinous gum which exudes from the bark of the myrrh tree (*Balsamodendron myrrha*, nat. ord. Terebinthaceæ), found in Asia. (See the article BOTANY.) As a balsam, myrrh has been highly prized from the most remote times. We find the earliest mention of it in Genesis xxxvii. 25. The Egyptians used it extensively for embalming their dead, and its sweet odour is easily recognisable in the black bituminous material which is now found in large quantities in mummies. The Greeks and Romans employed it in medicine; and Pliny speaks of it as an important article of commerce in his time, and as selling at a price so high as to provoke extensive and ingenious adulteration. (See Pliny's *Natural History*, Bohn's edition.) Myrrh is now imported from Turkey and the East Indies. That from the former country is considered superior in

¹ *Personal Narrative*, vol. ii., p. 205.

quality, and is easily known from the Indian sort by its paler colour and purer fragrance. It is a true gum-resin, partially soluble in water, and partially in ether or alcohol. It is, however, more soluble in water than in alcohol. Brande gives the following analysis:—Volatile oil, 2·60; resin (soft), 22·24; resin (hard), 5·56; gum (soluble), 54·38; gum (insoluble), 9·32; salts, 1·36; impurities, 1·60; loss, 2·94. It is used in medicine, and enters largely into the composition of tooth-powders; it is also used in incense and other fumigations. Myrrh is packed in chests containing from 1½ to 2 cwt. The quantity imported into Britain in 1856 was 310 cwt. In that year the most inferior East Indian myrrh sold for L.2, 10s. per cwt., whilst the best Turkey brought L.8. (T. C. A.)

MYISIA, an ancient province in the N.W. of Asia Minor, was bounded on the S. by Lydia, on the E. by Phrygia and Bithynia, on the N. by the Propontis and the Hellespont, and on the W. by the Ægean Sea. The name Mysia, however, was often applied to particular parts of this district. The province was divided into five parts,—Mysia Minor, Mysia Major, Troas, Æolis, and Teuthrania. To the first of these the Mysians were originally confined. They had come thither from the country of the Lydians, as Herodotus asserts, or from Thrace, as Strabo maintains, and as their alleged identity with the Mœsians implies. Gradually they spread themselves southward, encroaching upon the Trojans, Æolians, and Phrygian settlers, until they had attained sufficient importance to communicate their name to the entire province. Little is known about their history. They are mentioned by Homer among the allies of Priam. This country was subject at one time to the Lydian monarchy. It then formed in succession a part of the third satrapy under the Persians, and a part of the Syrian empire that was formed after the death of Alexander the Great. On the defeat of Antiochus, the last King of Syria, in 65 B.C., it was given by the Romans to Eumenes, King of Pergamus. It was afterwards incorporated in the Roman province of Asia.

Mysia was rendered rugged by Mount Temnus, Mount Ida, Olympus, and other offshoots of Mount Taurus. There were many rivers, of which the principal were Caicus (*Ak-sou*) in the S., and Æsepus in the N. Pergamum (*Bergaman*), Cyzicus, Abydos, and Adramyttium (*Adramyti*), were the chief towns.

MYSCORE, MAHESURA, or MAISOOR, a raj or native principality in the south of India, under the protection and administration of the British government. It is situated principally between N. Lat. 11. and 15., and is completely surrounded by the British territories subject to the Madras and Bombay presidencies. Its length is estimated at 210 miles, and its average breadth at 140. The country consists of a high table-land, inclosed between the Eastern and the Western Ghauts, and elevated 3000 feet above the level of the sea, from which rise numerous lofty hills, containing the sources of many streams. The principal rivers which intersect the country are,—the Cauvery, Tumbuddra, Vedawati, and the Northern and Southern Penna. The elevation of this inland plain varies at different places. The highest mountains of Mysore, namely, those of Bababudin, near Bednore, rise to the height of 6000 feet; the elevation of Sivagunga is 4600 feet; at the Pass of Peddanaik Durgum the height is 1907 feet, according to barometrical observations; at Baitamangalum, 2435; at Bangalore, 2807; at Hurryhur, 1831. The heat of the climate is mitigated by the height of the ground, and the climate throughout the whole of this extensive tract is remarkably temperate and healthy. This country has another peculiar advantage, namely, that it is sheltered by the Ghaut Mountains from the violence of the monsoons, which sweep along the lower plains, and deluge with torrents of rain the coasts of Coromandel and Malabar. The clouds which are driven on the land from the Indian Ocean by the

south-west monsoons are opposed by the mountain-wall of the Western Ghauts; and although the higher and lighter clouds make their way into the plains, and occasion frequent, and sometimes heavy showers, which refresh the air and the ground, yet they are seldom of long continuance. Occasional showers, however, fall at other seasons, and preserve the verdure of the fields throughout the year.

The country of Mysore, from its elevation and its temperate climate, not only produces all the other grains and vegetables of other parts of India, but also many of the fruits of Europe. It appears to have been formerly in a much higher state of cultivation than at present; but it was nearly ruined, partly by the invasion of armies, partly by the rigorous administration of Hyder, and still more by that of his son Tippoo. It is now rapidly recovering from its depopulation under the sway of the British. Rice is cultivated on the higher and lower grounds; and the cultivation is much aided by means of reservoirs and wells, whence the farmers irrigate their fields and gardens. The soil also produces the sugar-cane, for which the black clayey lands are best adapted. The crop of *raggy*, a species of coarse grain which supplies all the lower classes with their common food, is the most important of any raised on the dry field. Wheat is cultivated in gardens, or in the rich soil of the beds of the tanks, which have been exhausted for the purposes of irrigation. It is only a small quantity, however, that is raised. The *Ricinus communis* is found here, and produces abundance of castor oil, which is used for the lamp and a variety of other purposes. The betel-leaf tree thrives on the low grounds, where it can obtain a supply of water; and the poppy is cultivated, both for making opium, and on account of the seed, which is much used in the sweet cakes that are eaten by the higher ranks of the natives. The cocoa-nut palm begins to produce in this province when it is seven or eight years old. Agriculture is here in a very backward state, and the implements used are very imperfect. The plough has neither coulter nor mould-board to divide and turn over the soil, and it seldom penetrates more than three inches deep. The fields are in consequence very imperfectly cleared; and after six or eight ploughings in all directions, numerous small bushes remain as erect as before the labour commenced. Considerable attention is, however, paid to the manuring of the soil; every farmer collecting a heap from the dung and litter of his cattle, intermixed with the ashes and soil of their houses. The cattle reared are cows, buffaloes, sheep, and the long-legged goat; the native breed of horses here, as in most parts of India, is a small, ill-shaped, vicious pony. Above the Ghauts, asses are much used as beasts of burden. The breed is small, and no pains are taken to improve it. Swine were formerly very common in Mysore, but they were banished by Tippoo from the vicinity of the capital. There are three varieties of sheep—tawny, white, and black. Common salt is found in abundance in many places, and is extracted for domestic or manufacturing purposes. Carbonate of soda is also found amongst the Chitteldroog Hills, mixed with common salt. Iron-ore abounds in different parts, though it is worked in a very slovenly manner. At the iron-works near Chinnarayana Durga, the smelters procure from the one about 47 per cent. of malleable iron, which is, however, very impure. The principal rivers, which have been already enumerated, are all inconsiderable, with the exception of the Cauvery, as long as they continue within the limits of this province. There are many large tanks and reservoirs in the higher grounds throughout Mysore, but there are no lakes. The water in these tanks is always sweet, and preferred on this account to that of wells, which is very frequently brackish. Upon the death of Tippoo Sultan in 1799, the territories of the fallen despot were divided, and the portion now bearing the name of Mysore was allotted to the titular rajah of the same name, the representative of

Mysore.

Mysteries. the race which Hyder Ali had supplanted. During the minority of the rajah the country was prosperously administered; and upon his attaining a competent age for taking charge of the government, an accumulation had taken place in his treasury of nearly three millions sterling. This great sum, however, was speedily dissipated, and the annual income so overstepped and anticipated, that in 1832, confusion, insubordination, and, finally, open rebellion ensued, and the British government were compelled to undertake the entire administration of the territory and its revenues, managing them by a commission. The results have been most advantageous. The Hindu rite of suttee has been

forbidden; the Mohammedan population have settled down to agricultural pursuits; transit duties no longer exist; and in regard to commercial relations with Great Britain, Mysore has been placed upon the footing of a British possession. In 1847 the rajah, to whom a large stipend has been allotted, preferred a claim to be reinstated in his dominions; but it was deemed inadmissible, on the ground of his incompetency for the duties of government. The town of Mysore contains many good and substantial houses. It is surrounded by a rampart and defended by a fort. According to official report, the population of the town amounts to 54,729. It is situated in Lat. 12. 18., Long. 76. 42. **Mysteries.**

MYSTERIES.

MYSTERIES (Greek *Μυστήρια*, a word ultimately derivable from the root MU, a sound produced with closed lips) were ceremonies in ancient religions, conducted secretly, and only in the presence of such as had undergone preliminary rites of initiation. The ultimate origin of such ceremonies is doubtless to be sought for in the nature of religion itself, and the feelings of awe and reverence with which its objects are regarded. For to such feelings is directly traceable whatever part sacerdotal exclusiveness or legislative wisdom may be supposed to have had in their institution and preservation. Mystery, in one form or another, is inherent in religion, and will never disappear from it. Mysterious ceremonies, doctrines, and language, are co-ordinate developments of the same religious feelings. The origin and significance of the ancient mysteries have been the subject of much investigation and discussion. On these points some observations will be subjoined to the following succinct account of the most celebrated of these institutions:—

1. *The Mysteries of Isis and Osiris.*—These two deities, like the reigning deities in all mythologies, are preceded in legend by others. A satisfactory explanation of this fact has not yet been reached; it was formerly the main support of the Euhemeristic theory, and has been plausibly explained by that of successive worships, a theory which has also been applied to the explanation of many of the peculiar features of the myths themselves. It is certain, at all events, in the case of Egypt, that the revolutions in her political history were accompanied by extensive changes in her religious systems, and by the displacement or absorption of the ancient and local deities in a more modern group, and the growth of new myths, in which, doubtless, the historical events attending these changes have been partially reflected. Herodotus states, and his statement is confirmed by the monuments, that the Egyptian gods formed three orders (ii. 145). These three orders are successive dynasties of gods whose reign preceded that of mortal sovereigns. Of these three, the most recent is that of Osiris, whose son Horus is the last reigning god. (Bunsen, *Egypt's Place in Univ. History*, vol. i., p. 357.) These two deities alone, Osiris and Isis, were worshipped over the whole of Egypt, and their mythical history formed the subject of the mysteries.

If actual events, as we have supposed, are partially reflected in the story, the whole has been thrown into the prehistoric and dateless periods of mythology, and has been so interwoven with the ideal and purely symbolic, that the elements are not now distinguishable. Osiris, sovereign of Lower Egypt, is, with Isis, his sister-spouse, the originator of agriculture and the arts of peace and civilization. The cultivation of grain and of the vine, settled life, letters, music, and the fine arts, are owing to him. He sets out on a career of conquest and civilization, leaving the government in the hands of Isis, against whom Typhon, brother and implacable enemy of Osiris, wages war in his absence, but is defeated, and affects reconciliation. Osiris visits

Ethiopia, India, and Greece, and introduces a new order of things. On his return to Egypt, he is surprised by Typhon at a peaceful banquet, and put into a coffer, which is committed to the Nile. Isis, learning this, searches for his body, and is guided to Biblos in Phœnicia. Her adventures here present a remarkable similarity to those of Demeter at Eleusis; she becomes nurse in disguise to the son of Astarte, the Queen of Biblos. At length she declares herself, gains possession of the coffer, and returns with it to Egypt, where she conceals herself with it. It is discovered by Typhon, who cuts in pieces the body of Osiris, and scatters it over the country. Isis again sets out in quest of the body, and succeeds in finding all the pieces but one, which she replaces with an artificial phallus, and inters the body at Pousiri. According to other legends, she consigns each piece to a separate tomb, in the form of a human body, so that it is impossible afterwards to dishonour them. Horus defeats Typhon and makes him prisoner, but Isis sets him at liberty and banishes him. Of the ceremonies to which this myth corresponds our information is vague and imperfect. They seem to have been six in number, and celebrated at different periods of the year. 1. The Aphanism, or disappearance of Osiris, on the 17th of Athyr (13th Nov.) 2. The Zetesis, or search for Osiris, about the winter solstice. In this ceremony, the sacred cow, symbol of Isis, was led seven times round the temple. (Plut., *De Is. et Osir.* 52.) 3. The finding of Osiris in January. 4. The burial. 5. The resurrection of Osiris. And 6. In March the entrance of Osiris into the moon. At Abydos and Philæ, supposed tombs of Osiris, were celebrated mystic rites, of which we have no certain information. These ceremonies throw considerable light upon the meaning of the legend. Osiris was the active, life-giving power; hence the sun, the Nile, &c., and hence his symbol, the bull: Isis, the passive, life-receiving power; hence Egypt, the earth, vegetation, &c., and hence her symbol, the cow. The life-giving power suffers in the course of the year a temporary death, but is restored to activity again in the vernal season. The Egyptian mysteries of Isis are to be distinguished from those of maritime Isis, established at Corinth, and afterwards so notorious at Rome. We have a description of these mysteries, doubtless embellished by the author's fancy, in the *Metamorphoses* of Apuleius (lib. xi.) The festival was preceded by purification in the sea before sunrise, and at sunrise a procession was formed, in which the sacred coffer and image of the goddess was borne by a train of priests to the shore, when a curiously-adorned vessel was consecrated. The ceremonies of initiation were practised by night. The neophyte, after various lustrations and instructions, was led into the presence of the goddess, and there heard and saw what he dared not reveal. The discourse put by Apuleius in the mouth of Isis is a commentary on the inscription of Sais,—“I am all that has been, is, and will be.” The advantages

Mysteries. to be derived from initiation were, length of life, the protection of the goddess, and a happy lot in the next world. The worship of maritime Isis seems to have been introduced into Rome about the time of the empire, and was for a long time held in contempt and detestation. This feeling doubtless facilitated the degradation of these mysteries into what they became under the later emperors,—scenes of debauchery, and all kinds of wickedness. (See Ste Croix, *Recherches*, &c., vol. ii., p. 172.)

2. *The Mysteries of Demeter, of Dionysus, and of the Cabiri.*—While the history and mythology of Egypt cannot be said to be as yet completely deciphered, we have, on the other hand, very full and exact information on the mythology and worship of Greece. In Greece every deity had his peculiar mysteries; Jupiter, *e.g.*, had a mystic worship in Crete, Juno in Argolis, Hecate in Ægina, Diana in Arcadia, &c. The most celebrated of all, however, were those of Demeter at Eleusis in Attica. They owed their fame, doubtless, to the city in which they were celebrated, the influx of cultivated strangers into Athens, and partly also to the nature of the myth itself, of which they were a kind of commemorative representation. The myth, whose most ancient form is preserved in the Homeric hymn to Demeter, is well known: it is that of the wanderings of Demeter in search of Persephone, carried off by Aidoneus (Pluto); her arrival and disguise at Eleusis; her final recovery of her daughter; and her institution of agriculture, arts, laws, and civilized life; according to one legend also, of the mysteries themselves, to the participants in which her protection and the favour of Persephone, queen of the under-world, were secured. The mysteries of Demeter were originally peculiar to the Eleusinians, and were conducted by the Eumolpidae; when Eleusis became subject to Athens, it was stipulated that they should always continue to do so. Thus, while Athenians were initiated, the superintendence of the festival was in the hands of that family, under the second Archon (Basileus), and associated with the Ceryces (originally of the same family), and with the female descendants of King Celeus. The Hierophantes and the Dadouchos were the chief ministers; the latter had charge of the purifications. Among the inferior offices an important one was that of Exegetes, or interpreter. The Eumolpids had also an authority, subject to appeal, in all matters of sacrilege. The cases of Diagoras (Lysias, *Con. Andoc.*), of Aristotle (Diog. Laert. v. 1), and of Æschylus (Aristot., *Eth. Nicom.* iii. 2), prove the strictness with which the laws were enforced, and the jealousy with which the mysteries were guarded from profanation. (See also Liv. xxxi. 14.) The less and the greater mysteries must be distinguished; the former, held at Agra, on the Ilissus, in the month of Anthesterion (February), consisted mainly in preparatory purifications by the sacrifice of a sow; an oath was administered to the *mystæ*, as they were called, at this stage, and instructions given them. The great mysteries were celebrated in the month of Boedromion (September), probably nine days (15–23). The first five days were occupied with various lustrations; on the sixth a grand procession was formed, bearing the statue of Iacchus from the Eleusinion in Athens to Eleusis, and on the night of this day the last initiation was performed. Proclamation being made by the Hieroceryx commanding the profane to withdraw, an oath was exacted, mystic questions put (the better to prevent intrusion), further purifications practised, and the recesses of the temple were disclosed to the *Epoptæ*. It would appear, from various allusions in ancient authors, that the punishments of the under-world were represented, as the myth required, and probably also the nuptial union of Aidoneus and Persephone. This latter scene, with certain others of a similar kind in the other mysteries, perhaps gave colour to the charges of immorality brought against them by later, especially Christian, writers. These scenes were fol-

lowed by the *autopsia*, a kind of beatific vision, of which we have no clear account, and which appears to have been accompanied by a prescribed discourse from the hierophant, and then the assembly was dismissed with the mystic formula *Konx, Ompax*, repeated by the audience.

Connected with the Eleusinia were the Thesmophoria, a mystic festival celebrated by the Attic women alone, 14–18 Pyanepsion (October), and which derived its name from the procession to Eleusis on the last day, in which the laws were solemnly carried. These mysteries were also held during the night; were prepared for by continence, fasting, and lustrations; and appear to have had reference to the supposed institution of laws by Demeter.

The mysteries of Dionysus were also celebrated by women alone, in the month of Anthesterion, in the temple of Dionysus *or* *Διονυσος*. They were presided over by the wife of the Archon king (Basilissa), assisted by fourteen priestesses, called *gerææ* (venerable), to whom she took an oath that she was pure and unpolluted, and with whom she offered mystic sacrifices for the welfare of the city. The *mystæ* wore skins of fawns, and myrtle, instead of ivy. The sacrifice was a sow, as in the mysteries of Demeter. When these mysteries were introduced into Rome, they speedily degenerated into shameful immoralities; men, as well as women, were initiated; they were held five days in every month; and such were the crimes and excesses committed, that they were at length suppressed by a *senatus consult* B.C. 186. (Liv. xxxix. 8–18.)

The names, nature, and origin of the Cabiri are perhaps the most obscure points of Greek mythology. The etymology of the name itself has been the subject of much conjecture. This much appears certain, that the deities worshipped as Cabiri in Samothrace and Lemnos were the gods of an ancient Pelasgian people of the same name, and had relations with the most ancient seat of the Pelasgian worship in Northern Greece. The mystic names of the Cabiri were “Axieros,” “Axiokersos,” and “Axiokersa,” to whom a fourth, “Cadmilus,” is sometimes added. But to what Grecian divinities these names corresponded the conflicting testimonies of ancient authors leaves us in entire ignorance. This conflicting testimony has given rise to the conjecture of successive epochs in the Cabiric worship, the last being that in which the Cabiri were confounded with the Dioscuri, and became nothing more than mariner-preserving deities, their former attributes being lost in a haze of tradition. (St Croix, i., p. 44; Limburg-Brouwer, *Hist. de la Civilis. des Grecs*, iv., p. 352.) At all events, preservation from the dangers of the sea came to be the main object of initiators in the mysteries of Samothrace. The initiated were furnished with amulets for this purpose. Of the rites observed in these mysteries nothing certain is known. The myth of the murder of Cadmilus by his brothers appears to have been represented in them.

3. *The Worship of Mithras*, its origin, rites, and meaning, are extremely obscure. (Creuzer, *Symbolik*, ii., p. 193, ff.; Seel, *Mithrageheimnisse*, 1823; Ste Croix, *Recherches*, ii., p. 121.) In the *Zendavesta*, Mithras is the chief of the Izeds, under Ormuzd, who is his creator, and in whose war against Ahriman he is the presiding agent. He covers the earth with fruits and verdure, dispenses light and heat in nature, and guards men from the attacks of Ahriman; he is the judge of man in a future state, one month in the year is consecrated to him, and the sixteenth of every other. He is to be invoked thrice a-day. When the mystic worship of Mithras spread from Persia into Asia Minor with the Medo-Persian power, and afterwards, under the Hellenic monarchies, into Alexandria, and under the Roman empire into Rome and Europe, the original Persian idea was altered. Mithras was confounded with the sun and the supreme deity, and practices were adopted—celibacy and fasting, *e.g.*, partly, it is probable, from the Christian religion—quite inconsistent with the Persian worship. We hear of it first

Mysteries. in Rome at the close of the first century, under Trajan. Monuments have been found in Italy, in the Tyrol, and other parts of Europe. On these, Mithras is represented as a young man plunging a sacrificial knife into a bull on which he is seated, and surrounded with mystic, sometimes clearly zodiacal figures,—a physical emblem, it has been held, of the reproductive forces of nature, from year to year bringing life out of death; and a moral emblem of the ever-repeated victory of the good over the evil principle. Nor is there in this duplicity of signification anything repugnant to the spirit of ancient mythology. Mithriac initiation was protracted and severe. The neophyte was baptized, anointed on the forehead, and received bread and wine; a crown was placed on his head, which he rejected with the words, "Mithras is my crown;" and finally he received a sword, and was declared, "soldier of Mithras." This was the lowest grade; the others had mystic names derived from animals sacred to the god.

The discussion respecting the Grecian mysteries has chiefly turned upon the question, what esoteric religious doctrine they were meant to conceal and convey?—a question which should surely have been preceded by the inquiry, whether they were meant or employed to convey any doctrine at all? The former question has also been constantly confounded with another, and a very different one, viz., What is the real import of the myths with which these ceremonies were connected?—it having been assumed, without satisfactory evidence, that the myths, and their interpretation into abstract terms, were handed down together, the former having been invented as a cloak for the latter, to be removed only to a select few, under the strictest bond of secrecy. In the first place, such a notion—and any theory of an esoteric doctrine involves it—is opposed to sound views of mythology. Such explanations are not possible beside the still living and credited myth; a myth not being the secondary but the primary expression of religious thought in the period which produced it,—the spontaneous and living form of the idea. Secondly, the theory of an esoteric doctrine is opposed to a sound criticism of the facts. On the introduction of Christianity, the philosophic adherents of polytheism interpreted the mysteries in an ethical and spiritual way; probably they attempted to modify them in accordance with their views, and largely appealed to those explained and reformed ceremonies in reply to the accusations of immorality and absurdity brought against polytheism and its institutions. The mysteries became in their hands points of contact between philosophy and the popular religion; and by this means what were at first simply secret ceremonies connected with secret symbols, acquired arbitrary significations of profound import,—descent of the soul into union with matter, &c. But when we ascend to earlier writers, we find that every one attempted to allegorize or euhemerize the myths which underlie the mysteries in his own fashion, just as the other myths were dealt with, and that these discordant explanations are frequently without hesitation attributed to the secret tradition revealed to the initiated alone. (Limburg-Brouwer, iv., p. 287.) This of itself is sufficient proof that there was no esoteric tradition at all; nor is there any evidence that the instructions given to the initiated were anything more than the necessary information as to their conduct during the ceremony. The supposed necessity of finding a concealed doctrine has given rise to many singular theories, of which one or two of the most remarkable may be noticed. According to Warburton (*Divine Legation of Moses Demonstrated*), the mysteries had three objects: 1. To commemorate the origin of civilization. 2. To inculcate the doctrine of future rewards and punishments. 3. To reveal the doctrine of the unity of God. In this last consisted the real secret doctrine, and it was revealed only in the great mysteries, to which access was as difficult and rare as

it was frequent and easy to the less. On this last assertion,—**Mysteries.** destitute of all proof, and opposed to everything certainly known of the matter,—and on the further reasoning, that though the revelation of such a doctrine would be fatal to the popular system, it would not affect the worship of beings intermediate as to man and the Deity,—he relies to obviate the invincible objection that polytheism and such mysteries could not have existed together. The paradox reaches an extreme when it is alleged, that legislators established ceremonies subversive of the public religion, for the purpose of furnishing stronger bonds of social faith and order. The uncritical way in which, to support his theory, Warburton treats his authorities, has been ably exposed by Leland, Ste Croix, De Sacy, and Limburg-Brouwer. Ste Croix, while rejecting Warburton's theory, that the secret doctrine of the mysteries was the unity of God, is at one with him in regard to the special moral and religious aims which he attributes to them. According to that learned writer (*Recherches Hist. et Crit. sur les Mystères du Paganisme*, 2de édit., par Silvestre de Sacy, Paris, 1817, 2 vols.), they were instituted by the early legislators to commemorate the blessings of civilization, and, further, to furnish expiation for crimes. The germ of the mysteries is lustration and expiation; the doctrines taught were, the necessity of repentance and confession, the immortality of the soul, and a future state of rewards and punishments. The views of the editor of that work, Silvestre de Sacy, are more sound: there was no secret doctrine in the mysteries; certain rites and symbols were secret, and these it was sacrilege to reveal. Theories of explanation and allegory may have found their way from the schools of philosophy into the celebration of the mysteries; but it is utterly erroneous to conceive that any philosophical doctrines had their origin there. Creuzer (*Symb. u. Myth. der alten Völker*, iv., p. 512, ff.) has delivered himself, with little reservation, to the reveries of the Neo-Platonists. Egyptian priests introduced their doctrines into Greece under the veil of the mysteries, instructing the few, who, by submitting to the necessary probations, showed themselves worthy of being instructed in the doctrines of the unity of God, the immortality of the soul, its emanation from the Supreme, &c. When Christianity commenced to threaten the ruin of polytheism, the philosophers at length resolved to betray the great secret which had been concealed for ages in the rites of Eleusis and Samothrace. Perhaps the extreme in this exaggerated estimate of the mysteries has been reached by Schelling. His positions are (*Philosophie u. Religion*, p. 75; comp. Wegscheider, *De Myster. Græcorum Religioni non obtrudendis*, Göttingæ, 1805), that the doctrine taught in them was in the directest opposition with the public religion, that this doctrine included a pure monotheism, and that Christianity is only the publication of their secret. According to F. C. Baur (*Symb. u. Mythol.*, tom. iii., p. 159), the fundamental idea of the mysteries is that of a god (representative of nature and humanity) who suffers and dies, and who afterwards triumphs over death, and has a glorious resurrection. The mystic doctrines included sublime doctrines of cosmogony, of immortality, palingenesis, and of the most refined pantheism. Ouvaroff (*Essai sur les Mystères d'Eleusis*) has maintained that the initiated "not only acquired just notions on the Deity and his relations to man, on the primitive dignity of human nature and its fall, on the immortality of the soul, and the means of its reconciliation with God; but that oral and even written traditions were revealed to them,—precious remains of the great shipwreck of humanity." Heeren (*Ideen*, &c., vi., p. 76, ff.) maintains generally that the mysteries were instituted to preserve the symbolico-physical signification of the gods of paganism, which without them would have been lost. As already observed, such theories have their origin in the imagined necessity of finding something worthy, in modern conception, of concealment in the

Mysticism, ancient mysteries, and derive their support and plausibility from an uncritical confusion of times and authorities. Already Mosheim (Notes to Cudworth, *Intell. Syst.* i., p. 329) and others had taken a more rational view of the subject; but the main credit of introducing sound criticism into the whole discussion is due to Müller, who, in his *Prolegomena to a Scientific Mythology*, first clearly enunciated a principle destructive of the fundamental fallacy of these theories, and especially to Lobeck (*Aglaophamus*, 1880).

MYSTICISM is that form of error, whether in religion or philosophy, which mistakes the operations of a merely human faculty for a Divine manifestation. All men, it has been said, are born either Platonists or Aristotelians; and there can be no doubt that the mystical tendency finds a legitimate origin in human nature. It is always a protest—if frequently a blind one—in behalf of what is highest and best in human nature; and its voice is continually heard in an age of formalism and moral degradation. It is a reaction against a spirit of scepticism, and is fostered by that weariness of the world, that shrinking from conflict, and passionate longing for inaccessible rest, which the crushed and timid spirit so frequently displays. The fascination of mystery, also, which attends all forms of this spiritual development, exerts a powerful influence over the earnest imagination.

Classification of mystics.

Mystics have been divided into the three classes of—*Theopathic*, *Theosophic*, and *Theurgic*. The theopathic mystic resigns himself with more or less passivity to an imaginary Divine manifestation; and in proportion to the degree of this passivity he becomes either a contemplative quietist, who regards himself as overshadowed by the Deity, like Suso, Molinos, or Madame Guyon; or, believing himself to be impelled by Deity, assumes a more positive and active attitude, like Tanchelm, Gichtel, or Kuhlmann. The theosophic mystic, again, aims at scientific rather than practical results, lives to know rather than to act, and believes himself to be possessed of a certain supernatural divine faculty for theorizing about God or his works. He either believes, with Swedenborg and Behmen, that the mysteries of the Divine dispensations have been disclosed to him by a special revelation; or holds, with Plotinus and Schelling, that his intuitions of the hidden processes of nature and the secrets of the universe are infallible, because Divine; being the result of an identification of the subject and object of thought. But while the theopathic mystic is content to feel or proselytize, and the theosophist to know, the theurgic mystic aspires to hold converse with the world of spirits, and secure the prerogative of working miracles. As claimants to this supernatural power, Apollonius of Tyana, Peter of Alcantara, Asclepigenia, and St Theresa, all rank as religious magicians.

**Oriental
mysticism.**

As mysticism is the spontaneous product of certain crises in individuals and societies, it consequently presents no proper development, whether traditional or systematic. Its main characteristics are constantly the same, whether they find expression in the *Bagvat-Gita* of the Hindu, or in the writings of Emmanuel Swedenborg. The earliest mystics known are those of India, and the best exposition of their system is to be found in the heroic poem of the *Bagvat-Gita*. (See Wilkins's translation.) They lay claim to disinterested religious feeling, repel the lifeless formalism of the Vedas, pantheistically identify subject and object, and aim at ultimate absorption in the Infinite. To effect this dissolution, they inculcate an absolute cessation from all activity, and prescribe certain recipes for obtaining this Divine trance, believing that eternity may thus be realized in time. They lay claim also to theurgical powers, and counsel the neophyte to give absolute submission to his *guru*, or spiritual guide. This guru is a representative

and Limburg-Brouwer (work cited). The value of their investigations is not inseparable from the positive theories they have advanced on the particular origin of secret worship and initiation (Müller, for example, conjectures that they arose from the attempt by a conquered race to preserve their ancient worship), but consists in having put an end to the unfounded speculations as to an esoteric traditional doctrine, which so long rendered the subject, already sufficiently obscure, a wilderness of perplexity. (W. H. C.)

and vehicle of Divine power, the principle worshipped by the Hindus, and finds its parallel in the Pir of the Sufis, the middle-age Confessor, and the Directeur of modern France. (See Southey's *Curse of Kehama*, Notes.)

The second chronological stage of mysticism is that of Neo-Platonism. The Neo-Platonists of Alexandria, which combines, for the first time, the leading fundamental ideas of the system with the purer and more exalted conceptions of Christianity. Philo was the intellectual father of Neo-Platonism, and he laboured to combine the high monotheism of the Hebrew Scriptures with the doctrines of Plato. From amidst the licentiousness and heartless scepticism of that great commercial Babel, arose the asceticism of the Therapeutæ—a sect who sheltered themselves in secluded cells, and by fasting and contemplation sought for divine illumination around the remote shores of the Lake Mareotis. Of this sect Philo has left us an account in his *De Vita Contemplativa*. The ostensible founder of this school of Neo-Platonism was Plotinus, who, at the age of twenty-eight, began the study of philosophy in Alexandria A.D. 233. Its greatest names, after Plotinus, were Porphyry, Iamblichus, and Proclus, who is the last of the distinguished thinkers among the Alexandrian eclectics. The requisite information respecting those men will be found under the name of each. (See HYPATIA, and ALEXANDRIAN SCHOOL; also Kingsley's *Alexandria and her Schools*, and *Hypatia*.)

We next come to the reign of mysticism in the Greek Church—to the hermits, saints, and fathers of the desert. (See MONACHISM.) The most noteworthy of these was St Anthony, who flourished during the latter part of the third and the beginning of the fourth century; Macarius, who retired to the deserts of Nitria in the fourth century; and the pseudo-Dionysius, called the Areopagite, who committed the literary forgery of the Platonized theology which goes by his name, and which must have been written about the middle of the fifth century. Among the anchorites of this period are to be found all the theurgic pretensions of later, and especially of mediæval times. (See ANTHONY, *St*; and DIONYSIUS *the Areopagite*.)

Gradually the eastern mysticism moved westward, and in the found itself transplanted into a region of great intellectual Latin activity, such as it had not known before. Neo-Platonism, church. while acting as a soporific on the moral activities of the East, became a life-giving principle when transplanted to the West. Platonism and mysticism combined in creating a party in the church who were the sworn foes of scholasticism, empty dogma, and hollow quibbling, and who used all their efforts to check the growth of clerical abuses and ecclesiastical pretension. With the mystics of the Latin church monasticism was the avowed panacea. The most distinguished names of this development of mysticism are those of St Bernard of Clairvaux, and Hugo of St Victor, both born during the last years of the eleventh century ; also Richard of St Victor, the Scottish pupil and successor of Hugo, a man who possessed all the *perfervidum ingenium* said to characterize his countrymen in those early days. The great business of St Bernard's life was to found and organize convents : the ruling principle of his theological teaching is faith. Reason he all but dethroned, and gave the most vital interpretation to the *credo ut intelligam* of

Mysticism. St Anselm. All doubt was with him the sure sign of a depraved heart, and any divergence from the acknowledged standard of piety unspeakably criminal. He maintained the fundamental maxim, *invisibilia non decipiunt*, of the religio-philosophy of the middle ages to its fullest extent. Knowledge with him was an illumination depending on the state of the heart, and resulting from an essential relationship to the divine source of ideas. Sense and experience were set aside, and the Scriptures were studied, not for their practical teaching, but with an eye to discover in them all manner of absurd symbolisms and recondite abstractions. In this respect Bernard only resembled the whole of the speculators of that period. The mysticism, however, of this distinguished abbot displayed a great degree of practical moderation. If he attempted to transcend humanity as the theosophist, in his zealous advocacy of the humbler Christian virtues and in his loud protest against a life of contemplative sloth, he ranks with the better class of those theopathic mystics who have laboured to better their race and purify the world. But while the system of Bernard repudiated scholasticism, that of the St Victor school strove to reconcile it with mysticism. This combination is also visible in all the strictly mystical theology of the middle ages, and it is abundantly exemplified in Bonaventura, in the thirteenth, and Gerson, in the fifteenth century. (See in particular Liebniz's *Hugo von St Victor und die Theologischen Richtungen seiner Zeit*; also Engelhardt's *Richard von St Victor*.)

German mysticism.

We find ourselves introduced to the German mysticism of the fourteenth century by the Chronicle of Adolf Arnstein, the pious armourer of Strasburg; by Hermann of Fritzlar and his legends; and especially by the notable preacher Master Eckart. What was most peculiar in the mysticism of the latter, as contrasted with the ordinary ecclesiastical and scholastic aspects of that system, was the peculiar emphasis which he bestowed upon "our own consciousness of being the sons of God." Eckart felt that the church could not afford him a secure resting-place for his soul; and he accordingly supplied one for himself in a strange agglomeration of pantheistic metaphysics, which formed a bold and fervid reaction against the orthodox externalism of his time. His theosophy forms a striking anticipation, in some respects, of the idealism of modern German speculation. Hegel calls the system of Eckart "a genuine and profound philosophy;" and there is certainly often a strong resemblance between the doctrines of the Dominican and those of the advocate of the *Logische Idee*. To this period also belong John Tauler; the author of the famous *Theologia Germanica*; Henry of Nördlingen; Nicolas, the layman of Bâle; the Friends of God; the Flagellants; Ruysbroek; Suso; the Monks of Mount Athos; the pious ladies Brigitta, Angela de Foligni, and Catherine of Siena; also Thomas à Kempis, author of the celebrated book *De Imitatione Christi*; and the eminent Frenchman, Chancellor Gerson. But unquestionably the most remarkable of that earnest group of German mystics was John Tauler. He was a man of profound reverence and fervidly pious spirit, who frequently trod upon the verge of the pantheistic abyss of Eckart, but never fell into it. So emphatically does he insist upon total self-abnegation, and the annihilation of everything human in us, that our very fixitude seems almost criminal in his eyes, and the possession of individuality something bordering on a sin. To deify man, he would strip him of his humanity: he would divorce the higher faculties of the soul which ally man to God, and those inferior powers which belong to a lower sphere, rather than strive to harmonize them by assigning to each its legitimate functions. But in spite of the numerous contradictions of his negative theology, he was himself an eminently spiritual and fervently pious man. The theurgic and sensuous element of mysticism, such as apparitions, voices, &c., find no place with him; and he cer-

tainly rose farther than any of his fellow-mystics above the peculiar dangers of the system. He was a genuine pioneer of the Reformation, and Luther's admiration of him is well known. (See TAULER; also Pfeiffer's *Deutsche Mystiker*, Leips. 1857.)

Mysticism was not, however, limited to the West, and to Persian Christian communities, during the middle ages; we find a genuine development of this mode of thought and feeling among the poetical effusions of the Persian *sufis*. It might at first sight seem almost an impossibility for mysticism to find any nourishment under the unfriendly shade of the Koran, with its detailed ritualism and cold formality; but, as so often happens, the wants of the human heart prove too strong for creeds, no matter how rigid. At a very early period in the history of Mohammedanism a class of persons gradually arose within its pale who dared to set aside the letter in behalf of the spirit of the Koran. Witness the devout ardours of the female saint named Rabia, who appeared about the end of the first century of the Hegira, and who, in her self-abnegation and disinterested devoutness, bore such a marked similarity to Madame Guyon; and unquestionably some of the brightest names associated with the literature and religion of the false Prophet are found to have been deeply imbued with the genuine mystical spirit. The name generally applied to the mystical asceticism of the Mohammedans is *sufism*. The *sufis* lay claim to a supernatural intercourse with the Deity, to a mystical union or identity with the Supreme, bringing with it theurgic powers. The name has a very extensive application. It is given alike to poets, philosophers, dervises, and fanatics. Persia is the great centre of *sufism*, and in its *sufi* poets mysticism has achieved a success unknown in any country of Europe. The only western *sufi* which mysticism has known was Angelus Silesius, the author of the religious poem, the *Cherubic Wanderer*. He flourished during the seventeenth century, and assumed the name of Angelus; but his real name is not known. It is pretty obvious that it was not John Scheffler, as some have supposed. (See, under this branch of the subject, Tholuck's *Sufismus, sive Theosophia Persarum pantheistica*, Berlin, 1822; Tholuck's *Blüthensammlung aus der Morgenländischen Mystik*, Berlin, 1825; Schrader's *Angelus Silesius und seine Mystik*, Halle, 1853; and Sir William Jones, *On the Mystical Poetry of the Persians and Hindoos*.)

It has already been remarked, that not a few of the mystics who preceded the Reformation were genuine reformers; and it cannot be doubted that the way for that grand religious emancipation was in great part prepared by the mystics of the fourteenth century. So long, however, as the standard of truth was internal and subjective, and was very much at the caprice of every fresh dreamer who chose to elaborate a scheme of cosmology, or invent new rules for the regulation of the religious life, a thoroughgoing reformation of the existing abuses of the church remained impossible. Luther, however, saw into the mistake; and while he sympathized constantly with what was highest and truest among the mystics, he nevertheless endeavoured to supplement their honest efforts by the important announcement, that the Scriptures were the sufficient standard of truth. The more clear-sighted and courageous among the mystics at once hailed the new doctrine as light from heaven; but there remained still a party among them who began by suspecting, and ended by despising, that which alone could have saved what truth they had from utter oblivion. The mystic of the sixteenth century accordingly did what he could to retard the progress of the Reformation. Examples of this sort are only too numerous; and Luther had to contend at the very threshold of his great undertaking with the stupidity and wilfulness of these deluded spiritualists. When holding a public discussion on one occasion with the mystics Stübner and Cel-

Mysticism. *larius*, Luther called upon the latter to substantiate his positions by a reference to the Scriptures; but the self-sufficient schoolmaster replied, after stamping frantically, and striking the table with his fist, that it was "an insult to speak so to a man of God." The most noted of these spiritualists were, Dr Bodenstein of Carlstadt, the crotchety little professor of Wittenberg; the prophets of Zwickau—Frank the pantheist, Schwenkfeld the pietist, and the silent, earnest Valentine Weigel, who combined the theopathic and theosophic schemes of Schwenkfeld and Paracelsus, and thus prepared the way for Jacob Behmen. The majority of the mystics, posterior to the Reformation, were of the theosophic class, of which the principal examples are to be found in Cornelius Agrippa, Theophrastus Paracelsus, and Behmen, all of whom will be found under their respective names in the present work. The mystics of a former time were content to seek a union with Deity by ignoring his works, and found their highest knowledge in supreme obliviousness of all sensible things; but now the current of thought took a different turn, and nothing short of a supernatural knowledge of the recondite mysteries of creation, such as was not vouchsafed to ordinary mortals, could satisfy the immoderate desires of this unworldly fraternity. The most distinguished name of this class was unquestionably Jacob Behmen or Boehme, the blue-eyed, gentle-voiced old shoemaker of the little town of Görlitz, born in the year 1575. A genial, manly mystic withal was this withered little shoemaker; free from everything effeminate and sentimental; a genuine Protestant, and stanch Lutheran; but intensely speculative and imaginative. He addressed himself more to the learned than to the lower orders, and his teaching doubtless supplied a real want of those times, inasmuch as Lutheranism was beginning to harden and wax cold, and the current orthodoxy was giving symptoms of a growing literalism and harsh formality hostile to the development of the true life of the soul. His whole life resembled one great dream; but he strove with as much zeal as ever man displayed to benefit his fellow-mortals and exalt the name of God. (See BEHMEN.)

The Rosicrucians.

Early in the seventeenth century the mysterious order of the Rosicrucians began to make a noise in Germany. A young Lutheran divine of great zeal and courage, named Valentine Andréa, is generally believed now to have been the author of that far-famed little book, published in Germany in 1610, entitled *The Discovery of the Brotherhood of the Honourable Order of the Rosy Cross*. In it he calls upon the learned and devout everywhere who desire to lend their assistance in diminishing the amount of human suffering, ignorance, and moral degradation, immediately to advertise their names. He indicated, however, neither name nor place of rendezvous, but threw out his little anonymous book as a feeler, by which he might ascertain the number of right-minded men who would freely co-operate with him. But superstition was rampant at the time, and the amiable hoax of the young divine proved fertile in fostering some of the very errors he wished to put down. No society, it is believed, was ever actually formed; yet the name Rosicrucian (*rosa, crux*) gradually became a generic term, denoting every kind of occult skill, whether of arcana, elixirs, theurgical symbols, or the philosopher's stone. From this singular origin accordingly sprung in a great measure the secret societies—freemason and otherwise—of the succeeding century. The grand Rosicrucian lodge apparently existed nowhere but in the brains of the superstitious; yet men talked of its secrets with bated breath, and orthodox divines groped in blind wrath for the pillars of the Rosicrucian "Temple of the Holy Ghost." (See *Ueber den Ursprung und die Vornehmsten Schicksale der Orden der Rosenkreuzer und Freymaurer*, von J. G. Buhle, Gött. 1804; also Sir E. B. Lytton's *Zanoni*.)

The opposition offered to the principles of the Reforma-

tion by the Church of Rome found its highest development in Spain. There blossomed the flower of fanaticism—there flourished that chivalry of persecution which gloried in shedding the blood of the heretic, and in multiplying the horrors of the Inquisition. Among those zealous luminaries none shine so bright as Ignatius Loyola, St Theresa, and John of the Cross. The two latter were pre-eminently mystics: Rome recognised in Theresa her queen of seeresses, and in John her prince of ascetics. The one was a theurgic, the other a theopathic mystic, and both carried the peculiarities of these schools to their highest expression. During the previous centuries, particularly the fourteenth, mysticism and freedom of thought were well nigh synonymous; but in the sixteenth and seventeenth the mystical tendency was shown no quarter, unless it proved subservient to the cherished designs of the church in checking the growth of the Reformation. Accordingly, the doctrine of blind obedience to ecclesiastical authority became not only a capital article of faith with the mystics hostile to the Reformation, but formed the ruling principle of their entire lives. Formerly the mystic breathed his deepest emotions in the ear of the Supreme alone; now he must adapt his aspirations to the ear of his confessor, and allow no yearning of the heart, however sacred, to ascend directly to the source of consolation. Appeal to the director or confessor is constantly urged in the writings of Theresa and John; and nothing but "the blackness of darkness of despair" is held in store for those who would in jot or tittle renounce the guidance of that stern functionary. The mysticism, however, of little John of the Cross was of a much more elevated character than that of his saintly contemporary. Nor was he guilty of the pious lies and mean cruelty by which not a few of his zealous coadjutors sought to bring honour to their church.

Mysticism.
Spanish
mysticism.

This species of slavish mysticism was not destined to Quietism.

remain long without modification and even direct opposition. The mystical system known as *quietism* came into notice during the seventeenth century, and especially about the beginning of the eighteenth. This system was a virtual protest against the mercenary religion of the consistent Romanist, and opposed the unnaturally refined doctrine of "disinterested love" to the vulgar commercial machinery in which superstition delighted to indulge. Thus the extreme of nominalism and insincerity gave birth to the opposite extreme of spiritual "perfection" and complete sanctification by faith. The pure spiritual flame which burned in the heart of Madame Guyon scorched the band which bound her to her director, and she learned to prize the "prayer of silence"—the yearning, unutterable language of the soul—as immeasurably superior to those so-called prayers repeated by rote in the oratory at the behest of a spiritual guide. As contrasted with the sensuous theurgy of St Theresa, the benevolent quietism of Madame Guyon appears to decided advantage; yet Rome rewarded the fair devotee of Spain with the honour of saintship, while her no less saintly sister of France was constituted a female confessor. (See GUYON.) But, as might have been expected, the encroachments of quietism on the exclusive prerogatives of the Romish clergy were not to be borne with equanimity. Madame Guyon and Molinos were both incarcerated as dangerous enthusiasts, as indeed little John of the Cross had been at the outset of his career. The leader of quietism in Italy was Michael de Molinos, a Spaniard of enlightened piety and blameless life, who was held in high favour by the Pope himself, and who had his abode in the Vatican. He maintained doctrines similar in substance to those of Madame Guyon, and published a book called *The Spiritual Guide*, with the sanction of four inquisitors, in 1675. The dangerous tendencies of these doctrines were soon found out by the ruthless zeal of Louis XIV. and his Jesuit counsellors; and as there was more of the religion of the heart than of

Mysticism. the rosary in Molinos' book, its pious author was, by their influence, condemned to spend the remainder of his days amid the gloom and solitude of a dungeon. A similar fate accompanied the closing years of Madame Guyon. From his connection with St Cyr as one of the directors, and with Madame Guyon, whom he met there, the gentle Fénelon became tainted also with the quietist heresy, and his vain, imperious brother Bossuet pursued the most tortuous courses to involve the good man in disgrace. The "eagle of Meaux" prostrated himself with frantic theatricality at the feet of royalty, when Fénelon published his *Maxims of the Saints* in 1697, and with an affectation of tears implored pardon for not previously disclosing the wicked heresies of his wilful brother. This scene was followed by a great flight on the part of the "eagle," termed *An Account of Quietism*, in which he assailed poor Fénelon and his very moderate admixture of mysticism with the most ruthless violence. A meek and triumphant *Reply* was elicited from Fénelon, *Remarks* from Bossuet, a fresh rejoinder to the *Remarks* from Fénelon, and the controversy came to an end. Louis urged the interference of the Pope to crush the heretic of Cambray: infallibility was constrained to submit to Louis, and Fénelon to succumb to infallibility. The Pope's sentence was pronounced in 1699, and the submission of Cambray is famous in history. (See FÉNELON.)

English
mysticism.

Unlike the other countries of Europe, Britain was not prepared for the Reformation by the teachings of mysticism. Wycliffe of England, "that morning star of the Reformation," shone with quite a different lustre from the dim, unsteady light of the fervid German Tauler. Indeed, English soil generally does not seem to be favourable to the growth of that delicate plant, mysticism, which always vegetates best where the light is dimmest. English mysticism, if not always sober, is seldom fantastic, and very generally benign. Its best representative is unquestionably George Fox, the pious, gentle-hearted, humble-minded "man in leather breeches." Such wild visionaries as the Muggletonians, Fifth-monarchy men, and Ranters, of the English mystical period, were rather the offscourings of that much-suffering, much-endeavouring time, than the genuine representatives of British mysticism. The wisdom and folly, the greatness and littleness, the expansive benevolence and staid asceticism of George Fox are still partially to be met with in Quakerism, of which he was the father. (See FOX, and QUAKERISM.) In striking contrast with the rude fervour and doubtful prophesyings of the Society of Friends, and the other communities tainted with the mystical spirit during that time, was the mild Platonic mysticism, with its scholarly refinement and retiring devotion, of the English Platonists More, Norris, Gale, and Cudworth. Indeed, it is perhaps hardly just to denominate these men and their little school of wise, devout thinkers as mystics at all. They are never absurdly sentimental or foolishly extravagant: good sense generally pervades all their writings, and they abound in whatever is lofty in thought or tender in emotion. Yet a subtle vein of mysticism, like a silver thread, can be detected by the experienced eye running through their works; a peculiarity which it is impossible perhaps for a religious Platonist to avoid. (See under the name of each.)

Mysticism
of Sweden-
borg.

The theosophic mysticism of Emanuel Swedenborg stands alone among all the mystical systems which have yet been noticed. It is remarkable for its apparent reality and comprehensiveness, and, with the exception of the system of Behmen, it differs from that of all other mystics in three important respects. It strives constantly "to see the spiritual not beyond, but in the natural:" the flesh is no longer evil; and the world ceases to be the birthright of the devil. Hence its hostility to asceticism. In his theology, again, Swedenborg maintained a constant equilibrium between the letter and spirit of Scripture. There is with

him no discarding of the letter, no fantastical interpretation, but a rigid adherence to the words of Scripture which is quite unparalleled. Nor, again, does he display any of the rambling theorizing and turbid vehemence peculiar to all theosophists, and Behmen among the rest. With the Swedish seer all is scientific precision and calm serenity; he utters himself always with clear collectedness, and you never find him in a hurry. In his doctrine concerning spiritual influence he is peculiarly temperate and by no means mystical, and if he errs concerning the work of Christ, it arises mainly from his repugnance to Calvinism. His theology is more closely allied to Behmen's than to that of any other writer; yet he expressly informs us that he never read the German theosophist. (See SWEDENBORG; also *E. Swedenborg, a Biography*, by J. G. Wilkinson.)

Nothing really new in the way of mysticism has been produced since the days of the northern seer. German rationalism and French encyclopædism found a protest raised against their exclusive negativeness by the advocates of faith and feeling in religion and philosophy, and by the romanticists in literature. In Germany, Hamann and Jacobi opposed faith to the logic of the sceptic; Schelling gave the romanticists a poetical philosophy; and Schleiermacher taught them to read the Bible in the light of the individual "Christian consciousness." Romanticism finds its best representative in Novalis (Friedrich von Hardenberg); and among the more celebrated of its adherents were F. Schlegel, A. Müller, Z. Werner, and Tieck. (For an able annunciation of the principles of the genuine romanticism, see Tieck's *Prince Zerbino*.) Unmistakeable traces of this tendency are also to be found in the writings of Carlyle and Emerson; and in religion, mysticism still shows itself in the disciples of Fox, Swedenborg, and Edward Irving.

There are perhaps few forms of erroneous human development that have rendered so great service both to religion and philosophy as the system of mysticism. In an age of languid spiritual life, of cold formalism, or of heartless hypocrisy, it has invariably come forth into the moral wilderness, like the Baptist, "eating locusts and wild honey," to expose pretension and insincerity, and preach repentance unto men. In philosophy, likewise, it has ever been found to emerge when an extreme rationalism or a debasing materialism threatened the foundations of faith, and heralded a reign of scepticism. Yet, so entirely relative and limited are the human faculties, that every attempt put forth by them to transcend the natural bounds of legitimate science or of intelligent experience, has hitherto led only to extravagance and folly. The spiritualist, who follows only what his instincts dictate, is as much in error as the rationalist, who believes only what he is capable of sciencing. The idea that there is a special faculty for the discernment of spiritual truth—an inner soul, independent of experience and knowledge—has doubtless, in the hands of many, been a prolific source of mysticism. It is observable in Hugo, Tauler, and the Spanish mystics, and finds countenance in the declared divorce between Reason and Understanding in certain systems of modern speculation. Once confine the ordinary faculties of judging to the outer court of the temple of Truth, and exclude them from the sacred fane of Intuition, and we at once find ourselves in a region of transcendentalism, where nothing is seen and everything is affirmed,—where common sense finds no footing, and mysticism reigns supreme. The boundaries of faith are not necessarily limited by the extent of experience; yet without that experience, and the solid basis of fact which it brings, faith would find itself without any horizon at all, and left entirely at the mercy of wild extravagance or wilful caprice.

(See, in particular, *Hours with the Mystics*, by R. A. Vaughan, 2 vols., 1856; also *Die Christliche Mystik*, by Dr L. Noack; and *Cours de l'Hist. de la Phil. Moderne*, and *Fragmens Phil.*, by V. Cousin.)

(J. D—S.)

Mysticism.

Mytens
||
Mythology

MYTENS, DANIEL, a Dutch painter, was born at the Hague towards the close of the sixteenth century. He formed his style on the principles of Rubens, and grew particularly excellent in inserting warmly-tinted landscapes in the backgrounds of his portraits. He is found at the court of James I. of England as early as 1618. On the accession of Charles I. in 1625, the office of court painter was conferred upon him, and he began to execute those

fine portraits still to be seen at Hampton Court. The rival of Vandyck in 1632 diminished his success, and induced him to return to his native land, after having caught that great master's graceful style of painting costumes. The last notice of Mytens represents him as painting the ceiling of the town-hall at the Hague in 1656. Daniel Mytens had a son of the same name, who was also a painter.

MYTHOLOGY.

Definition. Is a term compounded of two Greek words, and in its original import it signifies any kind of fabulous doctrine. In its more appropriated sense, it means those fabulous details concerning the objects of worship which were invented and propagated by men who lived in the early ages of the world, and by them transmitted to succeeding generations, either by written records or by oral tradition.

As the theology and mythology of the ancients are almost inseparably connected, it will be impossible for us to develop the latter, without often introducing some observations relating to the former. We must therefore entreat the indulgence of our readers, if upon many occasions we should hazard a few strictures on the names, characters, adventures, and functions of such Pagan divinities as may have furnished materials for those fabulous narrations which the nature of the subject may lead us to discuss.

Origin of
fable.

With respect to *fable*, it may be observed in general, that it is a creature of the human imagination, and derives its birth from that love of the marvellous which is in a manner congenial to the soul of man. The appearances of nature which every day occur, objects, actions, and events, which succeed each other by a kind of routine, are too familiar, too obvious and uninteresting, either to gratify curiosity or to excite admiration. On the other hand, when the most common phenomena in nature or life are new-modelled by the plastic power of a warm imagination; when they are diversified, compounded, embellished, or even arranged and moulded into forms which seldom or perhaps never occur in the ordinary course of things; novelty generates admiration, a passion always attended with delightful sensations. Here then we imagine we have discovered the very source of fiction and fable. They originated from that powerful propensity in our nature towards the new and surprising, animated by the delight with which the contemplation of them is generally attended.

Many circumstances contributed to extend and establish the empire of fable. The legislator laid hold on this bias of human nature, and of course employed fable and fiction as the most effectual means to civilize a rude, unpolished world. The philosopher, the theologian, the poet, the musician, each in his turn made use of this vehicle to convey his maxims and instructions to the savage tribes. They knew that *truth*, simple and unadorned, is not possessed of charms powerful enough to captivate the heart of man in his present corrupt and degenerate state. This consideration, which did indeed result from the character of their audience, naturally led them to employ fiction and allegory. From this was derived the allegorical taste of the ancients, and especially of the primary sages of the East.

Boldness of the oriental mythology. Though almost every nation on the face of the globe, however remote from the centre of population, however savage and averse from cultivation, has fabricated and adopted its own system of mythology, the orientals have distinguished themselves in a peculiar manner, by the

boldness, the inconsistency, and the extravagance of their mythology. The genial warmth of those happy climes, the fertility of the soil, which afforded every necessary, every conveniency, and often every luxury of life, without depressing their spirits by laborious exertions; the face of nature perpetually blooming around them, the skies smiling with uninterrupted serenity; all contributed to inspire the orientals with a glow of fancy and a vigour of imagination rarely to be met with in less happy regions. Hence every object was swelled beyond its natural dimensions. Nothing was great or little in moderation, but every sentiment was heightened with incredible hyperbole. The magnificent, the sublime, the vast, the enormous, the marvellous, first sprung up, and were brought to maturity, in those native regions of fable and fairy land. As nature in the ordinary course of her operations, exhibited neither objects nor effects adequate to the extent of their romantic imaginations, they naturally deviated into the fields of fiction and fable. Of consequence, the custom of detailing fabulous adventures originated in the East, and was from thence transplanted into the western countries.

As the allegorical taste of the eastern nations had sprung from their propensity to fable, and as that propensity had in its turn originated from the love of the marvellous, so did allegory in process of time contribute its influence towards multiplying fables and fiction almost *in infinitum*. The latent import of the allegorical doctrines being in a few ages lost and obliterated, what was originally a moral or theological tenet assumed the air and habit of a personal adventure.

The propensity towards personification, almost universal among the orientals, was another fruitful source of fable to personification and allegory. That the people of the East were strongly inclined to personify inanimate objects and abstract ideas, we imagine will be readily granted, when it is considered, that in the formation of language they have generally annexed the affection of sex to those objects. Hence the distinction of grammatical genders, which is known to have originated in the eastern parts of the world. The practice of personifying virtues, vices, religious and moral affections, was necessary to support that allegorical style which universally prevailed in those countries. This mode of writing was in high reputation even in Europe some centuries ago; and to it we are indebted for some of the most noble poetical compositions now extant in our own language. Those productions, however, are but faint imitations of the original mode of writing still current among the eastern nations. The Europeans derived this species of composition from the Moorish inhabitants of Spain, who imported it from Arabia, their original country.

The general use of hieroglyphics in the East must have contributed largely towards extending the empire of mythology. As the import of the figures employed in this method of delineating the signs of ideas was in a great measure arbitrary, mistakes must have frequently been committed in ascertaining the notions which they were at

Mythology.

the first intended to represent.¹ When the development of these arbitrary signs happened to be attended with uncommon difficulty, the expounders were obliged to have recourse to conjecture. Those conjectural expositions were for the most part tinctured with that bias towards the marvellous which universally prevailed amongst the primitive men. This, we find, is the case even at this day, when moderns attempt to develop the purport of emblematical figures preserved on ancient medals, entaglios, and the like.

The wise men of the East delighted in obscure enigmatical sentences. They seem to have disdained every sentiment obvious to vulgar apprehension. The words of the wise, and their dark sayings, often occur in the most ancient records, both sacred and profane. The sages of antiquity used to vie with each other for the prize of superior wisdom, by propounding riddles, and dark and mysterious questions, as subjects of investigation. The contest between Solomon and Hiram, and that between Amasis king of Egypt and Polycrates tyrant of Samos, are universally known. As the import of those enigmatical propositions was often absolutely lost, in ages when the art of writing was little known, and still less practised, nothing remained but fancy and conjecture, which always verged towards the regions of fable. This, then, we think, was another source of mythology.

Mythology reduced to a kind of system in Egypt.

The Pagan priests, especially in Egypt, were probably the first who reduced mythology to a kind of system. The sacerdotal tribe, amongst that people, were the grand depositories of learning as well as of religion. That order of men monopolized all the arts and sciences. They seem to have formed a conspiracy among themselves, to preclude the laity from all the avenues of intellectual improvement. This plan was adopted with a view to keep the laity in subjection, and to enhance their own importance. To accomplish this end, they contrived to perform all the ministrations of their religion in an unknown tongue, and to cover them with a thick veil of fable and allegory. The language of Ethiopia became their sacred dialect, and hieroglyphics their sacred character.² Egypt, of course, became a kind of fairy land, where all was jugglery, magic, and enchantment. The initiated alone were admitted to the knowledge of the occult mystical exhibitions, which, in their hands, constituted the essence of their religion. From these the vulgar and profane were prohibited by the most rigorous penalties. (See MYSTERIES.) The Egyptians, and indeed all the ancients without exception, deemed the mysteries of religion too sacred and solemn to be communicated to the herd of mankind, naked and unreserved; a mode by which they imagined those sacred and sublime oracles would have been defiled and degraded. "Procul, O procul este profani:" "Odi profanum vulgus et arceo." Egypt was the land of graven images; allegory and mythology were the veil which concealed religion from the eyes of the vulgar; and fable was the groundwork of that impenetrable covering.

In the earliest ages of the world, in the earliest and most unpolished stage of society we cannot suppose fable to have existed amongst men. Fables are always *tales of other times*, but at this period other times did not reach far enough backward to afford those fruits of the imagination sufficient time to arrive at maturity.

Mythology.

Fable requires a considerable space of time to acquire credibility, and to rise into reputation. Accordingly, we find that both the Chinese and Egyptians, the two most ancient nations whose annals have reached our times, were altogether unacquainted with fabulous details in the most early and least improved periods of their respective monarchies. It has been shown almost to a demonstration, by a variety of learned men, that both the one and the other people, during some centuries after the general deluge, retained and practised the primitive Noachic religion, in which fable and fancy could find no place; all was genuine unsophisticated truth.

As soon as the authentic tradition concerning the origin of the universe was either in a good measure lost, or at least adulterated by the invention of men, fable and fiction began to prevail. The Egyptian Thoth, Thyoth, or Mercury Trismegistus, and Moschus the Phœnician, undertook to account for the formation and arrangement of the universe, upon principles purely mechanical. Here fable began to usurp the place of genuine historical truth. Accordingly, we find that all the historians of antiquity who have undertaken to give a general detail of the affairs of the world, have ushered in their narration with a fabulous cosmogony. Here imagination ranged unconfinèd over the boundless extent of the primary chaos. To be convinced of the truth of this assertion, we need only look into Sanchoniathon's Cosmogony, Eusebius (*Præp. Evang.* l. 1), and Diodorus Siculus. From this we suppose it will follow, that the first race of fables owed their birth to the erroneous opinions of the formation of the universe.

Having now endeavoured to point out the origin of mythology, or fabulous traditions, we shall proceed to lay before our readers a brief detail of the mythology of the most respectable nations of antiquity, following the natural order of their situation.

The Chinese, if any credit be due to their own annals, Chinese or to the missionaries of the church of Rome, who pretend to have copied from them, were the first of the nations. Their fabulous records reach upwards many myriads of years before the Mosaic era of the creation. The events during that period of time, if any had been recorded, must have been fabulous as the period itself. These, however, are buried in eternal oblivion. The missionaries, who are the only sources of our information with relation to the earliest periods of the Chinese history, represent those people as having retained the religion of Noah many centuries after the foundation of their empire. Upon this supposition, their cosmogony must have been sound and genuine, without the least tincture of those fabulous ingredients which have both disguised and disgraced the cosmogonies of most other nations.

According to the most authentic accounts, Fohe or Fohi laid the foundation of that empire about four thousand years ago. This emperor, according to the Chinese, was conceived in a miraculous manner. His mother, say they, one day as she was walking in a desert place, was surrounded by a rainbow; and, being impregnated by this meteor, was in due time delivered of that celebrated legislator. This personage, like the Athenian Cecrops, was half a man

¹ This, though plausible enough as a mere supposition or hypothesis, must be taken with more than grains of allowance, seeing it proceeds upon an assumption which is by no means correct in point of fact. It is not true that the *import* of the figures employed in the hieroglyphic delineation of ideas was "in a great measure arbitrary;" for, if this had been the case, then the interpretation of such figures would have been, in the same measure or proportion, impossible. Originally, no doubt, arbitrary values may have been affixed to certain figures or symbols, that is, values not depending on any obvious analogy or principle; but these being *once* conventionally settled, remained *invariable*, and were ever afterwards employed in an uniform sense or acceptation, as much so indeed as if they had been originally *natural* instead of *conventional* signs, expressive of certain ideas. This distinction should never be lost sight of in any observations on hieroglyphical writing, which, in truth, was but ill understood at the period when the above article was composed by its able and ingenious author. If constructed on any other principle than that now stated, it would have been altogether unintelligible. — Editor.

² The modern doctrine on this subject may be ascertained by consulting the article HIEROGLYPHICS.

Mythology.

and half a serpent. His intellectual powers were truly hyperbolic. In one day he discovered fifty different species of poisonous herbs. He taught his countrymen the whole art of agriculture in the space of a very few years. He instructed them how to sow five different sorts of grain. He invented boats, and nets for fishing, the art of fabricating porcelain, the management of silk-worms, the manufacturing of silk, &c. In a word, that wonderful personage was inspired by Heaven with knowledge, which qualified him for composing that incomparable body of laws which are even at this day the wonder of the world. Our readers will admit, that this whole detail is fabulous and chimerical. The most learned part of them will readily observe, that the Chinese, in ascribing the invention of all the useful arts to their Fohi, are perfectly agreed with almost all the other nations of antiquity. The Indians ascribe every invention to Budha, or Vishnu, or Foe; the Persians to Zerdusht or Zoroaster; the Chaldeans to their man of the sea, whom they call Oannes; the Egyptians to Thoth or Thyoth; the Phœnicians to Melicerta; the Greeks to the family of the Titans; and the Scandinavians to Odin.

Miraculous birth of Confucius.

About 551 years before the Christian era, appeared the famous Chinese philosopher *Con-fu-tse* or Confucius. Concerning the birth of this prince of philosophers, the Chinese have propagated the following legendary tale. His mother, walking in a solitary place, was impregnated by the vivifying influence of the heavens. The babe, thus produced, spake and reasoned as soon as it was born. Confucius, however, wrought no miracles, performed no romantic exploits, but lived an austere ascetic life, taught and inculcated the doctrines of pure morality, and died, remarkable only for superior wisdom, religious, moral, and political.

Lao-kiun and his doctrines.

About the year of Christ 601, flourished the sectary *Lao-kiun*. His mother carried him thirty years in her womb, and was at last delivered of him under a plum-tree. This philosopher was the Epicurus of the Chinese. His disciples, who were denominated the *Fao-sse*, that is, heavenly doctors, were the first who corrupted the religion of the Chinese. They were addicted to magic, and introduced the worship of good and bad demons. Their doctrine was embraced by a long succession of emperors. One of these princes, called *You-ti*, had been deprived by death of a favourite mistress, whom he loved with the most extravagant passion. The emperor, by the magical skill of one of these doctors, obtained an interview with his deceased mistress, a circumstance which riveted the whole order in the affection and esteem of the deluded prince. Here our readers will observe the exact counterpart of the fable of Eurydice, so famous in the mythology of the Greeks and Romans. That such a system of religious principles must have abounded with mythological adventures is highly probable; but as the missionaries, to whom we are chiefly indebted for our information relating to the religion of the Chinese, have not taken the pains to record them, we find it impossible to gratify the curiosity of our readers on that head.

Introduction of the worship of Fo.

The worship of the idol Fo, or Foe, was transplanted from India into China about the fifty-sixth year of the Christian era, upon the following occasion. One of the doctors of the *Fao-sse* had promised a prince of the family of Tchou, and brother of the Emperor Ming-ti, to make him enter into communion with the spirits. At his solicitation an ambassador was despatched into India, in order to inquire where the true religion was to be found. There had been a tradition, say the missionaries, ever since the age of Confucius, that the true religion was to be found in the West. The ambassador stopt short in India; and finding that the god Fo was in high reputation in that country, he collected several images of that deity painted on chintz, and with it forty-two chapters of the canonical

Mythology.

books of the Hindus, which, together with the images, he laid on a white elephant, and transported into his native country. At the same time he imported from the same quarter the doctrine of the transmigration of souls, which is firmly believed in China to this day. The doctrine and worship of Fo, thus introduced, made a most rapid progress all over China, Japan, Siam, &c. The priests of Fo are called amongst the Siamese *Talapoins*; by the Tartars, *Lamas*; by the Chinese, *Ha-chang*; and by the people of Japan, *Bonzes*. By this last appellation they are generally known in Europe.

An infinitude of fables was invented and propagated by the disciples of Fo, concerning the life and adventures of their master. If the earlier ages of the Chinese history are barren of mythological incidents, the later periods, after the introduction of the worship of Fo, furnish an inexhaustible store of miracles, monsters, fables, intrigue, exploits, and adventures, of the most villanous complexion. Indeed, most of them are so absurd, so ridiculous, and at the same time so impious and profane, that we are convinced our readers will easily dispense with a detail from which they could reap neither entertainment nor instruction. Such as may find themselves disposed to rake into this abominable puddle, we must refer to the reverend fathers Du Halde, Couplet, Amiot, Kircher, and other members of the propaganda, in whose writings they will find wherewithal to satisfy, and even to surfeit, their appetite.

The Hindus, like the other nations of the East, for a long time retained the worship of the true God. At length, however, idolatry broke in, and, like an impetuous torrent, overwhelmed the country. First of all, the genuine history of the origin of the universe was either utterly lost, or disguised under a variety of fictions and allegories. We are told that *Brahma*, the supreme divinity of the Hindus, after three several efforts, at last succeeded in creating four persons, whom he appointed to rule over all the inferior creatures. Afterwards Brahma joined his efficient power with Bishon and Rudra, and by their united exertions they produced ten men, whose general appellation is *Munies*, that is, the inspired. The same being, according to another mythology, produced four other persons, as imaginary as the former; one from his breast, one from his back, one from his lip, and one from his heart. These children were denominated *Bangs*, the import of which word we cannot pretend to determine. According to another tradition, Brahma produced the Brahmins from his mouth, to pray, to read, to instruct; the Chiltern from his arms, to draw the bow, to fight, to govern; the Bice from his belly or thighs, to nourish, to provide the necessaries of life by agriculture and commerce; the Soder from his feet, for subjection, to serve, to labour, to travel. The reader will see at once, in these allegorical persons, the four castes or sects into which the Hindu nations have, from time immemorial, been divided. These are some of their most celebrated mythological traditions with relation to the origin of the universe.

The Hindus have likewise some mythological opinions which seem to relate to the general deluge. They tell us, that desiring the preservation of herds and of brahmans, of genii and of virtuous men, of *vedas* of law, and of precious things, the lord of the universe assumes many bodily shapes; but though he pervades, like the air, a variety of beings, yet he is himself unvaried, since he has no quality in him subject to change. At the close of the last *calpa*, there was a general destruction, occasioned by the sleep of Brahm, whence his creatures in different worlds were drowned in a vast ocean. Brahm being inclined to slumber after a lapse of so many ages, the strong demon *Hyagri-va* came near him, and stole the *vedas* which had flowed from his lips. When *Heri*, the preserver of the universe, discovered this deed of the prince of *Dainavas*, he

Hindu traditions relating to the deluge.

Mythology.

took the shape of a minute fish called *Sap-hari*. After various transformations, and an enormous increase of size in each of them, the lord of the universe, loving the righteous man,¹ who had still adhered to him under all these various shapes, and, intending to preserve him from the sea of destruction caused by the depravity of the age, thus told him how he was to act: "In seven days from the present time, O thou tamer of enemies, the three worlds will be plunged in an ocean of death; but in the midst of the destroying waves a large vessel sent me for thy use shall stand before thee." The remaining part of the mythology so nearly resembles the Mosaic history of Noah and the general deluge, that the former may be a strong confirmation of the truth of the latter. To dry up the waters of the deluge, the power of the Deity descends in the form of a boar, the symbol of strength, to draw up and support on his tusks the whole earth, which had been sunk beneath the ocean. Again, the same power is represented as a tortoise sustaining the globe, which had been convulsed by the violent assaults of demons, while the gods charmed the sea with the mountain *Mandar*, and forced it to disgorge the sacred things and animals, together with the water of life, which it had swallowed. All these stories, we think, relate to the same event, shadowed by a moral, a metaphysical and an astronomical allegory; and all three seem connected with the hieroglyphical sculptures of the old Egyptians.

The Hindus divide the duration of the world into four *yugs* or *jugs*, or *jogues*, each consisting of a prodigious number of years. In each of those periods the age and stature of the human race have been gradually diminished; and in each of them mankind has gradually declined in virtue and piety, as well as in age and stature. The present period they call the *collæ*, that is, the corrupt yug, which they say is to last four hundred thousand years, of which near five thousand years are already past. In the last part of the preceding yugs, which they call the *dwa paar*, the age of man was contracted into a thousand years, as in the present it is confined to a hundred. From this proportional diminution of the length of human life, our readers will probably infer, that the two last yugs bear a pretty near resemblance to the Mosaic history of the age of the antediluvian and postdiluvian patriarchs; and that the two first are imaginary periods prior to the creation of the world, like those of the Chinese, Chaldeans, and Egyptians.

The world subject to various dissolutions and resuscitations.

According to the mythology of the Hindus, the system of the world is subject to various dissolutions and resuscitations. At the conclusion of the *collæ* jogue, say they, a grand revolution will take place, when the solar system will be consumed by fire, and all the elements reduced to their original constituent atoms. Upon the back of these revolutions, Brahma, the supreme deity of the Hindus, is sometimes represented as a new-born infant, with his toe in his mouth, floating on a camala or water flower, sometimes only on a leaf of that plant, on the surface of the vast abyss. At other times he is figured as coming forth of a winding shell, and again as blowing up the mundane foam with a pipe at his mouth. Some of these emblematical figures and attitudes, our learned readers will probably observe, nearly resemble those of the ancient Egyptians.

Birth of the god Fo.

But the vulgar religion of the ancient Hindus was of a very different complexion, and opens a large field of mythological adventures. We have observed above, that the Fo or Foh of the Chinese was imported from India; and now we shall give a brief detail of the mythological origin of that divinity. We have no certain account of the birth-place of this imaginary deity. His followers relate that

he was born in one of the kingdoms of India near the line, and that his father was one of that country. His mother brought him into the world by the left side, and expired soon after her delivery. At the time of her conception, she dreamed that she had swallowed a white elephant; a circumstance which is supposed to have given birth to the veneration which the kings of India have always shown for a white animal of that species. As soon as he was born, he had strength enough to stand erect without assistance. He walked abroad at seven, and, pointing with one hand to the heavens, and with the other to the earth, he cried out, "In the heavens, and on the earth, there is no one but I who deserves to be honoured." At the age of thirty, he felt himself all on a sudden filled with the divinity; and now he was metamorphosed into Fo or Pagod, according to the expression of the Hindus. He had no sooner declared himself a divinity, than he thought of propagating his doctrine, and proving his divine mission by miracles. The number of his disciples was immense; and they soon spread his dogmas over all India, and even to the higher extremities of Asia.

Mythology.

One of the principal doctrines which Fo and his disciples propagated, was the metempsychosis or transmigration of souls. This doctrine, some imagine, has given rise to the multitude of idols revered in every country where the worship of Fo is established. Quadrupeds, birds, reptiles, and the vilest animals, had temples erected for them; because, say they, the soul of the god, in his numerous transmigrations, may have at one time or other inhabited their bodies.

Both the doctrine of transmigration and of the worship of animals seems, however, to have been imported from Egypt into India. If the intercourse between these two countries was begun at so early a period as some very late writers have endeavoured to prove, such a supposition is by no means improbable. The doctrine of the transmigration of souls was early established among the Egyptians. It was, indeed, the only idea they formed of the soul's immortality. The worship of animals among them seems to have been still more ancient. If such an intercourse did actually exist, we may naturally suppose that colonies of Egyptian priests found their way into India, as they did afterwards into Asia Minor, Italy, and Greece. That colonies of Egyptians did actually penetrate into that country, and settle there, many centuries before the Nativity, is a fact that cannot be called in question, for reasons which the bounds prescribed us in this article will not allow us to enumerate. We shall only observe, that from the hieroglyphical representations of the Egyptian deities seem to have originated those monstrous idols which from time immemorial have been worshipped in India, China, Japan, Siam, and even in the remotest parts of Asiatic Tартary.

Foh is often called *Budha* or *Budda*, and sometimes *Vishnu*. The incarnations of Vishnu. Perhaps, indeed, he may be distinguished by many names, according to the variety of dialects of the different nations among which his worship was established. An infinitude of fables was propagated by his disciples concerning him after his death. They pretended that their master was still alive; that he had been already born eight thousand times, and that he had successively appeared under the figure of an ape, a lion, a dragon, an elephant, a boar, &c. These were called the incarnations of Vishnu. At length he was confounded with the Supreme God; and all the titles, attributes, operations, perfections, and ensigns of the Most High were ascribed to him. Sometimes he is called Amida, and represented with the head of a dog, and worshipped as the guardian of mankind. He sometimes appears as a princely personage, issuing from the

¹ He was sovereign of the world. His name was *Manu*, or Statgavrata; and his patronymic was *Vaisvata*, or Child of the Sun

Mythology.

mouth of a fish. At other times, he wears a lunette on his head, in which are seen cities, mountains, towers, trees, in short, all that the world contains. These transformations are evidently the children of allegorical or hieroglyphical emblems, and form an exact counterpart of the symbolical worship of the Egyptians.

The enormous mass of mythological traditions which have in a manner deluged the vast continent of India would fill many volumes. We have selected the preceding articles as a specimen only, by which our readers may be qualified to judge of the rest. If they find themselves disposed to indulge their curiosity at greater length, we must refer them to Thevenot's and Hamilton's Travels, to M. Anquetil in his *Zendavesta*, Halhed's Introduction to his translation of the code of Gentoo Laws, Colonel Dow's History of Hindustan, Gröse's Voyage to the East Indies, and the Asiatic Researches (vol. i. and ii.).

Persian mythology.

The mythology of the Persians is, if possible, still more extravagant than that of the Hindus. It supposes the world to have been repeatedly destroyed, and repopulated by creatures of different formation, who were successively annihilated or banished for their disobedience to the Supreme Being. The monstrous griffin *Sinergh* informs the hero *Caherman* that she had already lived to see the earth seven times filled with creatures, and seven times a perfect void; that before the creation of Adam, this globe was inhabited by a race of beings called *Peris* and *Dives*, whose characters formed a perfect contrast. The *Peris* are described as beautiful and benevolent; the *Dives* as deformed, malevolent, and mischievous, differing from infernal demons only in this, that they are not as yet confined to the pit of hell. They are for ever ranging over the world, to scatter discord and misery amongst the sons of men. The *Peris* nearly resemble the fairies of Europe; and perhaps the *Dives* gave birth to the giants and magicians of the middle ages. The *Peris* and *Dives* wage incessant wars; and when the *Dives* make any of the *Peris* prisoners, they shut them up in iron cages, and hang them on the highest trees, to expose them to public view, and to the fury of every chilling blast.

When the *Peris* are in danger of being overpowered by their foes, they solicit the assistance of some mortal hero, which produces a series of mythological adventures highly ornamental to the strains of the Persian bards, and which at the same time furnishes an inexhaustible fund of the most diversified machinery.

One of the most celebrated adventurers in the mythology of Persia is *Tahmuras*, one of their most ancient monarchs. This prince performs a variety of exploits while he endeavours to recover the fairy Merjan. He attacks the Dive Demrush in his own cave, where, having vanquished the giant or demon, he finds vast piles of hoarded wealth, which he carries off with the fair captive. The battles, labours, and adventures of Rostan, another Persian worthy, who lived many ages after the former, are celebrated by the Persian bards with the same extravagance of hyperbole with which the labours of Hercules have been sung by the poets of Greece and Rome.

Persia the birth-place of chivalry and romance.

The adventures of the Persian heroes breathe all the wildness of achievement recorded of the knights of Gothic romance. The doctrine of enchantments, transformations, and the like, exhibited in both, is a characteristic symptom of one common original. Persia is the genuine classic ground of eastern mythology, and the source of the ideas of chivalry and romance, which were thence propagated to the regions of Scandinavia, and indeed to the remotest corners of Europe towards the west.

Perhaps our readers may be inclined to adopt our opinion, when we offer it as a conjecture, that the tales of the war of the *Peris* and *Dives* originated from a vague tradition concerning good and bad angels. Nor is it, we think,

Mythology.

at all improbable, that the fable of the wars between the gods and giants, so famous in the mythology of Greece and Italy, was imported into the former of these countries from the same quarter. (For a more particular account of the Persian mythology, our readers may consult Dr Hyde, *Relig. Vet. Pers.*; D'Herbelot's *Bibl. Orient.*; and Richardson's Introduction to his Persian and Arabic Dictionary.)

The mythology of the Chaldeans, like that of the other Chaldean nations of the East, commences at a period myriads of years prior to the era of the Mosaic creation. Their cosmogony, exhibited by Berosus, who was a priest of Belus, and deeply versed in the antiquities of his country, is a piece of mythology of the most extravagant nature. It has been copied by Eusebius (*Chron.* lib. i. p. 5); and it is likewise to be found in Syncellus, copied from Alexander Polyhistor. According to this historian, there were at Babylon written records preserved with the greatest care, comprehending a period of fifteen myriads of years. Those writings likewise contained a history of the heavens and the sea, of the earth, and of the origin of mankind. "In the beginning," says Berosus, copying from Oannes, of whom we shall afterwards give a brief account, "there was nothing but darkness and an abyss of water, wherein resided most hideous beings produced from a twofold principle. Men appeared with two wings; some with two and some with four faces. They had one body, but two heads; the one of a man, the other of a woman. Other human figures were to be seen, furnished with the legs and horns of goats. Some had the feet of horses behind, but before were fashioned like men, resembling hippocentaurs." The remaining part of this mythology is much of the same complexion; indeed so extravagant, that we imagine our readers will readily enough dispense with our translating the sequel. "Of all these," says the author, "were preserved delineations in the temple of Belus at Babylon. The person who was supposed to preside over them was called *Omorea*. This word, in the Chaldean language, is *Thalath*, which the Greeks call *Θαλασσα*, but it more properly imports the moon. Matters being in this situation, their god, says Eusebius, the god, says Syncellus, came and cut the woman asunder; and out of one half of her he formed the earth, and out of the other he made the heavens; and, at the same time, he destroyed the monsters of the abyss." This whole mythology is an allegorical history copied from hieroglyphical representations, the real purport of which could not be deciphered by the author. Such, in general, were the consequences of the hieroglyphical style of writing.

Oannes, the great civilizer and legislator of the Chaldeans, according to Apollodorus, who copied from Berosus, was an amphibious animal of a heterogeneous appearance. He was endowed with reason, and a very uncommon acuteness of parts. His whole body resembled a fish. Under the head of a fish he had also another head, and feet below similar to those of a man, which were subjoined to the tail of the fish. His voice and language were articulate, and perfectly intelligible; and there was a figure of him still extant in the days of Berosus. He made his appearance in the Erythrean or Red Sea, where it borders upon Babylonia. This monstrous being conversed with men by day; but at night he plunged into the sea, and remained concealed in the water till next morning. He taught the Babylonians the use of letters, and the knowledge of all the arts and sciences. He instructed them in the method of building houses, constructing temples, and all other edifices. He taught them to compile laws and religious ceremonies, and explained to them the principles of mathematics, geometry, and astronomy. In a word, he communicated to them every thing necessary, useful, and ornamental; and so universal were his instructions, that not

Mythology.

one single article had ever been added to them since the time they were first communicated. Helladius is of opinion that this strange personage, whoever he was, came to be represented under the figure of a fish, not because he was actually believed to be such, but because he was clothed with the skin of a seal. By this account our readers will see that the Babylonian Oannes is the exact counterpart of the Fohi of the Chinese, and the Thoth or Mercury Trismegistus of the Egyptians. It is likewise apparent that the idea of the monster compounded of the man and the fish has originated from some hieroglyphic emblem of that form grafted upon the appearance of man. Some modern mythologists have been of opinion that Oannes was actually Noah, the great preacher of righteousness, who, as some think, settled in Shinar or Chaldaea after the deluge, and who, in consequence of his connection with that event, might be properly represented under the emblem of the Man of the Sea.

The nativity of the goddess of beauty and love.

The nativity of Venus, the goddess of beauty and love, is another piece of mythology famous amongst the Babylonians and Assyrians. An egg, say they, of a prodigious size, dropped from heaven into the river Euphrates. Some doves settled upon this egg, after the fishes had rolled it to the bank. In a short time this egg produced Venus, who was afterwards called *Dea Syria*, or the Syrian goddess. In consequence of this tradition, says Hyginus, pigeons and fishes became sacred to this goddess amongst the Syrians, who always abstained from eating the one or the other. Of this imaginary being we have a very exact and entertaining history in the treatise *De Dea Syria*, generally ascribed to Lucian.

In this mythological tradition our readers will probably discover an allusion to the celebrated Mundane Egg; and at the same time the story of the fishes will lead them to anticipate the connection between the sea and the moon. This same deity was the Atargatis of Ascalon, described by Diodorus the Sicilian; the one half of her body being that of a woman, and the other that of a fish. This was no doubt a hieroglyphic figure of the moon, importing the influence of that planet upon the sea and the sex. The oriental name of this deity evidently points to the moon; for it is compounded of two Hebrew words,¹ importing "the queen of the host of heaven."

The fable of Semiramis.

The fable of Semiramis is nearly connected with the preceding one. Diodorus Siculus has preserved the mythological history of this deity, which he and all the writers of antiquity have confounded with the Babylonian princess of the same name. That historian informs us, that the word *Semiramis*, in the Syrian dialect, signifies "a wild pigeon;" but we apprehend that this term was a name or epithet of the moon, as it is compounded of two words² of an import naturally applicable to the lunar planet. It was a general practice amongst the Orientals to denominate their sacred animals from that deity to which they were consecrated. Hence the moon being called *Semiramis*, and the pigeon being sacred to her divinity, the latter was called by the name of the former.³

Arabian mythology.

We should now proceed to notice the mythology of the Arabians, the greater part of which is, however, buried in the abyss of ages; although, when we reflect on the genius and character of that people, we must be convinced that they too, as well as the other nations of the East, abounded in fabulous relations and romantic compositions. The natives of that country have always been enthusiasti-

cally addicted to poetry, of which, in its early stage, fable is the essence. Wherever the Muses have erected their throne, fables and miracles have always appeared in their train. In the Koran we meet with frequent allusions to well-known traditionary fables. These had been transmitted from generation to generation by the bards and rhapsodists, for the entertainment of the vulgar. In Arabia, from the earliest ages, it has always been one of the favourite entertainments of the common people, to assemble in the serene evenings around their tents, or on the platforms with which their houses are generally covered, or in large halls erected for the purpose, in order to amuse themselves with traditional narrations of the most distinguished actions of their most remote ancestors. Oriental imagery always embellished their romantic details. The glow of fancy, the love of the marvellous, the propensity towards the hyperbolic and the vast, which constitute the essence of oriental description, must ever have drawn the relation aside into the devious regions of fiction and fairy land. The religion of Mahommed beat down the original fabric of idolatry and mythology together. The Arabian fables current in modern times are borrowed or imitated from Persian compositions; Persia being still the grand nursery of romance in the East.

Mythology.

In Egypt we find idolatry, theology, and mythology, Egyptian almost inseparably blended together. The inhabitants of this region, too, as well as of others in the vicinity of the centre of population, adhered for several centuries to the worship of the true God. At last, however, conscious of their own ignorance, impurity, imperfection, and total unfitness to approach an infinitely perfect Being, distant, as they imagined, and invisible, they began to cast about for some beings more exalted, and more perfect than themselves, by whose mediation they might prefer their prayers to the Supreme Majesty of heaven. In this state, the luminaries of heaven, which, they imagined, were animated bodies, naturally presented themselves. These were splendid and glorious beings. They were thought to partake of the divine nature; they were revered as the satraps, prefects, and representatives of the Supreme Lord of the universe. They were visible, they were beneficent; they dwelt nearer to the gods; they were obvious to the worshipper, and always accessible. These were, of course, employed as mediators and intercessors between the Supreme Divinity and his humble subjects of this lower world. Thus employed, they might claim a subordinate share of worship, which was accordingly assigned them. In process of time, however, that worship, which was originally addressed to the Supreme Creator by the mediation of the heavenly bodies, was in a great measure forgotten, and the adoration of mankind ultimately terminated upon those illustrious creatures. To this circumstance, we think, we may ascribe the origin of that species of idolatry called Tsabaism, or the worship of the host of heaven, which overspread the world early and almost universally. In Egypt this mode of worship was adopted in all its most absurd and most enthusiastic forms, and at the same time the most heterogeneous mythology appeared in its train. The mythology of the ancient Egyptians was so various and multifarious, so complicated and so mysterious, that it would require many volumes even to give a superficial account of its origin and progress, not only in its mother country, but even in many other parts of the eastern and western world. Besides, the idolatry and mythology of that wonderful

¹ ADAR or HADAR, *magnificus*, and GAD, *exercitus, turma*.

² *Shem* or *Sem*, a sign, and *ramah*, high.

³ As the bounds prescribed for the present article render it impossible for us to do justice to this interesting piece of mythology, we must beg leave to refer our readers for farther information to Diodorus Siculus, lib. ii.; Hyginus, *Poet. Astron. Fab.* 197; Pharnutus, *de Nat. Deor.*; Ovid, *Metam.* lib. iv.; Athen. in *Apol.*; Tzetzes, chil. ix. cap. 275; Selden, *de Diis Syr.* ii. 183.

Mythology.

country are so closely connected and so inseparably blended together, that it is impossible to describe the latter without at the same time developing the former. We hope, therefore, that our readers will not be disappointed, if, in an article of this nature, we touch only upon some of the leading or most interesting articles of this complicated subject.

Reign of gods and demigods in Egypt.

The Egyptians confounded the revolutions of the heavenly bodies with the reigns of their most early monarchs. Hence the incredible number of years included in the reign of their eight superior gods, who, according to them, filled the Egyptian throne successively in the most early periods of time. To these, according to their system, succeeded twelve demigods, who likewise reigned an amazing number of years. These imaginary reigns were no other than the periodical revolutions of the heavenly bodies preserved in their almanacs, which might be carried back, and actually were carried back, at pleasure. Hence the fabulous antiquity of that kingdom. The imaginary exploits and adventures of these gods and demigods furnished an inexhaustible fund of mythological romances. To the demigods succeeded the kings of the cynic cycle, personages equally chimerical with the former. The import of this epithet has greatly perplexed critics and etymologists. We apprehend that it is an oriental word importing *royal* dignity, or elevation of rank. This appellation intimated, that the monarchs of that cycle, admitting that they actually existed, were more powerful and more highly revered than their successors. After the princes of the cynic cycle came another race, denominated *Nekyes*, a title likewise implying royal, splendid, glorious. These cycles figure high in the mythological annals of the Egyptians, and have furnished materials for a variety of learned and ingenious disquisitions. The wars and adventures of Osiris, Orus, Typhon, and other allegorical personages who figure in the Egyptian rubric; the wanderings of Isis, the sister and wife of Osiris; the transformation of the gods into divers kinds of animals; their birth, education, peregrinations, and exploits; compose a body of mythological fictions so various, so complicated, so ridiculous, and often so apparently absurd, that all attempts to develop and explain them have hitherto proved unsuccessful. All, or the greater part, of those extravagant fables, were the offspring of hieroglyphical or allegorical emblems devised by the priests and sages of that nation, with a view to conceal the mysteries of their religion from that class of men whom they stigmatized with the name of the uninitiated rabble.

Worship of brute animals.

The worship of brute animals and of certain vegetables, universal amongst the Egyptians, was another exuberant source of mythological adventures. The Egyptian priests, many of whom were likewise profound philosophers, observed, or pretended to observe, a kind of analogy between the qualities of certain animals and vegetables, and those of some of their subordinate divinities. Such animals and vegetables they adopted, and consecrated to the deities to whom they were supposed to bear this analogical resemblance; and in process of time they considered them as the visible emblems of those divinities to which they were consecrated. By these the vulgar addressed their archetypes, in the same manner as, in other countries, pictures and statues were employed for the very same purpose. The mob, in process of time, forgetting the emblematical character of those brutes and vegetables, addressed their

devotion immediately to them; and of course these became the ultimate objects of vulgar adoration.

After these objects, animate or inanimate, were consecrated as the visible symbols of the deities, it soon became fashionable to make use of their figures to represent those deities to which they were consecrated. This practice was the natural consequence of the hieroglyphical style which universally prevailed amongst the ancient Egyptians. Hence Jupiter Ammon was represented under the figure of a ram, Apis under that of a cow, Osiris of a bull, Pan of a goat, Thoth or Mercury of an ibis, Bubastis or Diana of a cat. It was likewise a common practice amongst those deluded people to dignify these objects, by giving them the names of those deities which they represented. By this mode of dignifying these sacred emblems, the veneration of the rabble was considerably enhanced, and the ardour of their devotion inflamed in proportion. From these two sources, we think, are derived the fabulous transformation of the gods, so generally celebrated in the Egyptian mythology, and from it imported into Greece and Italy. In consequence of this practice, their mythological system was rendered at once enormous and unintelligible.¹

Their Thoth, or Mercury Trismegistus, was, in our opinion, the inventor of this unhappy system. This personage, according to the Egyptians, was the original author of letters, geometry, astronomy, music, and architecture; in a word, of all the elegant and useful arts, and of all the branches of science and philosophy. He it was who first discovered the analogy between the divine affections, influences, appearances, operations, and the corresponding properties, qualities, and instincts of certain animals, and the propriety of dedicating particular kinds of vegetables to the service of particular deities. The priests, whose province it was to expound the mysteries of that allegorical hieroglyphical religion (see MYSTERIES), gradually lost all knowledge of the primary import of the symbolical characters. To supply this defect, and at the same time to veil their own ignorance, the sacerdotal instructors had recourse to fable and fiction. They heaped fable upon fable, till their religion became an accumulated chaos of mythological absurdities. Two of the most learned and most acute of the ancient philosophers have attempted a rational explication of the latent import of the Egyptian mythology; but both have failed in the attempt; nor have the moderns, who have laboured in the same department, performed their part with much better success.²

Mythology.

The elements of Phœnician mythology have been pre-Phœnician served by Eusebius (*Præparat. Evang.* sub init.). In the large extract which that learned father had copied from Philo Biblius's translation of Sanchoniathon's History of Phœnicia, we are furnished with several articles of mythology. Some of these throw considerable light on several passages of the sacred history; and all of them are strictly connected with the mythology of the Greeks and Romans. There we have preserved a brief but entertaining detail of the fabulous adventures of Uranus, Cronus, Dagon, Thyoth or Mercury, probably the same with the Egyptian hero of that name. Here we find Muth or Pluto, Hephæstus or Vulcan, Æsculapius, Nereus, Poseidon or Neptune, &c. Astarte, or Venus Urania, makes a conspicuous figure in the catalogue of Phœnician worthies; Pallas or Minerva is planted upon the territory of Attica; in a word, all the branches of the family of the Titans, who in after ages

¹ See, on this subject, Sir William Drummond's *Origines*, &c. b. iv. c. 5, vol. ii. p. 146.

² Instead, therefore, of prosecuting this inexplicable subject, which would swell the present article beyond all proportion, we must beg leave to refer those who are desirous of further information, to the following authors, where they will find enough to gratify their curiosity, if not to inform their judgment:—Herodotus, lib. ii.; Diodorus Siculus, lib. i.; Plutarch, *Isis et Osiris*; Jamblichus, *de Myst. Egypt.*; Horus Apollo, *Hieroglyph. Egypt.*; Macrobius, *Saturn.* cap. 23, amongst the ancients: and, amongst the moderns, Kircher's *Œdipus*; Vossius, *de Orig. et Prog. Idol.*; Mr Bryant's *Analysis of Anc. Mythol.*; Gebelin, *Monde Primitif*; and, above all, to the learned Jablonski's *Pantheon Egyptiorum*.

Mythology.

Grecian mythology derived from Egypt and Phœnicia.

figured in the rubric of the Greeks, are brought upon the stage, and their exploits and adventures briefly detailed.

By comparing this fragment with the mythology of the Atlantidæ and that of the Cretans preserved by Diodorus the Sicilian (lib. v.), we think there is good reason to conclude, that the family of the Titans, the several branches of which seem to have been both the authors and objects of a great part of the Grecian idolatry, originally emigrated from Phœnicia. This conjecture will receive additional strength, when it is considered that almost all their names recorded in the fabulous records of Greece may be easily traced up to a Phœnician original. We agree with Herodotus, that a considerable part of the idolatry of Greece may have been borrowed from the Egyptians; at the same time, we imagine it highly probable, that the idolatry of the Egyptians and Phœnicians was in its original constitution nearly the same. Both systems were Tsabaism, or the worship of the host of heaven. The Pelasgi, according to Herodotus, learned the names of the gods from the Egyptians; but in this conjecture he is certainly warped by his partiality for that people. Had those names been imported from Egypt, they would no doubt have bewrayed their Egyptian original; whereas the skilful etymologist will be convinced that every one is of Phœnician extraction.

The adventures of Jupiter, Juno, Mercury, Apollo, Diana, Mars, Minerva or Pallas, Venus, Bacchus, Ceres, Proserpine, Pluto, Neptune, and the other descendants and coadjutors of the ambitious family of the Titans, furnish by far the greatest part of the mythology of Greece. They left Phœnicia, we think, about the age of Moses; they settled in Crete, a large and fertile island; from this region they made their way into Greece, which, according to the most authentic accounts, was at that time inhabited by a race of savages. The arts and inventions which they communicated to the natives; the mysteries of religion which they inculcated; the laws, customs, polity, and good order which they established; in short, the blessings of humanity and civilization which they everywhere disseminated, in process of time inspired the unpolished inhabitants with a kind of divine admiration. Those ambitious mortals improved this admiration into divine homage and adoration. The greater part of that worship, which had been formerly addressed to the luminaries of heaven, was now transferred to those illustrious personages. They claimed and obtained divine honours from the deluded rabble of enthusiastic Greeks. Hence sprung an inexhaustible fund of the most inconsistent and irreconcilable fictions.

Hence the inconsistent fictions of the Greek poets.

The foibles and frailties of the deified mortals were transmitted to posterity, incorporated, as it were, with the pompous attributes of supreme divinity. Hence the heterogeneous mixture of the mighty and the mean which chequers the characters of the heroes of the Iliad and Odyssey. The Greeks adopted the oriental fables, the import of which they did not understand. These they accommodated to heroes and illustrious personages, who had figured in their own country in the earliest periods. The labours of Hercules originated in Egypt, and evidently relate to the annual progress of the sun in the zodiac, though the vain-glorious Greeks accommodated them to a hero of their own, the reputed son of Jupiter and Alcmena. The expedition of Osiris they borrowed from the Egyptians, and transferred to their Bacchus, the son of Jupiter and Semele the daughter of Cadmus. The transformation and wanderings of Io are evidently transcribed from the Egyptian romance of the travels of Isis in quest of the body of Osiris, or of the Phœnician Astarte, drawn from Sancho-niathon. Io or Ioh is in reality the Egyptian name of the moon, and Astarte was the name of the same planet amongst the Phœnicians. Both these fables are allegorical repre-

sentations of the anomalies of the lunar planet, or perhaps the progress of the worship of that planet in different parts of the world. The fable of the conflagration occasioned by Phaeton is clearly of oriental extraction, and alludes to an excessive drought which in the early periods of time scorched Ethiopia and the adjacent countries. The fabulous adventures of Perseus are said to have happened in the same regions, and are allegorical representations of the influence of the solar luminary; for the original Perseus was the sun. The rape of Proserpine and the wanderings of Ceres, the Eleusinian mysteries, the orgia or sacred rites of Bacchus, the rites and worship of the Cabiri, were imported from Egypt and Phœnicia, but strangely garbled and disfigured by the hierophants of Greece. The gigantomachia, or war between the gods and the giants; and all the fabulous events and varieties of that war, form an exact counterpart to the battles of the Peris and Dives, celebrated in the romantic annals of Persia.

A considerable part of the mythology of the Greeks The sprung from their ignorance of the oriental languages. ^{Greeks ignorant of oriental languages.} They disdained to apply themselves to the study of languages spoken by people whom, in the pride of their heart, they stigmatized with the epithet of *barbarians*. This aversion to every foreign dialect was highly detrimental to their progress in the sciences. The same neglect or aversion has, we imagine, proved an irreparable injury to the republic of letters in all succeeding ages. The aoids, or strolling bards, laid hold on those oriental legends, which they sophisticated with their own additions and improvements, in order to accommodate them to the popular taste. These wonderful tales figured in their rhapsodical compositions, and were greedily swallowed down by the credulous vulgar. Those fictions, as they rolled down, were constantly augmented with fresh materials, till in process of time their original import was either forgotten or buried in impenetrable darkness. A multitude of these Hesiod has collected in his *Theogonia*, or Generation of the Gods, which unhappily became the religious creed of the illiterate part of the Greeks. Indeed fable was so closely interwoven with the religion of that airy, volatile people, that it seems to have contaminated not only their religious and moral, but even their political tenets.

The far-famed oracle of Dodona was copied from that of Ammon at Thebes in Upper Egypt. The oracle of Apollo Dodona at Delphos was an emanation from the same source. The celebrated Apollo Pythius of the Greeks was no other than the Ob or Aub of the Egyptians, who denominated the basilisk or royal snake *Ov Cai*, because it was held sacred to the sun. Ob or Aub is still retained in the Coptic dialect, and is one of the many names or epithets of that luminary. In short, the groundwork of the Grecian mythology is to be traced in the East. Only a small part of it was fabricated in the country; and what was imported pure and genuine was miserably sophisticated by the hands through which it passed, in order to give it a Grecian air, and to accommodate its style to the Grecian taste. To enlarge upon this topic would be altogether superfluous, as our learned readers must be well acquainted with it already, and the unlearned may, without much trouble or expense, furnish themselves with books upon that subject.

The Roman mythology was borrowed from the Greeks. ^{Roman mythology borrowed from Greece.} That people had addicted themselves for many centuries to the arts of war and civil polity. Science and philosophy were either neglected or unknown. At last they conquered Greece, the native land of science, and then "*Græcia capta ferum victorem cepit et artes intulit agresti Latio.*" This being the case, their mythology was, upon the whole, a transcript from that of Greece. They had indeed gleaned a few fables from the Pelasgi and others, which, however, are of so little consequence, that they are scarcely worth the trouble of transcribing.

Mythology.

Mythology.

The mythology of the Celtic nations is in a great measure lost. There may possibly still remain some vestiges of the druidical superstition in the remotest parts of the Highlands and Islands of Scotland, and perhaps in the uncivilized places of Ireland. These, we presume, would afford our readers but little entertainment, and still less instruction.

Mythology of the northern nations.

The mythology of the northern nations, that is, of the Norwegians, Danes, Swedes, and Icelanders, is uncommonly curious and entertaining. The Edda and Voluspa contain a complete collection of fables which have not the smallest affinity with those of the Greeks and Romans. They are wholly of an oriental complexion, and seem almost congenial with the tales of the Persians above described. The Edda was compiled in Iceland in the thirteenth century. It is a kind of system of the Scandinavian mythology; and it has been reckoned, and we believe justly, a commentary on the Voluspa, which was the Bible of the northern nations. Odin or Othin, or Woden or Waden, was the supreme divinity of those people. His exploits and adventures furnish the far greater part of their mythological creed. That hero is supposed to have emigrated from the East, but from what country or at what period is not certainly known. His achievements are magnified beyond all credibility. He is represented as the god of battles, and as slaughtering thousands at a blow. His palace is called Valhalla; it is situated in the city of Midgard, where, according to the fable, the souls of heroes who had bravely fallen in battle enjoy supreme felicity. They spend the day in mimic hunting matches, or imaginary combats. At night they assemble in the palace of Valhalla, where they feast on the most delicious viands, dressed and served up by the Valkyriæ, virgins adorned with celestial charms, and flushed with the bloom of everlasting youth. They solace themselves with drinking mead out of the skulls of enemies whom they had killed in their days of nature. Mead, it seems, was the nectar of the Scandinavian heroes.

The hell and devil of the Scandinavians.

Sleepner, the horse of Odin, is celebrated along with his master. Hela, the hell of the Scandinavians, affords a variety of fables equally shocking and heterogeneous. Loke, the evil genius or devil of the northern people, nearly resembles the Typhon of the Egyptians. Signa or Sinna is the consort of Loke; and from this name the English word *sin* is derived. The giants Weymur, Ferbanter, Belupher, and Hellunda, perform a variety of exploits, and are exhibited in the most frightful attitudes. One would be tempted to imagine, that they perform the exact counterpart of the giants of the Greek and Roman mythologists. Instead of glancing at these ridiculous and uninteresting fables, which is all that the limits prescribed us would permit, we shall take the liberty to lay before our readers a brief account of the contents of the Voluspa, which is indeed the text of the Scandinavian mythology.

The Voluspa.

The word *Voluspa* imports, "the prophecy of Vola or Fola." This was, perhaps, a general name for the prophetic ladies of the North, as Sibyl was appropriated to women endowed with the like faculty in the South. Certain it is, that the ancients generally connected madness with the prophetic faculty. Of this we have two celebrated examples; the one in Lycophron's Cassandra, and the other in the Sibyl of the Roman poet. The word *vola* signifies "mad or foolish;" whence the English words *fool*, *foolish*, *folly*. *Spa*, the latter part of the composition, signifies "to prophecy," and is still current amongst the common people in Scotland, in the word *spae*, which has nearly the same signification.

The Voluspa consists of between two and three hundred lines. The prophetess having imposed silence on all intelligent beings, declares that she is about to reveal the works of the Father of nature, the actions and operations of the

gods, which no mortal ever knew before herself. She then begins with a description of the chaos; and then proceeds to the formation of the world, and the creation of the different species of its inhabitants, giants, men, and dwarfs. She then explains the employments of the fairies or destinies, whom the northern people call *normies*, the functions of the deities, their most memorable adventures, their disputes with Loke, and the vengeance which ensued. She at last concludes with a long, and indeed animated description of the final state of the universe, and its dissolution by a general conflagration. In this catastrophe, Odin, and all the rabble of the Pagan divinities, are to be confounded in the general ruin, no more to appear on the stage of the universe; and out of the ruins of the former world, according to the Voluspa, a new one shall spring up, arrayed in all the bloom of celestial beauty.

Such is the doctrine exhibited in the fabulous Voluspa. So congenial are some of the details therein delivered, especially those relating to the final dissolution of the present system, and the succession of a new heaven and a new earth, that we find ourselves strongly inclined to suspect, that the original fabricator of the work was a semi-pagan writer, much of the same complexion with the authors of the Sibylline oracles, and of some other apocryphal pieces which appeared in the world during the first ages of Christianity.

In America, the only mythological countries seems to be Mexico and Peru. The other parts of that large continent were originally inhabited by savages, most of them as remote from religion as from civilization. The two vast empires of Mexico and Peru had existed about four hundred years only before the Spanish invasion; but in neither of them was the use of letters understood; and of course the ancient opinions of the natives relating to the origin of the universe, the changes which succeeded, and every other monument of antiquity, were obliterated and lost. Clavigero has indeed enumerated a crowd of sanguinary gods worshipped by the Mexicans; but he produces nothing either entertaining or interesting with respect to their mythology. Humboldt has gone deeper into the subject, and produced much information that is equally curious and instructive; whilst subsequent travellers, following his example, and extending their inquiries and researches, have thrown new light on both the mythology and antiquities of Mexico. See Mexico.

The only remarkable piece of mythology in the annals of the Peruvians, is the pretended extraction of Manco Capac the first Inca of Peru, and of Mama Ocolla his consort. These two illustrious personages appeared first on the banks of the lake Titicaca. They were persons of a majestic stature, and were clothed in decent garments. They declared themselves to be the children of the Sun, sent by their beneficent parent, who beheld with pity the miseries of the human race, to instruct and to reclaim them. Thus we find that these two legislators availed themselves of a pretence which had often been employed in more civilized regions for the very same purposes. The idolatry of Peru was gentle and beneficent, that of Mexico gloomy and sanguinary. The principle of good predominated in the one, the principle of evil in the other. The former borrowed its complexion from the character of its founders; the latter assumed the dark and repulsive aspect of the tyranny which it was intended to cement and consolidate. In a word, the idolatry of Mexico stood to the idolatry of Peru in a relation somewhat analogous to that which the wild and savage superstitions of the northern nations bore to the more refined and graceful mythology of Greece and of Rome.

In the course of this article, we have not much enlarged upon the mythology of the Greeks and Romans; that subject we conceive to be so universally known by the learn-

Mythology.

Mytilene

Myus.

ed, and so little valued by others, that a minute discussion of it would be altogether superfluous. We flatter ourselves, however, that in the course of this disquisition we have thrown out some reflections and observations which may perhaps prove more acceptable to both descriptions of readers, and serve to direct their attention to a subject which is yet far from being exhausted. (D. D.)

Mzensk.

MYTILENE, or MITYLENE (*Castro*), the most important city in Lesbos, was built on the E. coast of the island, on the neck of a peninsula. Its two excellent harbours, one on the N. and the other on the S. of the city, and its proximity to the mainland, rendered it at an early period the centre of the commerce and influence of the island. It is seen taking the lead in military enterprises as early as 606 B.C.; and its history soon becomes in general the history of Lesbos. The Mytilenæans were engaged in some of the greatest wars of antiquity. They furnished a contingent of sixty ships to Xerxes in his invasion of Greece, and they supported first the one side and then the other in the Peloponnesian war. On account of their share in this latter struggle their walls were thrown down, and their territory was occupied by the Athenians. The next important event in the history of Mytilene was its zealous espousal of the cause of Alexander the Great, a policy which brought upon it the attack of the Persians, under Memnon, in 333 B.C., and would have led to its capture, had not the hostile general died on the eve of victory. Still more unfortunate was its adherence to the cause of Mithridates. After a long siege it was taken and sacked by the Romans. Mytilene continued to flourish both during and after the dominancy of Rome. In the middle ages, so thoroughly had it concentrated within itself the wealth and influence of Lesbos, that it gave its name to the entire island. It retains part of its prosperity at the present day. (See *LESBOS*.)

MYUS, an Ionian town, situated in Caria, on the S. bank of the River Mæander, about 30 stadia from its mouth. It was founded, according to Strabo, by Cydrelus, a natural son

of Codrus; and in the days of that geographer its population, already very much lessened, had become incorporated with that of Miletus, and ceased to exist as a distinct political corporation. This desertion of their native town, on the part of the Myusians, is ascribed by Pausanias to the extraordinary number of flies which infested it, and which rendered the life of the inhabitants intolerable. Some think, however, that their removal was more probably owing to the numerous inundations to which, according to Vitruvius, their town was exposed. The King of Persia bestowed Myus, among other towns, upon Themistocles; and Philip of Macedon, after having made it his own, gave it to the Magnesians. We learn from Pausanias that this town possessed a beautiful temple, built of white marble, dedicated to Dionysus. Few traces of Myus now remain; and from the amount of debris annually carried down by the waters of the Mæander, and deposited at its mouth, the original distance of this ancient town from the sea has become very much increased; so that modern travellers have not unfrequently mistaken its site for that of Miletus, and erroneously identified Heracleia with Myus. (See *Leake's Asia Minor*; *Fellows' Journal of a Tour in Asia Minor*; and *Smith's Dictionary of Greek and Roman Geography*.)

MZENSK, a town of Russia, in the government of Orel, is situated at the confluence of the Mzena and the Zoucha, 35 miles N.N.E. of Orel. It is pretty well built, but principally of wood; and has twelve churches and two convents. There is a considerable trade here in corn and hemp, which are grown in the neighbourhood. Pop. (1851) 12,775.

N.

N
Nabis.

N is the fourteenth letter of the English alphabet, and a liquid consonant formed by placing the tongue against the line of junction between the upper teeth and the palate, and causing the sound to pass mainly through the nasal passage. It is consequently a nasal letter, and an imperfect mute or semi-vowel. **N** has only one sound, and is almost silent after *m*, as in *hymn*. It is liable to interchange with *l*, *m*, and *s*, of which there are numerous examples in various languages. By the ancients **N** was used as a numeral, to signify 900; and with a dash over it (*N̄*), it represented 9000. (For the use of this letter in ancient and modern abbreviations, see ABBREVIATIONS.)

NAAS, a town of Ireland, county of Kildare, 18 miles S.W. of Dublin. It consists of a main street and several smaller ones, and is not very well built. It has a parish church, a Roman Catholic, and an Independent chapel; a market-house, court-house, prison, barracks, hospital, dispensary, and several schools. Some remains are still to be seen of an ancient palace, which was the residence of the kings of Leinster, and in the neighbourhood there is a mount, or *rath*, of Danish origin. The name of the town, which signifies "The Place of Elders," has arisen from the circumstance that the states of Leinster used to meet here in the sixth, seventh, and eighth centuries. Naas is inferior in prosperity to many other towns in Ireland not so advantageously situated, and has been for some time in a declining state. A small trade is carried on in grain, provisions, and poultry. The county assizes are held here in spring, and at Athy in summer. Pop. (1851) 2971.

NABIS, a Spartan tyrant, usurped the supreme power in Lacedæmon on the death of Machanidas, at the battle of Mantinea, in 207 B.C. His government was established on a system of unbridled cruelty and rapacity. The most influential citizens were put to death or were driven into exile; temples were plundered; and the wealthy were subjected to exorbitant taxes. If they refused to pay, they were summoned before the tyrant. If their obstinacy still continued, a new engine of torture, made in the form of a woman, and having its breast and arms bristling with spikes, was forthwith produced. "Perhaps," said Nabis, "my wife Apega will be able to persuade you." They were then subjected to the horrid embrace of this automaton, and were tortured into compliance. With the money extorted in this manner the tyrant hired the services of all the vagabonds, ruffians, and cut-throats of the country. Some of these were sent to prowl and plunder throughout all parts of the Peloponnesus; others were employed to dog the footsteps of any dangerous Spartan exile, and to murder him as he fled along the way, or sat in fancied security in some friendly city; the rest were organized into a formidable mercenary army for the support and extension of the tyrant's power.

After this ruthless despotism had awed Sparta into submission, Nabis began to turn his thoughts to foreign conquest. His great project was to regain the Lacedæmonian ascendancy in the Peloponnesus. He began his attempt by invading the territories of Megalopolis, and by then seizing upon Messene. The skilful strategy of Philopœmen, the leader of the forces of the Achæan League, drove him back within his own domains in 201 B.C.; yet in the following year his army was again in the field, and was laying close siege to Megalopolis. About the same time he was pretending to favour the cause of Philip of Macedon against the Romans, that he might obtain possession of Argos. In 198 B.C. he attained his object, and then immediately struck a treaty with the Roman general Flaminius. This deceitful time-serving, however, did not prepossess his new allies in his

favour, and they seized the earliest opportunity to break the truce. In 195 B.C., the year after peace had been concluded between Rome and Philip of Macedon, Nabis received intelligence that Flaminius was marching against him. The most decisive measures for resistance were forthwith taken. To secure the fidelity of his troops, eighty suspected persons were put to death for the sake of example. The defences of Sparta were greatly strengthened; yet after the Lacedæmonians had been twice defeated under their own walls, their capital was forced to capitulate. A treaty was ratified, which deprived Nabis of the fruits of his deceit and aggression, and imposed upon him other severe penalties. The Romans, however, had not long departed from Greece when Nabis broke the truce, and marching southward, laid siege to Gythium. A fleet under Philopœmen, the general of the Achæan League, attempted to relieve the town. With a few ships, hastily collected, he completely frustrated the attempt, and compelled the enemy to retreat. The town was soon afterwards taken. Then hastening northward by forced marches, he succeeded in surprising Philopœmen, who was advancing upon Sparta. But the able Achæan general, instantaneously retrieving the surprise, outwitted his foe in return, cut his army to pieces, and ravaged the country unopposed during the ensuing month. For some time Nabis lay at Sparta, too weak to take the field again. At length, in 192 B.C., he received some Ætolians as a pretended reinforcement. They had come, however, in reality to effect his ruin; and he was assassinated by their leader Alexamenus. The ultimate consequences of his death were, that the Ætolians were massacred in their turn, and Sparta joined the Achæan League.

NABLOOS, or **NABULUS**, a town of Palestine, in the pashalic of Acre, beautifully situated at the N.E. foot of Mount Gerizim, 30 miles N. of Jerusalem. It is a long and narrow town, with two main streets: and the houses are high and well built of stone. Almost the whole of the streets have a busy and lively appearance; and along one of them runs a stream of clear water. The town contains the remains of an old church in the Byzantine style, with a fine gateway. There are also several mosques and bazaars, the latter of which are well supplied with silk and cloth from Aleppo, Baghdad, and Damascus. Some trade is carried on by means of the caravans which pass this way. Soap and cotton cloth are manufactured here. Nabloos is believed to occupy the site of the ancient Shechem, and derives its name from *Neapolis*, the title given to it when restored by the Romans in the time of Vespasian. There are some ruins on Mount Ebal, a short distance to the N.; and the tombs of Joseph and Joshua, as well as Jacob's well, are to be seen there. Pop. estimated at 8000.

NABONASSAR, first king of the Chaldæans or Babylonians, whose name marks an era commencing 26th February 747 B.C. (See CHRONOLOGY.)

NACHITSHEVAN, a town of European Russia, government of Ekaterinoslav, on the right bank of the Don, 7 miles E.N.E. of Rostov. The houses are well built, and the streets are broad, straight, and clean. It is the seat of an Armenian archbishop, and contains three churches, a convent, an Armenian school, and a printing-office. There is also a bazaar, which is well stocked with Indian and Persian goods. Manufactures of silk, cotton, leather, soap, brandy, and other articles, are carried on here; and there is an active trade, which is chiefly in the hands of Armenian merchants. Goods are brought from Turkey to supply the fairs of all the neighbouring provinces; and commercial intercourse is also carried on with Turkestan. Pearls and

Nabloos
||
Nachitshevan.

Nachitshevan || **Nagasaki.** precious stones are the most profitable articles of commerce here. The town was founded in 1780 by Catherine II., and is almost exclusively peopled by Armenians. Pop. (1851) 14,160.

NACHITSHEVAN, a town of Asiatic Russia, in the province of Erivan, occupies a lofty plain, near the Aras, 175 miles S. of Tiflis, and 64 S.E. of Erivan. It has three churches and a town-house; carries on the manufacture of leather and of earthenware; and is also a place of some trade. It was formerly the chief town in Armenia, but has recently much declined, and seems to have been much injured by the earthquake which took place in 1840. Pop. (1851) 5157.

NADIR SHAH. See **PERSIA.**

NÆVIUS, **CNEIUS**, one of the earliest of Roman poets, is generally supposed to have been a native of Campania, and to have been born in the former half of the third century B.C. He served in the first Punic war, and was thus an eye-witness of those exploits which he afterwards described. On his return to Rome, his literary career was commenced by the production of a drama, in the style introduced a few years before by Livius Andronicus. He continued to write many plays, both tragic and comic, which are known to us only by their titles, and by some of their fragments quoted in other authors. Several of his comedies, if we may judge from their names, seem to have been adapted from the Greek. It is certain, at least, that they lampooned the Roman aristocracy after the bold, sarcastic manner of the early comic poets of Greece. A fragment preserved by Gellius commences with a grandiloquent eulogy on the great deeds and matchless renown of the elder Africanus, and ends suddenly with a low scandal about his incontinence. In another quotation, the Metelli are declared to have been elected consuls merely by the evil genius of Rome. This latter cut was retaliated by the Metelli. They arraigned Nævius for the capital offence of libel. Barely escaping with his life, he was thrown into prison. There he was suffered to lie until he had written two plays for the purpose of retracting the imputations of which he had been convicted. His satirical spirit, however, was not tamed. Soon after his release he was caught in his old offence, and was sentenced to exile. He repaired to Utica, and there he spent the close of his life in composing his epic on the first Punic war. His death took place, according to Cicero, in 204 B.C. (*Tusc. Quest.* i., c. 1.)

The poetry of Nævius was still popular in the Augustan age. His humour is praised by Cicero in the *De Oratore*. So highly esteemed was the *Bellum Punicum*, written though it was in the antiquated Saturnian metre, that Virgil is said to have borrowed from it the description of the storm, and the conversation between Jupiter and Venus, in the first book of the *Æneid*. Horace also, in his second epode, talks of Nævius, who, "though not in the hands, is still in the minds of men." The fragments of Nævius were published among the *Fragmenta Poetarum Latinorum*, 8vo, Paris, 1564. They were also published separately by Klussmann, 8vo, Jena, 1843.

NAGASAKI, or **NANGASAKI**, a seaport-town of Japan, in the island of Kiu-siu, is situated on a peninsula formed by the Bay of Ohomura, on the west coast of the island; N. Lat. 32. 43., E. Long. 129. 51. It is built with considerable regularity on the slope of a hill, and the streets are broad and clean. The houses, which seldom exceed one storey in height, are constructed of a mixture of clay and straw on a framework of wood; and are covered with a cement that has the appearance of stone. The place of glass is supplied in the windows by strong oiled paper. Most of the better sort of houses have a large portico in front, and the back part of the house, where the family live, projects in a triangular form into a garden. The gardens, which are attached to all the houses of Nagasaki, are

generally laid out in a picturesque style, with rocks, trees, and waterfalls. In most of them there is also a small chapel. The slight materials of which the houses are built render them very liable to fires, which are frequently very destructive to the town. In order to provide against these, there is generally a detached storehouse, all the wood-work of which is thickly covered with clay, and there is also kept at hand a large vessel of liquid mud with which to besmear the walls in cases of danger. In these storehouses the inhabitants keep their most valuable property. The principal buildings in Nagasaki are,—the palaces of the princes of the empire and of the government officials; the numerous *ya siros*, or temples, in the town and neighbourhood; theatres; and tea-houses. The temples are surrounded with pleasure-grounds, which are much resorted to; and attached to them are large apartments, used for the accommodation of travellers or for banquets, and let out for such purposes by the priests. The Chinese factory stands in the southern suburb, and that of the Dutch in the island of Dezima, which is connected with the land by a bridge of stone. To this island, not more than 200 yards in length and 80 in breadth, the Dutch were for a long time strictly confined, and were not allowed to erect anything more substantial than wood and bamboo buildings on it. Beyond it they might not go, except with the permission of the governor of the town, to whom they must give twenty-four hours' previous notice; and when leave was obtained, each man was attended by a large number of official spies, all of whom had to be entertained at his expense. These restrictions, however, have been modified by the treaty concluded between the Dutch and the Japanese, 9th November 1855, which allows the Dutch full liberty to leave the island of Dezima. Nagasaki is now also open to the English, Americans, and Russians. The harbour affords good anchorage, and is deep, safe, and well sheltered. It is about 7 miles in length, by 1 in breadth, and has a depth of 5 or 6 fathoms. The estimates of the population vary considerably, but it is probably about 70,000.

NAGPORE, in Hindustan, a large town of the Deccan, and the principal place of the British province of the same name. It is about 7 miles in circumference, but very straggling and irregular, and possesses but one good street, the others being mean and narrow. The greater part of the houses are built of mud, some being thatched, and others tiled; but there are a few of large size built of brick and mortar, with flat-terraced roofs. Throughout the town there is no specimen of fine architecture; and even the palace of the former rajahs, which is the most considerable building, is totally devoid of symmetry or beauty. According to the last census the dwellings were,—thatched huts, 14,680; tiled houses, 11,120; houses of brick and mortar, 1301; making a total of 27,101, inhabited by a population amounting to 111,231, of whom about 2½ per cent. were Mohammedans, and the rest Hindus. The town is distant from Bombay, N.E., 440 miles; from Calcutta, W., 605; Lat. 21. 10., Long. 79. 10.

The British province, of which this town is the chief place, is bounded on the N. by the Saugor and Nerbudda territory, on the E. by the British districts of Sumbulpore and Odeipoor, and on the S.W. and W. by Hyderabad, or the territories of the Nizam. It lies between Lat. 17. 50. and 23. 5., Long. 78. 3. and 83. 10.; and contains an area of 76,432 square miles, with a population of 4,650,000. The principal rivers are,—the Wyne Gunga, the Mahanuddee, the Wurda, the Kanhan, and the Sew.

The rajahs of Nagpore, now an extinct dynasty, were the rulers of a state which was a branch of the great Maharratta confederacy and the heritage of a family distinguished by the appellation of Bhoonsla. Its founder was Parsojee, originally a private soldier, but who rose to power through the gratitude of Rajah Saho, the son of Sevajee, whose

Nagy. standard he was the first to join, when that chief was liberated from the captivity in which he had been held by the Emperor of Delhi. Ragojee, one of the successors of Parsojee, united his forces in 1803 with those of Scindia in the war against the British consequent on the treaty of Bassein. The victories of Assaye and Argaum compelled him to sue for peace, and by a treaty concluded in 1804 he surrendered the province of Cuttack. Upon the death of Ragojee in 1816, the reins of government were assumed by his cousin, the notorious Appa Sahib. This prince concluded a treaty with the British government, but shortly afterwards he entered into intrigues with the Peishwa, with whom the British were then at war, and on the 26th November 1817 he consummated his treachery by an open attack on the British troops at Seetabuldee, an eminence on the outskirts of the town of Nagpore. The disproportion of numbers was great, a British force of 1400 strong being opposed to a body of native troops amounting to 20,000; but the best dispositions which the suddenness of the attack allowed were promptly made. A noble charge, headed by Captain Fitzgerald with a small party of cavalry, upon a large body of the enemy's horse, decided the fortune, of the day. The British resident, Mr Jenkins, was on the ground throughout the day. His first assistant, Mr Sotheby, also repaired to the scene of action, and was there killed. After a contest of eighteen hours, the conflict terminated in favour of the British. Appa Sahib subsequently entered into fresh hostilities, and was ultimately deposed. The vacant throne was supplied by the elevation of a youth descended from Ragojee. The latest engagement made with this prince was in 1829. He died on the 11th December 1853 without issue. The succession in the Bhoonsla family was hereditary in the entire male line from the first founder of the dynasty, to the exclusion of females. There was no one who could pretend to this qualification, and Nagpore was consequently incorporated with the territories of the East India Company, and now forms a constituent part of the British dominions.

NAGY, a word, signifying in the Hungarian language "great," prefixed to the names of several places in Hungary and Transylvania.

NAGY-BANYA, a town of Hungary, in the county of Szathmar, 28 miles E.S.E. of the town of that name. In the neighbourhood there are gold, silver, and lead mines; and the town contains a mint, a mint inspector's office, and a chief office for mining. Nagy-Banya has also manufactories of earthenware, linen and cotton factories, smelting furnaces; and an active trade in litharge, chest-nuts, &c. Pop. 5300.

NAGY-BECSKEREK, a market-town of Hungary, in the county of Torontal, 40 miles S.W. of Temesvar. It contains the ruins of an ancient castle, has a Protestant grammar school, and silk-mills; and trades to some extent in agricultural produce. Pop. 15,500.

NAGY-ENYED, *Egidstadt*, or *Strassburg*, a market-town of Transylvania, not far from the Maros. It is the seat of a superintendent and consistory of the Reformed Church, and contains a college, with a library and museum. The manufacture of paper and the cultivation of the vine are carried on here. Pop. 5500.

NAGY-KAROLY, a town of Hungary, in the county of Szathmar, 44 miles N.E. of Grosswardein. It has a large palace and gardens belonging to the dukes of Karoly, a college, school, and linen and cotton factories. Vines, maize, and tobacco are grown in the vicinity. Pop. 12,000.

NAGY-KÖRÖS, a town of Hungary, in the county of Pesth, is situated in a sandy country, 40 miles S.E. of Pesth. It contains a school. Horned cattle and sheep are raised, and the vine cultivated, in the neighbourhood. Pop. 18,000.

NAGY-SZEBEN. See HERMANNSTADT.

NAGY-VARAD. See GROSSWARDEIN.

NAIADS. See NYMPHS.

NAIGEON, JACQUES ANDRÉ, a French encyclopædist, was born at Paris in 1738. After acquiring some knowledge of philosophy and of the exact sciences, he was introduced into the famous society of atheists and deists that gathered round Diderot and Baron d'Holbach. Henceforth Naigeon was the aping pupil and devoted worshipper of Diderot. He spoke and wrote nothing which he had not received in responses from the mouth of his oracle. He even assumed the gestures and voice of his great model. This slavish disposition prevented his common-place intellect from rising above the offices of editor, translator, and compiler. Besides his editions of Fontaine, Racine, and Montaigne, and other standard works, he published the works of Diderot, accompanied with an indifferent and unsatisfactory memoir of that author. He also edited many philosophical rhapsodies which their writers themselves, through very shame, had not avowed. His encyclopedic contributions, the chief of which is his "Dictionary of Philosophy, Ancient and Modern," in the *Encyclopédie Méthodique*, scarcely deserve to be called anything else than compilations. Naigeon died at Paris in 1810.

NAILS. Iron nails may be *wrought*, *cast*, or *cut*. Wrought nails may be forged from iron rods, which are now often prepared from plates rolled for the purpose, by slitting them into *nail-rods*, or *split-rods* of various sizes and qualities, by means of splitting rollers. For *horse-shoe nails* the best refined iron is used, to allow them to be drawn out fine, and not break in the hoof; *wheel-wright's nails* and *hurdle-nails* require to be made of a tough fibrous iron. Nails are variously named according to their shapes, or the uses to which they are applied. There are upwards of three hundred varieties of nails, and at least ten different sizes for each variety. A few of the principal forms are as follows:—1. *Rose-sharp*, a kind much used for coopering, fencing, and other coarse purposes in hard wood. A thinner sort, called *fine rose*, is used for softer woods, the broad spreading heads serving to hold the work down. 2. The *rose* with *flat* or *chisel* points, which being driven with their edges across the grain, prevent splitting. 3. *Clasp-nails*, where the heads projecting downwards clasp the fibres. 4. *Clout-nails*, with flat circular heads, round shanks, and sharp points, are used for nailing iron-work, &c., to wood. 5. The *counter-clout* is counter-sunk under the head, and has a chisel point. It is used by wheel-wrights and smiths. 6. *Fine-dog*, and *strong* or *weighty dog nails*, are used for nailing down stout iron-work, &c.; they have round shanks and spear-points. 7. The *Kent-hurdle*, used for nailing and clenching hurdles; *gate-nails* are similar in form. 8. *Rose-clench*, much used in ship and boat building; they have square ends, so as to punch out their own holes, and the ends are *clenched* by hammering, sometimes with the addition of a small diamond-shaped metal plate called a *rove*. 9. *Horse-nails*, with counter-sunk heads, so that they may lie flush in the groove made for them in the horse-shoe. 10. *Brads* and *tacks* also form useful and numerous varieties of nails. Nails of cast-iron are brittle, but very cheap, and are adapted to such purposes as fixing the lathing of plasterers, nailing up trees to garden walls, nailing stout shoes, boots, &c. Immense quantities of nails are also made by cutting and punching. (C. T.)

NAIRN, a parliamentary and municipal burgh of Scotland, capital of the county of the same name, is situated on the left bank of the River Nairn, near its mouth, and 16 miles N.E. of Inverness. It contains a town-house and jail, and possesses a harbour adapted for fishing-boats and small vessels. The first charter of the burgh now extant is one granted by James VI., bearing to be a renewal of a charter by Alexander I. Nairn is governed by a provost and 17 councillors. By railway it is connected with Inverness, and the line between it and Aberdeen is now

Naiads
||
Nairn.

Nairn-
shire.

all but completed. Markets on Tuesday and Friday. Pop. (1851), parliamentary burgh, 2977; municipal burgh, 3401.

NAIRNSHIRE, a small maritime county of Scotland, on the Moray Firth, which bounds it on the N., while on the other sides it has the counties of Inverness and Moray. It is 18 miles in length by 10 miles in breadth, and contains an area of 137,500 acres. The coast, which is about 9 miles in length, is low, bare, and sandy, and is rendered dangerous in its approaches by the numerous sand-banks. Sand-hills occupy the greater part of the coast district, and extend into Morayshire. A short distance from the shore, however, a bluff terrace-bank rises to the height of 90 feet, from which the country stretches in an undulating plain to a chain of hills from 4 to 5 miles inward. This level district consists of a great deposit of sand and gravel, rendering the soil light and porous. The hills in the interior, which attain a height of 1500 feet at the frontiers of Inverness-shire, are skirted where they border this plain by a strip of Devonian associated with a coarse conglomerate formation. The mountains themselves, however, are composed of granite and gray gneiss, with occasional beds of bluish granular limestone. The only important rivers in the county are the Nairn and Findhorn, neither of which are navigable. Rising from the Strathnairn Hills in Inverness-shire, the former enters the county at Clava, and discharges itself into the Firth at Nairn, after a course of about 30 miles. The Findhorn traverses the southern part of the county, and enters Morayshire at Dunduff. Agriculture was formerly in a very backward state here, but for the last ten years it has been making good progress. Like the neighbouring county of Morayshire, its arable land is restricted to the level country near the sea-shore; while the highlands of the interior are devoted to pasturage. The breeds of cattle and sheep, and the modes of tillage here adopted, are much the same as those of the adjacent county. Arable farms average 70 acres in extent; and the number of occupants of such were 426 in 1857. In the same year there were 30,311 acres under tillage in Nairnshire, of which 7346 acres were under oats, 4678 turnips, 3182 barley, 2062 wheat, 1407 potatoes, and 10,810 acres of grass and hay under rotation. The number of live stock in the same year were,—sheep, 35,985; cattle, 8966; horses, 1932; and swine, 1420. The old valued rent of the county was L.1263, while that of 1856 was L.23,960. Nairnshire having no good harbours, has not the same advantages of communication by sea as the neighbouring counties. The Great North of Scotland Railway, however, traverses the northern portion of the county, and connects it with Inverness on the one hand, and Aberdeen and the south on the other. The county unites with Morayshire in returning a member to Parliament. It belongs to the northern circuit, and the assizes are held in Aberdeen; while, ecclesiastically, the county pertains to the synod of Nairn. In 1851 there were 10 places of worship in Nairnshire, 3 of which belonged to the Established, 4 to the Free, 2 to the United Presbyterian, and 1 to the Independent denominations. Education in the same year was communicated in 21 schools, 7 of which were private seminaries. The number of poor who received relief in the year ending 14th May 1856 amounted to 315, and the sum collected for this purpose was L.1710, against L.1801 expended. The population of Nairnshire was, in 1831, 9354; in 1841, 9217; and in 1851, 9956; of which last 4695 were males, and 5261 females. It contained only one town, Nairn, the capital, with more than 2000 inhabitants. This county, which anciently belonged to the province of Moray, contains a few remains of antiquity. Among these are Finlay and Rait castles, in the parish of Nairn; and the celebrated Cawdor Castle which is still entire, and is one of the seats of the Earl of that name.

NAMAQUA LAND forms the western portion of the country of the Hottentots in South Africa, and is divided into Great and Little Namaqua Land; the former lying to the N., the latter to the S. of Orange River.

NAMUR, a province of Belgium, is bounded on the N. by South Brabant, E. by Liège and Luxembourg, S. by France, and W. by Hainault. Its length from N. to S. is 55 miles, greatest breadth 45; area 1409 square miles. The surface of the province is much varied by hill and dale, and in some parts, especially in the valley of the Meuse, between Namur and Liège, the scenery is extremely beautiful and romantic. The principal rivers are the Meuse, and its tributary the Sambre, which joins it at Namur; the former flowing from the S., and the latter from the E. In a geological view, nearly the whole of this country belongs to the Carboniferous system, and contains strata of limestone, sandstone, coal, and iron. The iron mines of Namur are very rich, and employ a large proportion of the industry of the province. There were in 1855, 25 coal-pits in this province, producing coal to the value of L.74,000. Lead mines are also worked to some extent; and building-stone, slate, and marble are quarried. The soil for the most part consists of a rich marl of no great depth. It is very fertile, and well cultivated; about one-half of the whole extent being under cultivation, and one-third occupied by wood. Wheat, rye, oats, barley, fruits, hemp, flax, and chicory are the principal crops raised in some parts; vines are also grown. Oak, beech, ash, hornbeam, birch, and hazel, are the principal trees in the forests; and these supply excellent timber, and wood for fuel. The forests of the province abound in game, and the rivers in fish. Large numbers of horses are reared, which are strong and of good breed. The principal manufacture of Namur is cutlery, for which the province is famed; and trade is actively carried on. The province is divided into three arrondissements,—namely, Dinant, Namur, and Philippeville; and had in 1856 a population of 286,075.

NAMUR (Flem. *Naemen*, Germ. *Namen*), a town of Belgium, capital of the province of that name, is situated at the confluence of the Meuse and the Sambre, 35 miles S.E. of Brussels. Defended by walls of considerable thickness, by well-constructed outworks on both sides of the rivers, and by a castle which stands on a rocky eminence at their junction, it is a place of great strength. The streets are broad and clean, and there are several fine squares. The houses are well built of stone, and covered with slates. There are two bridges, one across each river; and the town is entered by 11 gates. The cathedral of Namur is a fine modern building in the Corinthian style, adorned in front with several statues in white marble. In the interior the most remarkable objects are the statues of St Peter and St Paul, on each side of the great altar; and the pulpit, which is adorned with very fine carving in oak. This church contains the tomb of Don John of Austria, natural son of Charles V., and famous as the conqueror of the Turks at the battle of Lepanto. The church of St Loup is also a fine building, richly adorned in the interior with marble and carving in stone. Namur contains several other churches, a town-hall, several schools, an atheneum, an academy of painting, and a public library; a deaf-and-dumb asylum, and other charitable institutions; a penitentiary, arsenal, barracks, &c. The manufactures are considerable, and of these, cutlery is the principal; so that the town has been called the Sheffield of Belgium. Its productions in this branch of industry are more nearly equal in quality to those of Sheffield than those of any other town on the Continent. The manufacture of leather is also largely carried on; and a great number of the inhabitants are employed in the mines and quarries of the neighbourhood. The situation of Namur gives it great commercial advantages; and a consider-

Namaqua
Land
||
Namur.

Nancowry able export trade is carried on. Steamers ply on the Meuse as far up as Liège, with which town Namur is also connected by railway, as well as with Brussels and Paris. Namur has suffered much from the ravages of war. It was taken by Louis XIV. in 1692, an event which was recorded by Racine, and celebrated in verse by Boileau; but was recovered in 1695 by the British and Dutch under William III., after a siege of ten months. The fortifications were destroyed in 1784 by Joseph II. of Austria; but restored and strengthened in 1817 under the inspection of the Duke of Wellington. Pop. 22,218.

NANCOWRY, one of the Nicobar Islands, in the Bay of Bengal, N. Lat. 7. 57, E. Long. 93. 43. The soil is rich, and produces cocoa-nuts, plantains, limes, bread-fruit, tamarinds, and other tropical fruits. The inhabitants exchange poultry for cloth, cutlery, tobacco, and other articles. There is a large and good roadstead between this island and those of Camorta and Trincutty. The island is about 25 miles in circumference.

NANCY, a town of France, capital of the department of Meurthe, is situated in a beautiful and fertile plain, bounded by wooded hills, on the left bank of the Meurthe, 177 miles E. of Paris. It is one of the finest towns of France, not only on account of the beauty of its environs, but for its fine public walks and splendid buildings. It consists of an old and a new town; the former of which is irregularly built, with narrow and gloomy streets, although it contains some fine private houses and most of the public buildings. The new town consists of wide and regular streets, lined with handsome houses. There are several fine squares, of which the principal is the Place Royale, bordered on three sides by the town-hall, the episcopal palace, the theatre, and the custom-house. This square is adorned with four elegant fountains at the corners; and has in the centre a statue of Stanislas Lesczynski, King of Poland and Duke of Lorraine, to whom the town owes many of its improvements and embellishments, and among the rest a very fine, triumphal arch which leads from this square to the Place Carrière. Besides these, the Place d'Alliance, which has a beautiful fountain and a fine avenue of limes, and the Place St Epore, are worthy of mention. The principal public walk in Nancy is the Cours d'Orleans, extending from the Place de Grève to the Porte Neuve, one of the gates of the town, which is built in the form of a triumphal arch. The cathedral of Nancy is a handsome modern edifice in the composite style, with two towers surmounted by domes. The church of St Epore is also a handsome building, and contains some remarkable paintings and sculpture. The church of the Cordeliers contains, among other monuments, the mausoleum of the dukes of Lorraine, a beautiful marble structure of an octagonal form. Near this church are the remains of the palace, which was formerly the residence of the dukes of Lorraine, but is now used as a barrack. Besides the buildings already mentioned, the town contains a university, with a library of 23,000 volumes, a theological college, a school of medicine, an academy, a normal school, an agricultural society, school of design, botanic garden, &c. It is the see of a bishop; and has a court of appeal, a court of first instance and one of commerce, and a council of *prud'hommes*. The manufactures of Nancy are considerable,—consisting of cloth, hosiery, calico, lace, cotton, embroidery, muslin, paper, oil, wines, leather, and chemical substances. There are also dyeworks, and establishments for the refining of saltpetre. A considerable trade is carried on in its articles of manufacture, as well as in corn, wool, hides, iron, &c. Three yearly fairs are held. The origin of this town may be traced as far back as the tenth century. It was formerly the capital of Lorraine, and the residence of the dukes of that country. It was taken by Charles the Bold in 1475; but he lost it the year after, and in 1477

was killed in a battle with René II., Duke of Lorraine, under the walls of Nancy. Pop. (1856) 43,452.

NANGASAKI. See **NAGASAKI**.

NANI, or **NANNI GIOVANNI**, an eminent artist, was the son of a wealthy proprietor, and was born at Udine in 1487. From his birthplace he was often called *Da Udine*. He also inherited the surname of *Ricamatore* from his ancestors, who were famous embroiderers. His taste for painting was developed at a very early age. When he was wont to go out hunting or fowling with his father he never tired in sketching the figures of the dogs and the game. This decided bias induced his father to place him under the celebrated painter Giorgione da Castel Franco at Venice. In no long time, however, the young artist had grown so enthusiastic an admirer of Raphael, that he could not rest contented until he had repaired to Rome, and had become a pupil of that great master. His pencil soon began to acquire the soft, graceful, and beautiful manner of his teacher. He became an adept at imitating all natural objects, especially birds, foliage, fruits, and flowers. It was not, however, until the excavations in the palace of Titus had laid bare in the subterranean chambers the grotesque and stucco works of antiquity that Nani found the subject most adapted to his taste and genius. His whole time was forthwith unweariedly spent in studying and imitating these decorations. After many an experiment he succeeded in producing the stucco of the ancients, and in moulding it into copies of the antique which rivalled their originals. This success led Raphael to employ him in decorating the gallery of the Vatican. The ability with which he executed the stucco ornaments, and the ingenuity with which he enriched his decorations with foliage, shells, birds, and landscapes, brought him into great repute. He was employed by Leo X. to adorn, in a similar manner, some other halls and galleries. Then Giulio, the Cardinal de' Medici, taking him under his patronage, conferred upon him the dignity of a knighthood of San Pietro, and sent him to Florence to ornament a gallery in the Medici palace which had been designed by Michael Angelo. On his return to Rome he continued to prosecute his art with great success until the death of Leo X. in 1521. During the short and unpropitious pontificate of Adrian VI. Nani lived at his native Udine. On the accession of Pope Clement VII. in 1523, he was restored to his position in the public favour at Rome. A pension of eighty ducats was conferred upon him, and he was sent to Florence to decorate the new sacristy of San Lorenzo, which was already adorned with the noble sculptures of Michael Angelo. This elaborate undertaking was just on the eve of being completed when Pope Clement died in 1534, and Nani lost the hard-earned reward of his toil. He once more retired in disgust to Udine, and was employed for several years in painting and adorning with stucco-work several chapels and edifices in the neighbourhood. Of these works, the most notable which still exist are the picture of the "Virgin and the Child," on a rich banner belonging to the fraternity of Castello in his native city; and a chamber decorated with stucco-work and paintings, in the palace of the patriarch of Aquileia in Venice. Towards the close of his life he returned to Rome, and received employment from Pius IV. He died at the age of seventy-seven. (Vasari's *Lives of the Painters*, and Lanzi's *History of Painting*.)

NANKING, or **KIANGNING FU**, the ancient capital of China, now the chief town of the province of Kiangsu, and the residence of the governor-general of three provinces, is situated about three miles from the south bank of the Yang-tse-Kiang, about 100 miles from its mouth. This city was once the most celebrated in the empire, whether regarded as to its extent, its buildings, or its manufactures; but since the removal of the imperial residence to Peking

Nancy.

Nangasaki
Nanking.

Nantes.

by Kublai Khan in the end of the thirteenth century, it has very much declined. The walls at present surrounding the town are said to be about 20 miles in extent, but from existing remains those of the ancient town seem to have been about 35 miles in circumference. It is, however, impossible to say how much of the larger space was occupied with buildings; but at present not more than one-half of the area inclosed by the walls is actually occupied by the city. The ancient palaces have almost entirely disappeared, and the only remarkable monuments of royalty that now remain are some sepulchral statues of gigantic size, near an ancient cemetery known as the Tombs of the Kings. At some distance from these statues are a number of rude colossal figures of horses, elephants, and other animals.

Nanking consists of four rather wide and parallel avenues, which are intersected by others of less width, and are on the whole clean, well paved, and lined with handsomely-furnished shops. The town is very unhealthy, being situated in an extensive marshy plain, which, especially in the hot season, gives off noxious vapours. The three gates on the eastern side of the city are approached by three well-paved causeways. That part of the town occupied by the Manchos is separated from the Chinese town by a high wall. Nanking possesses no public buildings of importance, except the famous porcelain tower, an edifice superior to anything of the kind in the empire. It is of an octagonal form, each side being 15 feet wide; and is about 260 feet in height. Its base rests upon a solid foundation of brick-work, 10 feet high, up which a flight of twelve steps leads into the tower, where there is a spiral staircase leading to the top. The body of the edifice is composed of brick, the outer face of which is covered with slabs of glazed porcelain of various colours, principally green, red, yellow, and white. It consists of nine storeys, decreasing gradually in size to the top, and at each storey is a projecting roof covered with green tiles, with a bell suspended at each corner. Each storey forms a saloon, which is finely painted and gilt, and adorned with numerous gilded images. The whole is covered by a gilt conical roof, and from the summit rises a mast 30 feet in height, surrounded by an immense iron coil, and surmounted by a large gilded ball. This edifice was nineteen years in building, and was completed in A.D. 1430. The entire cost is said to have been about L.800,000.

Nanking has extensive manufactures of fine satin and crape, and of the cotton cloth called, after the city, *nankeen*. Paper and ink of fine quality, and beautiful artificial flowers of pith paper are produced here. The commerce of the city is very considerable, owing to its position near the great River Yang-tse-Kiang. It communicates with Peking by means of the Imperial Canal, which leaves the river about 40 miles below the city. Nanking is not less celebrated for literature than for its manufactures and commerce; and is considered one of the first places of learning in the country. The arts and sciences are studied here with great diligence; and its libraries are extensive and valuable. The booksellers' shops are well stocked with the best native publications, and the editions published here are the most esteemed in the empire. It was here that terms of peace were concluded between the English and Chinese in August 1842. Pop. estimated at about 400,000.

NANTES, an important commercial town of France, the seat of a bishop, and capital of the department of Loire-Inferieure, on the right bank of the Loire, about 30 miles from its mouth, 208 miles S.W. of Paris. N. Lat. 47. 13., and W. Long. 1. 32. It stands partly on the mainland, intersected by the Erdre and Sèvre-Nantaise, and partly on three islands formed by the irregular course of the Loire. Thus situated, the town enjoys the advantages of water-communication between its various quarters.

Nantes.

The old part of the town occupies the right bank of the river, and is divided into two portions by the Erdre, which forms the outlet of the Nantes and Brest Canal. Many of the houses here are antique and picturesque in appearance, but in the newer parts of the town the houses are generally elegant, and the streets spacious. The quays which line the river are extensive and commodious, and add much to the gay aspect of the town. But the most striking quarter of the city is that occupied by the boulevards of St Peter and St Andrew, and the Place Louis XVI. These, which are ornamented with rows of trees, stretch from the St Felix branch of the Loire to the Erdre, and form a delightful promenade. The islands of Feydeau and Gloirette, connected with the main and with each other by several bridges, are occupied by well built streets, while the latter has a dock and excellent quays. A larger island, in mid stream, is chiefly laid out in parks and private villas, and is also provided with a dock and quays. The chief public edifices are as follows:—St Peter's cathedral, commenced in 1434, is a plain though massive building near the centre of the town, and contains a very fine monument of Duke Francis II. of Brittany, and his spouse Margaret of Foix. This forms an altar tomb of marble, on which the effigies of the duke and duchess are recumbent, supported at each corner by statues of Power, Justice, Temperance, and Prudence. The castle, an old building of the fourteenth century, stands at the extremity of the boulevard of St Peter, close upon the river. It is still entire, is provided with a portcullis, and defended by a ditch. This fortress for long formed an occasional residence for the French kings, and it was here that the famous edict of Nantes was signed in 1598. The other buildings of note are—the gallery of paintings, the public library with 30,000 volumes, the natural history museum, and a new court-house. There is likewise a large new church called St Nicholas, in the Gothic style, which is nearly completed.

From its situation Nantes enjoys a large shipping trade, and ranks in importance as the fourth port in the empire. Manufactures have, from a like cause, much increased here, and comprise cotton yarn, refined sugar, serge, blankets, preserved provisions, &c. The imports include timber, pitch, raw cotton, iron, and coal; while the exports comprise corn and flour, wine, brandy, silk, paper, &c. Shipbuilding is likewise carried on to some extent, while several vessels are fitted out here for the whale and cod fisheries. From the numerous sandbanks which obstruct the Loire, vessels of more than about 300 tons burden must unload at Paimbœuf, 24 miles lower down the stream.

In the year 1855, 278,168 tons entered, and 236,034 tons cleared at the port. Of these numbers 139,518 tons entered, and 121,632 tons cleared, coastwise; while eight vessels with 982 tons entered from, and seven vessels with 1628 tons cleared to, the cod fisheries during the same year. Engaged in foreign commerce in 1855, 1143 vessels with 137,668 tons entered, and 649 vessels with 112,774 tons cleared, at the port. During the same year there were registered at the port 593 sailing vessels, with 87,440 tonnage, and 20 steamers, with 4124 tonnage. The amount and value of various articles imported here in 1855 were 83,100 tons, of the aggregate value of L.1,280,000. With the interior Nantes has abundant means of communication. The Loire is navigable for barges for many miles above the town, while a canal connects it with Brest on the one hand and St Malo on the other. A line of railway likewise brings the town within a few hours' distance of Paris. The city is governed by a civil tribunal, and the trade is regulated by a chamber of commerce.

The history of Nantes reaches back to the time of the Romans, when, under the name of *Condivicnum*, it formed

Nantucket
||
Nantwich.

the chief town of a Gallic tribe called the Nannetes. It seems to have remained in the hands of the Romans until the beginning of the fifth century, when they were driven from the town. The Normans captured it in 853 and 859, and held possession for nearly a century; after which the town suffered many sieges—in 1343 by the English; in 1380 by the Earl of Buckingham, when it was relieved by Oliver of Clisson; and again in 1491 by Charles VIII. This monarch afterwards espoused Anne of Brittany, with whom he obtained the province, and thereafter Brittany formed part of the French dominions. During the Reformation Nantes escaped the horrors of the great Huguenot massacre by the manly spirit of its chief magistrate, who resolutely refused to execute the bloody order sent him by the Duc de Montpensier. The famous edict of Nantes that followed this event was signed here in 1598 by Henri IV., but was afterwards revoked by Louis XIV. in 1685. More recently, the town suffered much from the Vendean civil war of 1793. In June of that year the Vendean army, 50,000 strong, under Cathelineau, laid siege to the city, then defended by Generals Beysser and Canclaux, but were repulsed with great loss—their general being among the slain. Cartier, one of the leaders of the republicans, about the same time committed the greatest atrocities on the inhabitants, who are said to have suffered during the civil wars a loss of from 6000 to 9000 men, women, and children. Nantes was the birthplace of Anne of Brittany, of the navigators Cassart and Caillaud, and of the naturalist Dubuisson. It was from Nantes that Prince Charles Edward embarked for Scotland in 1745. Pop. of Nantes (1851) 91,303; (1856) 101,019.

NANTUCKET, an island off the coast of Massachusetts, N. America, is situated 30 miles S. of the peninsula Cape Cod, and 10 E. of the island of Martha's Vineyard. It is of a triangular shape, 15 miles in length, by 4 in average breadth; area 50 square miles. The surface is level, with the exception of some hills in the southern part. The soil is generally sandy; but affords in some places good pasture. Maize, potatoes, and grass, are the principal crops raised on the island. The inhabitants are employed to a great extent in navigation and fishing, especially in the whale fishery. The town of Nantucket is situated on a bay in the N. coast of the island, in N. Lat. 41. 17., W. Long. 70. 6., and about 105 miles S.E. by S. of Boston. It is compactly built, with narrow streets and wooden houses; and contains 8 or 9 churches, 2 newspaper offices, a bank, and an atheneum with a library and museum attached to it. On the 13th of July 1846, the town was devastated by fire; and no fewer than 350 buildings were destroyed; among which were a church, 2 banks, the atheneum, and 7 oil and candle manufactories. The total loss was estimated at L.40,000; and the number of families who suffered by it was 450. Nantucket was the earliest town in the States to engage in the whale fishery, in which it holds a prominent position, but is still in this respect inferior to New Bedford. The registered tonnage of the port amounted in 1852 to 27,231; of which 18,015 tons were employed in whale fishing, 3048 tons in the coasting trade, 403 in the cod and mackerel fisheries, and 479 in steam navigation. About 2000 men are generally employed in whale fishing, and a capital of L.100,000 or L.120,000. The harbour of Nantucket is large, deep, and well sheltered by two promontories, which leave an entrance only three-quarters of a mile broad. A lighthouse with a fixed light stands on its south side. A steamer plies between Nantucket and New Bedford. Pop. 8452.

NANTWICH, a market-town of England, county of Chester, in a low, flat country, on the right bank of the Weaver, 17 miles S.E. of Chester. It consists of four principal streets; and the houses are for the most part old, and built of wood or brick. There is a fine church, in the

form of a cross, with an octagonal tower and a stone pulpit. Nantwich has also several dissenting churches, almshouses, several banks, a market-house, and a theatre. Salt was formerly the principal article of manufacture here, and was obtained from numerous springs in the neighbourhood; but only one of these is at present worked. The manufactures consist chiefly of cheese, shoes, gloves, and cotton. Some trade is carried on in cheese and other farm produce. A battle was fought at Nantwich in 1643, in which the royalists were defeated by the parliamentary troops under Fairfax. Nantwich was the birthplace of Gerard, a botanist, in 1545. Pop. (1851) 5426.

NAPAKIANG. See LOO CHOO.

NAPIER, SIR CHARLES JAMES, G.C.B., was the eldest son of Colonel George Napier, comptroller of accounts in Ireland, and was born at Whitehall on the 10th August 1782. At an early age he removed with the family to Celbridge, a small town on the Liffey, about ten miles from Dublin, and there he attended school. By this time he held a commission in the 4th regiment, and was longing for an opportunity to wield his warlike weapons. An opportunity occurred during the Irish rebellion of 1798; and the boy-soldier bore himself with all the self-confident courage of a man. For the next ten years the most prominent incidents in his life were the changes which he made from one regiment into another. In 1800 he changed into the Rifle corps; in 1803 he was promoted to the staff of General Fox; and in 1806 he became a major in the 50th regiment. About this time large squadrons of troops were embarking for the French war. The fiery Napier chafed under the order that kept him in ignoble ease at home. At length in 1808 his regiment was ordered to the Peninsula, and he arrived in time to fight under his favourite general Sir John Moore. On the field of Coruña he led the 50th into the thickest of the battle, and was left, covered with wounds, in the hands of the enemy. His friends gave him up for lost, and were already disposing of his effects, when he arrived in England on parole about two months after his capture. The reports of Wellington's victories soon rekindled his military enthusiasm, and in 1809 hurried him as a volunteer to the scene of war. For the next three years he shared in the perils and triumphs of the peninsular battles. He had two horses shot under him at Coa, and was taken up for dead on the field of Busaco. Promotion, hardly earned and long delayed, came at length in 1812, and drew him once more from active service. He was sent out to the Bermudas as lieutenant-colonel of the 102d regiment. A cruising expedition against America was fitted out in the following year, and Napier was appointed second in command. He was still employed in capturing vessels and making night descents on the coast of the United States, when the long-continued struggle with Napoleon was fast approaching a crisis. His return to Europe was hastened; but he arrived in time to find that the decisive blow had been struck three days before at Waterloo. With all its characteristic ardour his mind was next applied to study; and after an attendance of three years at the Military College he received a first certificate.

In 1825 Napier's talent for administration obtained for the first time a fair field of exercise, by his being appointed governor of the island of Cephalonia. His rule was characterized by an earnest and disinterested philanthropy. More than 100 miles of road were made; spacious streets were erected in the room of narrow dirty lanes; the administration of justice was reformed; and agriculture and commerce were encouraged and stimulated. At the same time, he co-operated with Lord Byron in the plan for the liberation of Greece, and would have accepted the offer of the chief command in that enterprise, had circumstances permitted. His career as a social benefactor was suddenly checked by his recall in 1830. Yet the Cephalonians com-

Napakiang
||
Napier.

Napier.

pletely annulled this implied censure by continuing to call him their father as long as he lived.

Napier had been for about two years commanding the military district of the north of England, and managing to suppress the Chartist demonstrations without bloodshed, when he was appointed commander of the Bombay army in 1841. On arriving at his destination, he found that the British cause was endangered by the recent defeats and disasters in Afghanistan. It therefore became his chief aim to retrieve the national reputation. With this view he drew up a plan for the Afghan campaign, which received the approbation of the newly-appointed governor-general Lord Ellenborough. In 1842 he entered into active service as commander-in-chief in Scinde. This province was then under the military despotism of the Ameers, who, under cover of an ill-defined and ill-understood treaty made with Lord Auckland, the late governor-general, were cruelly oppressing their subjects, and carrying on a cunning system of intrigues against the British power. To define this crude treaty, to elevate the Scindians from their abject slavery, and to bring their tyrants to bay, were now the difficult tasks to which Charles Napier, at the age of sixty, with a constitution shaken by wounds and disease, and under an oppressive climate, addressed himself. The enterprise went rapidly on towards a successful issue. Early in 1843 the Ameers found themselves convicted of perfidy, and forced to the alternative of signing a new treaty or of resorting to open warfare. They chose the latter. Napier was immediately on the field, and was already aiming a sudden and decisive blow. This was the capture of Emaum Ghur, a solitary fortress that stood in the middle of a waste wilderness of drifting sand, and was therefore considered the chief stronghold and ultimate refuge of the Ameers. By a laborious and ably-conducted march the British forces reached the desert castle, found it deserted, and shattered it to atoms with gunpowder. After thus achieving what the Duke of Wellington afterwards called "one of the most curious and extraordinary of all military feats," Napier returned to face the enemy in the field of battle. On the 17th February 1843 he confronted an army of 35,000 at Meeanee. To oppose this overwhelming force he had only 2000 raw soldiers. Yet his bold tactics and fiery courage inspired his men with a resistless valour. After a hard fight of four hours they defeated their foes, and drove them from the field. The Ameers resigned their swords, and the city of Hyderabad capitulated. In a short time, however, the conqueror was surrounded on all sides by hordes of wild Beloochees, and threatened in front by a large army under Shere Mohammed, surnamed "the Lion." Entrenching himself in Hyderabad, he dared his enemies to attack him, until he had contrived to procure a reinforcement. Then marching out at the head of 5000 men, he attacked and routed the 26,000 of "the Lion" at Dubba. "The Lion" retired to his native deserts, and soon returned with another army; but the brave barbarian was no match for the skilful English general. By the 8th June 1843 his force was hemmed in on all sides and forced to fight; his power was completely crushed; and the last blow was struck in the conquest of Scinde. Napier was now appointed governor of the province he had subjugated. Under the prostrating influence of the climate, the attacks of disease, and the more irritating attacks of intriguing malice, the old general began to rule the discordant elements of barbarism with the same fiery vigour and success with which he had swayed the fickle destinies of battle. The native laws were re-organized, an effective system of police was established, and all evil customs, such as suttee, infanticide, the murder of women, and the military tenure of land, were abolished. The Hindoo trader was protected, the Scindian slave was liberated, and the Beloochee cut-throat was tamed into a peaceful civilian. Commerce, suddenly springing

into new life, made her principal seat at Kurachee; and the province, which was little else than a hunting forest for the Ameers, became in a few years a well-cultivated land, waving with rich harvests and enlivened by industrious villages. This work of reform would have been carried out still further had not Sir Charles Napier been compelled by the declining health of his wife to return home in 1847. He had not enjoyed his retirement long when the news of the disasters of the Sikh war reached England. The general voice of the nation called upon Napier to save once more the British honour in India. He was reluctant to expose his reputation again to his enemies in the Indian government. But the Duke of Wellington's laconic argument, "If you don't go, I must," overcame his unwillingness. He embarked in March 1849, and in forty-three days was in Bombay. The war by this time had been successfully ended by Lord Gough; but there were abuses that Napier considered as dangerous enemies as the Sikhs. Applying himself resolutely to the invidious task of reform, he travelled through the country, suppressing a mutinous spirit among the sepoys, and schooling the British officers in a severer discipline. At the end of two years the venerable warrior returned to England, worn out by his life-long and ill-appreciated labours in his country's service. He died on the 29th August 1853 at his seat of Oaklands, near Portsmouth, surrounded by the trophies of his many campaigns.

Sir Charles Napier was the author of *Colonization in Southern Australia*, 8vo; *History of the Colonies—Ionian Islands*, 8vo; *Indian Misgovernment and Lord Dalhousie*, 8vo; *Lights and Shades of Military Life*, 8vo; and *Remarks on Military Law of Flogging*, 8vo. He was brother to the present Sir William Napier, and cousin to the present Admiral Sir Charles Napier. The former has written his *Memoirs* in 4 vols. 8vo, London, 1857.

NAPIER, John, Baron of Merchiston, the distinguished inventor of logarithms, was the eldest son of Sir Archibald Napier of Edinbellie and Merchiston, by his first wife Janet Bothwell, and was born at Merchiston Castle, near Edinburgh, in 1550. After passing through the ordinary courses of liberal study at the university of St Andrews, he travelled in France, Italy, and Germany. Upon his return to his native country, his accomplishments soon rendered him conspicuous, and might have raised him to the highest offices of state; but declining all civil employments, he retired from active life to pursue those scientific and literary researches in which he subsequently made such uncommon progress. He applied himself chiefly to the study of mathematics, and of the Holy Scriptures; and in *A Plain Discovery of the Revelation of St John*, his first publication, he displayed great acuteness and striking ingenuity, but did not succeed in fathoming the mysteries of the Apocalypse. This work was printed abroad in several languages, particularly in French at Rochelle in the year 1602, in a quarto volume, revised by himself. But what has rendered his name for ever illustrious was his discovery of logarithms. That he had begun before the year 1594 the train of inquiry which led to this great achievement, appears evident from a letter to Crugerus, written by Kepler in the year 1624, wherein, mentioning the *Canon Mirificus*, he writes thus:—"Nihil autem supra Nepierianam rationem esse puto; etsi Scotus quidem literis ad Tychonem, anno 1594, scriptis jam spem fecit canonis illius mirifici." This allusion agrees with the idle story mentioned by Wood in his *Athenæ Oxonienses*, and explains it in a way perfectly consonant to the rights of Napier as the inventor.

When Napier had communicated to Henry Briggs, mathematical professor in Gresham College, his wonderful Canon for Logarithms, that learned professor set himself to apply the rules in his *Imitatio Nepieræ*; and in a letter

Napier.

Napier. to Archbishop Usher, written in the year 1615, he thus expresses himself:—"Napier, Baron of Merchiston, hath set my head and hands at work with his new and admirable logarithms. I hope to see him this summer, if it please God; for I never saw a book which pleased me better, and made me more wonder." The following passage from the *Life of Lilly* the astrologer gives a picturesque view of the meeting between Briggs and the inventor of the logarithms, at Merchiston, near Edinburgh:—"I will acquaint you," says Lilly, "with one memorable story related unto me by John Marr, an excellent mathematician and geometrician, whom I conceive you remember. He was servant to King James I. and Charles I. When Merchiston first published his logarithms, Mr Briggs, then reader of the astronomy lectures at Gresham College in London, was so much surprised with admiration of them, that he could have no quietness in himself until he had seen that noble person whose only invention they were. He acquaints John Marr therewith, who went into Scotland before Mr Briggs, purposely to be there when these two so learned persons should meet. Mr Briggs appoints a certain day when to meet at Edinburgh; but failing thereof, Merchiston was fearful he would not come. It happened one day as John Marr and the Baron Napier were speaking of Mr Briggs; 'Ah, John,' said Merchiston, 'Mr Briggs will not come.' At the very instant one knocks at the gate: John Marr hasted down, and it proved to be Mr Briggs, to his great contentment. He brings Mr Briggs up to the Baron's chamber, where almost one quarter of an hour was spent, each beholding the other with admiration, before one word was spoken. At last Mr Briggs began:—"Sir, I have undertaken this long journey purposely to see your person, and to know by what engine of wit or ingenuity you came first to think of this most excellent help into astronomy, viz., the logarithms; but, Sir, being by you found out, I wonder nobody else found it out before, when now being known it appears so easy.' He was nobly entertained by the illustrious baron; and every summer after that, during the baron's life, this venerable man, Mr Briggs, went purposely to Scotland to visit him."

There is a passage in the *Life of Tycho Brahe* by Gasendi, which might lead some to suppose that Napier's method had previously been explored by Herwart at Hoenburg. But Herwart's work, published in 1610, solves triangles by prostaphæresis, a mode totally different from that of logarithms. Kepler, who was ignorant that Napier had been deceased for more than two years, addressed a letter to him, dated 28th of July 1619 (prefixed as a dedication to his *Ephemerides* for the year 1620), in which he expresses his high admiration of the *Canon Mirificus*, and his astonishment and delight on first becoming acquainted with the importance of Napier's great discovery. In the archiepiscopal library of Lambeth the original of a letter still exists, addressed by Baron Napier to Anthony Bacon in 1596, entitled "Secret Inventions necessary in those days for the Defence of this Island, and withstanding Strangers, Enemies to God's Truth and Religion." These inventions consisted of burning mirrors designed to fire the enemies' ships at a distance, by reflecting the sun's rays, or "the beams of any material fire or flame," to a focus. It does not appear that the invention attracted much notice at the time, owing probably to the modesty or humanity of the author, who, in relation to this matter, remarked on his death-bed, that the instruments of human destruction "should never be increased by any new conceit of his."

Baron Napier's last work was his *Rabdology and Promptuary*, published in 1617, and dedicated to the Chancellor Seton. He died at Merchiston on the 4th of April of the same year, in the sixty-eighth year of his age.

Napier was twice married. By his first wife, who was a daughter of Sir James Stirling of Keir, he had only one son,

VOL. XV.

named Archibald. He was appointed a privy councillor by James VI., under whose reign he also held the offices of treasurer-depute, justice-clerk, and senator of the college of justice; and by Charles I. he was raised to the peerage. By his second wife, a daughter of Sir James Chisholm of Cromlix, he had a numerous family of sons and daughters.

We have two Lives of the inventor of logarithms; one by the late Earl of Buchan, with an analysis of Napier's printed works by Dr Walter Minto, published in 1787; the other by Mr Mark Napier, advocate, published in 1834; both in 4to. (For additional information respecting this illustrious mathematician, see LOGARITHMS.) The following is a correct list of his different publications:—

1. A plaine Discouery of the whole Reuelation of Saint Iohn; set downe in two treatises: the one searching and prouing the true interpretation thereof; the other applying the same paraphrastically and historically to the text. Set forth by Iohn Napeir L. of Merchistoun younger. Edinburgh, printed by Robert Waldegrave, 1593, 4to. In republishing this work in 1611, the author subjoined "A resolution of certaine doubts, mooued by some well-affected brethren." The "fifth edition" was printed at Edinburgh, 1645, 4to. It was translated into French by George Thomson, and printed at Rochelle, 1602, in 4to. On the title, it is said to have been revised by the author himself ("reueue par lui-même"), and was reprinted in 1605, and again in 1607, in 8vo.

2. Mirifici Logarithmorum Canonis Descriptio, ejusque usus, in utraque Trigonometria, ut etiam in omni Logistica Mathematica amplissimi, &c., explicatio. Edinburgi, ex officina Andreæ Hart, 1614, 4to.

3. Rabbologie, seu Numerationis per Virgulas libri duo: cum Appendice de expeditissimo Multiplicationis Promptuario. Quibus accessit et Arithmeticae Localis liber unus. Edinburgi, excudebat Andreas Hart, 1617, 12mo. Reprinted at Lyons in 1626, and again in 1628, 12mo.

4. Mirifici Logarithmorum Canonis Constructio, et eorum ad naturales ipsorum numeros habitudines; una cum Appendice, de alia eaque præstantiore Logarithmorum specie condenda. Quibus accessere Propositiones ad triangula spherica faciliore calculo resolvenda, &c. Edinburgi, excudebat Andreas Hart, 1619, 4to. This posthumous work was published by the author's third son, Robert Napier. Some copies of it occur, along with the *Canonis Descriptio*, having a general title-page for both, dated 1619, the original title of 1614 being cancelled. Both works were reprinted at Lyons in 1620, 4to; and the first, followed with copious "Observations," was included in Baron Maseres's large collection, entitled *Scriptores Logarithmici*, vol. vi., London, 1807, 4to.

NAPIER'S RODS, or *Bones*, an instrument invented by Baron Napier, whereby the multiplication and division of large numbers is much facilitated. Suppose the common table of multiplication to be made upon a plate of metal, ivory, or pasteboard, and then conceive the several columns, standing downwards from the digits on the head, to be cut asunder; these are what are called *Napier's Rods of Multiplication*. But then there must be a good number of each; for as many times as any figure is in the multiplicand, so many rods of that species, or with that figure on the top of it, must we have, though six rods of each species will be sufficient for any example in common affairs. There must also be as many rods of 0's. But before we explain the mode of using these rods, there is another thing to be known, namely, that the figures on every rod are written in an order different from that in the table. Thus the little square space or division in which the several products of every column are written is divided into two parts by a line across from the upper angle on the right to the lower on the left; and if the product is a digit, it is set in the lower division; but if it has two places, the first is set in the lower, and the second in the upper division. The spaces on the top are not divided. There is also a rod of digits not divided, which is called the *index-rod*, and of this we require only one single rod.

Multiplication by Napier's Rods.—First lay down the index-rod; then on the right of it set a rod whose top is the figure in the highest place of the multiplicand; next to this again set the rod whose top is the next figure of the multiplicand, and so on in order to the first figure. Then the multiplicand is tabulated for all the nine digits; for in the same line of squares standing against every figure of the index-rod, we have the product of that figure; and therefore we have no more to do but to transfer the products and sum them. But in taking out these products from the rods, the order in which the figures stand obliges us to employ a very easy and small addition. Thus, begin to take out the figure in the lower part or units' place of the square of the first rod on the right, add the figure on the upper part of this rod to that in the lower part of the next, and

Napier
||
Naples.

so on, which may be done as fast as we can look on them. To make this practice as clear as possible, take the following example:—To multiply 4768 by 385. Having set the rods together for the number 4768 against 5 in the index, we find this number by adding, according to the rule 23840
Against 8, this number 38144
Against 3, this number 14304

Total product..... 1835680

To render the use of the rods yet more regular and easy, they are kept in a flat square box, the breadth of which is that of ten rods, and the length that of one rod, as thick as to contain six, or as many as may be required, the capacity of the box being divided into ten cells for the different species of rods. When the rods are put up in the box (each species in its own cell distinguished by the first figure of the rod set before it on the face of the box near the top), as much of every rod stands without the box as shows the first figure of that rod; also upon one of the flat sides without, and near the edge upon the left hand, the index-rod is fixed; and along the foot there is a small ledge, so that the rods when applied are laid upon this side, and supported by the ledge, which makes the practice very easy. But in case the multiplicand should have more than nine places, the upper face of the box may be made broader. Some make the rods with four different faces, and figures on each for different purposes.

Division by Napier's Rods.—First tabulate the divisor; then we have it multiplied by all the digits, out of which we may choose such convenient divisors as will be next less to the figures in the dividend, and write the index answering in the quotient, and so continually till the work is done. Thus 2179788 divided by 6123 gives in the quotient 356. Having tabulated the divisor 6123, we see that 6123 cannot be had in 2179; therefore take five places, and on the rods find a number that is equal or next less to 21797, which is 18369; that is, three times the divisor. Wherefore set 3 in the quotient, and subtract 18369 from the figures above, and there will remain 3428; to which add 8, the next figure of the dividend, and seek again on the rods for it, or the next less, which will be found to be five times; therefore set 5 in the quotient, and subtract 30615 from 34288, and there will remain 3673, to which add 8, the last figure in the dividend, and finding it to be just six times the divisor, set 6 in the quotient. Thus,

6123)2179788(356.

NAPIER, *Macvey*, descended from an ancient and respectable family in the west of Scotland, was born in 1776. He received his elementary education in the public school of his native parish; and subsequently studied in the Universities of Glasgow and Edinburgh, at both of which he attracted the favourable notice of some of the most distinguished professors. Being destined for the profession of the law, he was apprenticed to a member of the Society of Writers to the Signet. But the literary and philosophical studies to which he had early attached himself, withdrew his attention from the less interesting though more lucrative business of the law; and he speedily began to regard the latter as being, in his case at least, subsidiary only to his advancement in the former.

When yet very young, he was elected to the responsible situation of librarian to the Writers to the Signet. In this capacity Napier discovered an extensive knowledge of books, and a judicious discrimination in the selection of those best suited to the establishment over which he pre-

sided. At a subsequent period, the Writers to the Signet gave a marked proof of the increased estimation in which he was held, by selecting him for a lectureship on conveying, founded by the society, and shortly afterwards converted into a professorship in the university of Edinburgh. When the late Mr Constable purchased, in 1814, the copyright of the *Encyclopædia Britannica*, he at once fixed upon Napier as the individual best qualified to carry into effect the great improvements he projected in that publication. He was not disappointed in his expectations; and it is not going too far to say that the appearance of the *Supplement to the Encyclopædia Britannica*, edited by Napier, forms a memorable era in the history of British literature. Such was the confidence placed in the discretion and good taste of the editor, that the names of a host of individuals distinguished for learning, philosophy, and science are to be found among the contributors to this great work; which in consequence became the depository of a lengthened series of original and profound disquisitions in most departments of human knowledge.

The experience he had acquired in conducting the Supplement, his extended acquaintance with literature and literary men, and the confidence placed in him by the latter, naturally pointed Napier out as the proper, or rather as the only, person to undertake the task of editing a new edition of the *Encyclopædia* itself which should be worthy of the age and of the country. The misfortunes by which Mr Constable was unhappily overtaken made no change in this respect. The proposed edition was completed under its present publishers on the same scale on which it had been originally projected.

A vacancy in the situation of principal clerk of session having occurred some time after, when the Whig party came into power in 1830, Napier was appointed to the vacant place; and on receiving this appointment, he resigned his office of librarian.

Mr Napier had for a lengthened period been an occasional contributor to the *Edinburgh Review*; and on the appointment of Jeffrey to be dean of the Faculty of Advocates in 1829, he succeeded him as editor. Though he wrote little himself, his contributions are remarkable for ability, research, and perspicuity of statement; and he commanded in a high degree the confidence and esteem of those whose assistance was most necessary to sustain and extend the reputation of the leading Whig journal. Those who knew Napier only through the works he edited, or even through his lectures, could form no just idea of the man. He was at once a firm, an intelligent, and an honest friend.

For many years previously to his death, his health was very indifferent, and he occasionally suffered much. But his habitual cheerfulness never forsook him; and he continued to the last in the full enjoyment of his intellectual powers and of the society of his friends. He died in his seventy-first year, on the 11th February 1847.

N A P L E S.

NAPLES (Italian *Napoli*, Greek *Νεάπολις*, Latin *Neapolis*, German *Neapel*), the capital of the kingdom of the Two Sicilies, and the largest and most populous city in Italy, disputes with Constantinople the claim of occupying the most beautiful site in Europe. It is situated on the northern shore of the ancient *Crater* or *Sinus Cumanus*, now called from it the Bay of Naples, in 40. 52. N. Lat., and 14. 15. 45. E. Long., as taken from the lighthouse on the mole.

No other spot in the world combines within the same

compass so much natural beauty with so many objects of interest to the antiquary, the historian, and the geologist, as the Bay of Naples. Its circuit from the Capo di Miseno, on the N.W., to the Punta della Campanella, on the S.E., is about 35 miles, and is more than 52 miles if the island of Ischia, at the N.W., and the island of Capri, at the S. entrance, be included. At its opening between these two islands it is 14 miles broad; and from the opening to its head at Portici it is 15 miles deep. It affords good anchorage, with nearly 7 fathoms water, and is well shel-

Naples.

Naples. tered, except from winds which blow from any point between S.E. and S.W. There is a perceptible tide of nearly 9 inches.

On the N.E. shore of the bay, E. of Naples, is an extensive flat, forming part of the great plain of ancient *Campania Felix*, and watered by the small stream Sebeto and by the Sarno, which formerly flowed by Pompeii. From amidst this flat, between the sea and the range of the Apennines, rises Vesuvius, one of the most active volcanoes in the world, at the W. base of which, on the sea-shore, are the town-like villages of San Giovanni Teduccio, Portici, Resina, Torre del Greco, Torre dell' Annunziata, &c., and the classic sites of Herculaneum and Pompeii. At the S.E. extremity of the plain, 3 miles beyond the outlet of the Sarno, a great offshoot of the Apennines, branching from their main ridge near Cava, and projecting more than 12 miles due W. into a peninsular form, divides the Bay of Naples from the Bay of Salerno (*Sinus Pæstanus*), and ends in the bold promontory of the Punta della Campanella (the *Promontorium Minervæ* of the ancients), which is divided by a strait of 4 miles from the island of Capri. On the N. slope of this peninsular offshoot, where the plain ends and the coast abruptly bends to the W., stands the town of Castellammare, near the site of *Stabiæ*, at the foot of Mount Santangelo, which rises suddenly from the sea to a height of 4722 feet. On the same N. slope, but further W., and nearly opposite to Naples across the bay, are Vico, Meta, Sorrento, Massa, and many other villages.

The N.W. shore of the bay, to the W. of Naples, is more broken and irregular. The promontory of Posillipo, which projects due S., divides this part of the bay into two smaller bays—the eastern, in which is Naples; and the western, or Bay of Baïæ, which is sheltered from all winds. Beyond Posillipo is the small island of Nisida (*Nesis*); and at a short distance inland are the extinct craters of Solfatara and Astroni, and the Lake of Agnano. Further W., on a tongue of land, stands Pozzuoli (the ancient *Puteoli*); and beyond it, round the Bay of Baïæ, are Monte Nuovo, a hill thrown up in a single night in September 1538; the classic site of Baïæ; the Lucrine Lake; Lake Avernus; the Lake of Fusaro, or *Acherusia Palus*; the Elysian Fields; and the port and promontory of Misenum. Still farther to the S.W. stand the islands of Procida (*Prochyta*), and Ischia (*Pithecura* or *Inarime*), which divide the Bay of Naples from the extensive Bay of Gaeta.

Some of the local antiquaries, especially the learned Mazzocchi and Martorelli, on the evidence of etymological derivations, ascribe a Phœnician origin to Naples. All ancient writers, however, agree in representing it as a Greek settlement, though its foundation is obscurely and differently narrated. It seems that it was originally founded by a colony from the neighbouring Greek town of Cumæ, who gave it the name of *Parthenope*, from a legendary connection of the locality with the siren Parthenope, whose tomb was still shown at the time of Strabo. A number of Chalcidic and Athenian colonists seem to have afterwards joined the original settlers, and to have built for themselves separate dwellings, which they called *Neapolis*, or the new city, in contradistinction to the old settlement, which in consequence was styled *Palæopolis*, or the old city. All modern attempts to define the respective extent and situation of Palæopolis and Neapolis have utterly failed; but Livy's testimony leaves no doubt that they were close to each other, and identical in language and government.

In the year 328 B.C. the Palæopolitans having provoked the hostility of Rome by their incursions upon her Campanian allies, the consul Publius Philo marched against them, and having taken his position between the old and the new city, laid regular siege to Palæopolis. By the aid of a strong Samnite garrison which they received, the Palæopolitans were long able to withstand the attacks of the

consul; but at length the city was betrayed into the hands of the Romans by two of her citizens. Neapolis possibly surrendered to the consul without any resistance, as it was received on favourable terms, had its liberties secured by a treaty, and obtained the chief authority, which previously seems to have been enjoyed by the older city. From that time Palæopolis totally disappeared from history, and Neapolis became as an allied city—*fœderata civitas*—a dependency of Rome, to whose alliance it remained constantly faithful, even under most trying circumstances. In 280 B.C. Pyrrhus unsuccessfully attacked its walls; and in the second Punic war Hannibal was by their strength deterred from attempting to make himself master of the town. During the civil wars of Marius and Sylla, a body of partizans of the latter having entered it by treachery, 82 B.C., made a general massacre of the inhabitants; but Neapolis soon recovered the blow, as it was again a flourishing city in the time of Cicero. It became a *municipium* after the passing of the *Lex Julia*; under the Empire it is noticed as a *colonia*, but the time when it first obtained that rank is uncertain—possibly under Claudius.

Though a municipal town, Neapolis retained long its Greek culture and institutions; and even at the time of Strabo had gymnasia and quinquennial games, and was divided into *phratrîæ*, after the Greek fashion. When the Romans became masters of the world, many of their upper classes, both before the close of the republic, and under the empire, from a love of Greek manners and literature, or from indolent and effeminate habits, resorted to Neapolis, either for education and the cultivation of gymnastic exercises, or for the enjoyment of music and of a soft and luxurious climate. Hence we find Neapolis variously styled—by Horace as "*otiosa Neapolis*," by Martial as "*docta Parthenope*," by Ovid as "*in otia natam Parthenopen*." It was the favourite residence of many of the emperors. Nero made his first appearance on the stage in one of its theatres, Titus assumed the office of its Archon, and Hadrian became its demarch. It was chiefly at Neapolis that Virgil composed his *Georgics*; and after his death his remains were transferred and buried on the Hill of Pausilypus, the modern *Posillipo*, in its neighbourhood. It was also the favourite residence of the poets Statius and Silius Italicus, the former of whom was by birth a Neapolitan.

After the fall of the Roman Empire, Neapolis suffered severely during the Gothic wars. Having espoused the Gothic cause in the year 536, it was taken, after a protracted siege, by Belisarius, who, having turned aside an aqueduct, marched by surprise into the city through its channel, and put many of the inhabitants to the sword. In 542 Totila besieged it and compelled it to surrender; but being soon after recovered by Narses, it remained long a dependency of the Exarchate of Ravenna, under the immediate government of a duke, appointed by the Byzantine emperors. The Longobard invasion of Italy, and their subsequent conquests in Southern Italy, greatly narrowed the limits of the Neapolitan duchy. In the beginning of the eighth century, at the time of the Iconoclastic controversy, the Emperor Leo Isauricus having forced compliance to his edict against the worshipping of images, the Neapolitans, encouraged by Pope Gregory III., threw off their allegiance to the Eastern emperors, and established a republican form of government under a duke of their own appointment. Under this *régime* Neapolis retained her independence for nearly 400 years, though constantly struggling against the powerful Longobard Dukes of Benevento, who twice unsuccessfully besieged it. In 1027, however, Pandolfo IV., a Longobard Prince of Capua, succeeded in making himself master of it; but was expelled in 1030 by Duke Sergio, chiefly through the aid of a few Norman adventurers. In reward for their services, and as a security for their constant support, Sergio gave these Normans some land be-

Naples.

Naples.

tween Naples and Capua, on which they built the town of Aversa. Many other Normans soon poured south under the guidance of the sons of Tancred of Hauteville; and having eventually conquered the whole of South Italy and the island of Sicily from the Longobards, the Saracens, and the Greeks, Roger, a son of the great Count of Sicily, attacked Neapolis in 1130, and after a long siege, having compelled it to surrender, founded the present kingdom of Sicily and Naples. The history of Naples became ever since identified with the history of the kingdom, and will be given in this work under the head, SICILIES, *Two*.

Of ancient Neapolis there are few vestiges extant; all its buildings having gradually been changed and modernized. Two arches of an ancient theatre, in the street Anticaglia; two columns and other fragments of the temple of Castor and Pollux, preserved in the façade of the church of S. Paolo, a few arches of the Julian aqueduct, constructed by Augustus, which are called *Ponti Rossi*; and the extensive catacombs on the flanks of the hill of Capodimonte, are almost the only remains of its classic times.

The modern town is built at the base and on the slope of a range of volcanic hills; and, rising from the shore like an amphitheatre, is most advantageously seen from the water. A transverse ridge, branching from the steep hill crowned by the castle of St Elmo, and descending south to the shore, where it forms the promontory of Pizzofalcone, divides the town into two natural crescents; of which the one to the east includes within its circuit the largest and oldest part of the city—the ports, the arsenal, and the principal churches, palaces, and public establishments, and is traversed from north to south by a street two miles long, the lower part of which is called Toledo. The western crescent, known as the Chiaia, is a long and narrow strip between the sea and the hill of Vomero, and is the fashionable quarter of the town, where are the principal hotels, and where foreigners chiefly reside. The Riviera di Chiaia, a broad street, a mile and a-half long, bordered on the north by fine houses, and on the south by the public gardens, called Villa Reale, and by the sea, runs along this crescent from east to west, and ends in the quarters of Mergellina and Piedigrotta, at the foot of the hill of Posillipo. The ridge between these two crescents, or the Pizzofalcone, is chiefly the residence of the Neapolitan aristocracy. The eastern and western crescents are connected by a broad street or quay, which runs along the shore at the base of Pizzofalcone from the royal palace to the Villa Reale. The length of the town along the shore is 4 miles, and its breadth, from the Capodimonte to the Castel dell' Ovo, is $2\frac{1}{2}$ miles.

The streets are all well paved with lava or volcanic basalt, but, with the exception of the Toledo, the Riviera di Chiaia, the Largo delle Pigne, and the Molo, have no side footpaths. They were first lighted at night in 1806 with oil lamps, which in 1840 were superseded by gas in the principal streets. Many of the streets, especially in the old part of the town, are irregular and narrow, and, from the height of the houses, have a gloomy aspect. They are tolerably clean, filth being carried into the sea by a well-arranged system of sewers. The houses are more remarkable for their size than for their taste or elegance. They are mostly five or six storeys high, are covered with plaster made of a kind of pozzuolana, which hardens by exposure to the atmosphere, and have large balconies and flat roofs, which are frequently ornamented with flowers, shrubs, and small trees, planted in boxes filled with earth.

The city is defended by four castles—the castle of St Elmo, built on a steep hill commanding both crescents by King Robert the Wise, in 1343; the Castel dell' Ovo, so called from its oval shape, erected in 1154 by William I., on a small island which Pliny calls *Megaritis*, and which is now joined to the shore at the foot of Pizzofalcone by a causeway on arches 800 feet long; the Castel Nuovo, built

Naples.

near the harbour in 1283, from the designs of Giovanni Pisano, by Charles I. of Anjou, whose residence it was for some time; it is very picturesque, and contains, between two of its old round towers, the triumphal arch erected in 1470 to Alfonso of Aragon—the Castel del Carmine, founded near the east end of the town in 1484 by Ferdinand I. of Aragon. There are two ports—the Porto Grande and the Porto Militare. The former was begun in 1302 by Charles II. of Anjou, and completed in 1740 by Charles III. by the carrying out of an arm to the N.E. In its deepest parts it has from three to four fathoms water, and is protected from all winds; but a S.W. gale makes its entrance difficult. At its extremity there is a lighthouse, reduced to its present form in 1843. West of this port is the Porto Militare, begun in 1826, and finished by the present king. It is intended exclusively for Neapolitan ships of war, and has a depth of about five fathoms.

Naples has more than 300 churches, most of which are more remarkable for the richness of their internal decorations than for real architectural beauty. The most important of them is the cathedral or *Duomo*, which stands on the site of two temples, dedicated to Neptune and Apollo. The present building was begun in 1272 from the designs of Masuccio I., and dedicated to the Virgin of the Assumption, but was not completed till 1316. It contains several granite columns, taken from the original temples on the site of which it stands; but is an incongruous mixture of different styles of architecture. This is mainly owing to the numerous restorations of the building, caused by its repeatedly suffering from earthquakes. The interior consists of a nave and two aisles, separated by pilasters, to which are affixed columns of Egyptian granite, Cipollino and Africano, taken from the ancient temples of Neptune and Apollo. The baptismal font, on the left of the principal entrance, is an ancient vase of Egyptian basalt, adorned with Bacchanalian emblems in relief. Under the high altar is a subterranean chapel, supported by Ionic columns, and containing the tomb of San Gennaro, the patron saint of Naples; near which is a kneeling statue of Cardinal Carafa, attributed to Michael Angelo. Within the cathedral there are many chapels, the most remarkable of which is the Cappella del Tesoro, built in consequence of a vow made by the citizens during the plague of 1527, and dedicated to San Gennaro. It was begun in 1608, and completed after twenty-nine years. The entrance to it is through a magnificent bronze door. The interior is in the form of a Greek cross, and has seven altars, with pictures by Domenichino and Spagnoletto, and forty-two columns of brocatello, with niches containing nineteen bronze colossal statues of saints. In a silver tabernacle behind the high altar are preserved the two phials containing the blood of San Gennaro, supposed to have been collected by a lady during his martyrdom. The ceremony of the liquefaction of this blood takes place twice a year, in May and in September. If it liquefy quickly, the joy exhibited by the lower classes is great; but if there be any delay beyond the expected time, the tears, prayers, and cries are even greater, as the non-performance of the miracle is supposed to announce some dreadful impending calamity. Attached to the cathedral is the extensive palace of the Archbishop of Naples, who is always a cardinal. The other more important churches, both for architecture and for the monuments and paintings they contain, are—Santa Chiara, San Domenico Maggiore, San Filippo Neri, San Francesco di Paola, opposite the royal palace, the Gesù Nuovo, San Giovanni a Carbonara, the Incoronata, San Lorenzo, Santa Maria del Carmine, Santa Maria la Nova, Santa Maria della Pietà de' Sangri, San Martino, Montoliveto, and San Severino.

The royal palace, begun in 1600 by the viceroy Count de Lemos, from the designs of Domenico Fontana, partly destroyed by fire in 1837, and since repaired and greatly

Naples. enlarged by the present king, is an enormous building, with a front 448 feet long and 95 feet high, exhibiting the Doric, Ionic, and Composite orders in its three storeys. It stands on the N.E. side of a large square, which takes its name from it, is connected with the theatre of San Carlo, the arsenal, and the Castel Nuovo, and commands a most lovely view of the Bay, Vesuvius, and the Apennines. The reception apartments contain a fine collection of pictures by the best Italian masters. In the chapel attached to it there is an altar of lapis lazuli, agate, and many precious marbles. Adjoining the private apartments of the king there is his private library, which is very large, and contains a most valuable collection of prints and original drawings.

The private palaces most remarkable, either for their architecture or for the objects of art which they contain, are,—the general post-office, formerly Palazzo Gravina; the palaces Berio, Cavalcanti, Maddaloni, Forquet, formerly Stigliano, and Angri, in the street of Toledo; the Mari-gliano and Santangelo, formerly Carafa, in the street St Biagio de' Librai—the latter of which contains the largest private numismatic collection in Italy; the Cellammare, the Davalos, the Bisignano, the Fondi, and many others.

Hospitals and charitable institutions for relieving distress are very numerous, and generally well endowed. The most remarkable are—the Casa Santa degl' Incurabili, founded in 1521 by a lady, and enriched in later times by numerous benefactors. Its vast revenue is administered by a board appointed by the king. It is open to persons of both sexes and of every rank, and sometimes contains about 2000 in-patients, besides those that are sent to its convalescent branches in the suburbs of the city,—namely, the Ospedale de' Pellegrini, for the sick and wounded of all classes; and the Albergo de' Poveri, a magnificent building, one-third of a mile long, begun in 1751 by Charles III., as an asylum for orphans and for children whose parents cannot afford to give them an education. With several small institutions, which are its dependencies, it contains nearly 5000 inmates of both sexes, of whom some are taught the elementary branches of education, and music and drawing; whilst others are brought up to trades. Many of the boys brought up in it are sent into the army.

Naples abounds in theatres. The Teatro Reale di San Carlo is the largest and most splendid opera-house in Europe. It was erected by order of Charles III., by the architect Carasale, and first opened to the public in 1737. Having been accidentally burnt down in 1816, it rose from its ashes in seven months, under the direction of the architect Nicolini. It has six rows of boxes, 32 in each row, a pit capable of holding more than a thousand spectators, and a very spacious stage. Adjoining it are the concert and ball-rooms of the Academia Reale, the most select and aristocratic club in Italy, to which foreigners obtain admission through their minister. The Teatro Reale del Fondo is another opera-house, smaller than San Carlo, but very elegant. The Teatro Nuovo and Della Fenice are also smaller opera-houses, chiefly for the opera buffa. The Teatro de' Fiorentini is devoted to the Italian drama, and is very popular. The Teatro di San Carlino, though very small, is much frequented by all classes, and the performances are always in the Neapolitan dialect.

Scientific and literary institutions are also very numerous,—a university, a royal society, a botanic garden, an observatory, a Chinese college, a college of music, &c., &c. The university, which was founded by the Emperor Frederic II. in the thirteenth century, is under the direction of a president, assisted by a rector and a secretary-general, and has fifty-four different professorships. Admission to the lectures is free. A library, and cabinets of the various branches of natural history, are attached to it. The Chinese college was founded in 1732 by the celebrated Father

Naples. Ripa for the education of young Chinese, who are afterwards sent back to China as missionaries. The Royal Society meets once a year, and is divided into three branches,—the Accademia delle Scienze, of thirty members; the Accademia Ercolanese di Archeologia, of twenty members; the Accademia di Belle Arti, of ten members. Each branch has a triennial president, a perpetual secretary, and meets twice a month. The observatory, which is situated on the hill of Capodimonte, and commands a magnificent view, was finished in 1820 on the plan of the celebrated Father Piazzzi. The College of Music, which is of European celebrity, is under royal direction, and supplies gratuitous instruction to 100 pupils.

But of all public institutions at Naples the Museo Borbonico, called also the *Studi*, is by far the most important and interesting. The building was begun in 1586 for cavalry barracks, but was remodelled in 1615, and adapted for the university. It was enlarged and reduced to its present form in 1790, and converted into a royal museum, which, besides the Farnese collection inherited by the Bourbons of Naples, has been since so far enriched by the objects found in Herculaneum, Pompeii, Stabiae, Puteoli, Capua, Nola, Nuceria, Pæstum, &c., that it may now be considered as the finest in Europe, and quite unique with respect to Grecian and Roman antiquities. It is divided into seventeen collections, which are arranged as follows:—

On the ground floor,—1. Ancient frescoes, found chiefly at Herculaneum and Pompeii. There are more than 1600 objects, and there is a daily increase from the progress of the excavations. Among them are large historical pictures, wonderfully well executed, and admirable with respect both to accuracy of outline and beauty of composition. 2. Mosaics and mural inscriptions. 3. Egyptian antiquities. 4. Ancient sculptures, a large and most interesting collection;—the “Wounded Gladiator,” “Ganymede and the Eagle,” the “Farnese Minerva,” a sitting statue of Agrippina, the “Flora Farnese,” the “Aristides,” and the “Psyche,” being some of its numerous gems. 5. Inscriptions. Here are placed the “Ercole Farnese,” and the celebrated group of the “Toro Farnese,” described by Pliny as one of the most remarkable monuments of antiquity. It was the joint work of the Rhodian sculptors Apollonius and Tauriscus, who cut it from a single block of marble; and it was brought from Rhodes to Rome, where it was found much injured in the Baths of Caracalla. It represents Zethus and Amphion tying Dirce by the hair of her head to the horns of a bull, in revenge for her seducing the affection of their father Lycus, King of Thebes, from their mother Antiope, who interposes in favour of her rival. It was brought to Naples in 1786, and placed in the Villa Reale, whence it was removed to its present place. 6. Gallery of bronzes, the most extensive collection of the kind in the world. A “Drunken Faun,” “Mercury in Repose,” the “Sleeping Faun,” and the “Dancing Faun,” are generally considered the finest bronze statues in the world.

On the staircase,—7. A collection of more than 4000 specimens of ancient glass, showing the skill the Romans had attained in this manufacture. 8. A collection of upwards of 5000 articles of pottery. 9. Cinquecento objects. 10. A reserved cabinet, admission to which is difficult. It contains several Venuses, among which is the “Venus Callipyge,” the rival of the “Venus de Medicis.” It is attributed to Praxiteles, and was found among the ruins of the Golden House of Nero.

Upstairs,—11. A collection of 1750 papyri, most of them discovered in the year 1752 in a suburban villa at Herculaneum. The scrolls of papyri are so precisely like charcoal that the workmen destroyed those that had at first been met with; but on a room being opened, in which the scrolls were ranged in presses round the walls, this remarkable arrangement excited curiosity, and led to the discovery of

Napoleon.

Greek and Latin words on these supposed pieces of charcoal. Seven inkstands, with a stylus in its case, were found in the same apartment. After several unsuccessful attempts at unrolling these papyri, Padre Piaggi at length invented an ingenious machine for separating and unrolling them, which, though slow and tedious, is still in use as the best that has been suggested. Those hitherto unrolled are 500 in number. Two volumes of them were published, the first in 1793, and the second in 1809; a third volume has long been preparing for the press. No known work has yet been discovered; and, so far as the examination has advanced, the collection seems to consist of treatises on the Epicurean philosophy, on music, and on rhetoric. It is conjectured, that of the MSS. still unrolled twenty-four are in Latin and the remainder in Greek. 12. Cabinet of gems and cameos. 13. A collection of about 40,000 medals and coins, chiefly of Magna Græcia and Sicily. 14. Seven rooms of small bronzes, which bring before us the manners, habits, and every-day life of the inhabitants of Pompeii. 15. A collection of upwards of 3000 Greek and Etruscan vases, comprising the finest specimens existing. 16. An extensive gallery of paintings, containing some of the finest pictures of the best Italian masters. 17. The public library, called the *Biblioteca Borbonica*. It contains 4000 MSS., and 200,000 printed books, of which 6000 are works printed in the fifteenth century. Among the MSS. there are many of great rarity and importance. We shall only mention the celebrated *Uffizio Farnese*, written by Montorchi, and illustrated by Giulio Clovio, which is considered the gem of illuminated works.

As there is not a museum in any country which in all respects can be compared with this, and as it forms the chief object of curiosity in the city, we have thought it advisable to give a faint idea of its contents. Access may always be had to it from nine in the morning to two in the afternoon, on all but festival and gala days.

The other public libraries in Naples are the *Branconiana*, with more than 70,000 printed books, and about 7000 manuscripts; the *Biblioteca dell' Università*, with 28,000 printed volumes; and the *Biblioteca de Girolomini*, with 18,000 printed books, and 60 manuscripts. There are besides many large private libraries.

Naples is abundantly supplied with vegetables, fruit, and all kinds of provisions from the fertile fields in the vicinity. The average prices of the chief articles of sustenance are,—bread and flour, 2d. per lb., beef 5d., mutton 3d., pork 2d., cheese 6d., butter 1s. 4d., &c. The fishing in the neighbouring water gives occupation to a large portion of the male population, and supplies abundance of food. Macaroni, vermicelli, and other varieties of paste prepared from the wheat brought from Apulia, which is distinguished by its hardness, form a very common kind of sustenance with the Neapolitan people. A notice of the imports and exports of Naples, in which city most of the foreign trade of the continental part of the kingdom is carried on, will be found under SICILIES, Two.

The climate of Naples is, upon the whole, salubrious and mild; but in February and March is subject to cold and

sharp winds, rendered more trying to weak lungs by the heat of an always powerful sun. It is well suited for invalids labouring under general debility and deranged health, or nervous dyspepsia; but it is questionable whether it is suited as a winter residence for consumptive patients. For the latter class of invalids the local physicians recommend those parts of the city which are removed from the sea, and have a less irritating and more constant atmosphere. The city is well supplied with water, but not all of equally good quality; the water especially with which the quarter of Chiaia is supplied, having often at first a tendency to produce dysentery in strangers, who would do well to see that they get the *Acqua del Leone*, a pure spring in the *Mergellina*. There are two mineral springs of great local celebrity,—the *Acqua Sulfurea*, containing sulphuretted hydrogen and carbonic acid gas, and the *Acqua Ferrata*, a chalybeate spring, largely impregnated with carbonic acid and iron. They rise on the sea-shore at the foot of *Pizzofalcone*, at a short distance from each other.

The population of Naples has of late years been steadily increasing, notwithstanding two severe visitations of cholera. In 1830 it was 358,550; on the 1st January 1851 it was 416,475. There were in the latter year 3651 marriages; 14,991 births, of whom 7606 were males, and 7385 females; 1977 foundlings; and 124 illegitimate children. In the same year there had been 15,015 deaths, a number above the average mortality, which, on a calculation of ten years, gives an excess of nearly 1100 births per annum. On the 1st January 1857 the population had increased to 419,850. These numbers include a garrison of about 20,000 men, but do not include strangers, of whom there is always a considerable number at Naples, especially in the winter months.

At Capodimonte, which is a suburb on the N. of the city, there is a magnificent palace, begun by Charles III., and finished by the present king. It is surrounded by a large park, and contains a fine gallery of modern paintings, chiefly by Neapolitan artists. Another large royal palace is at Portici, 4 miles S.E. of Naples. At the W. extremity of the city, where the Riviera di Chiaia terminates, is the Grotta di Pozzuoli, a tunnel 2244 feet long, 21½ feet wide, and varying from 69 to 25 feet in height. It was excavated in classic times through the hill of Posillipo, in the old volcanic tufa, and in the fifteenth century enlarged by Alfonso I. of Aragon. It opens a direct communication between Naples and Pozzuoli.

Numerous and most interesting excursions can be made in the environs of the city. Pozzuoli, the Lake of Agnano, and the Grotta del Cane, Lake Avernus, the Lucrine Lake, Baia, the ruins of Cumæ, Misenum, the islands of Procida, Ischia, and Capri, the remains of the vast amphitheatre of Capua, the splendid royal palace of Caserta, Beneventum, Vesuvius, Herculaneum, Pompeii, Stabiae, Castellammare, Sorrento, Amalfi, Salerno, Pæstum, &c., are all within a short distance of Naples, and contribute to its attractions as a winter, or even summer residence for strangers. Caserta, Capua, and Castellammare are easily reached by railway. Two railways are to connect Brindisi and Rome. (***)

N A P O L E O N.

NAPOLÉON BUONAPARTE, or BONAPARTE, was born at Ajaccio, in Corsica, on the 15th of August, 1769. He was descended from a patrician family, which had been of some note in Italy during the middle ages; and one of his ancestors, the gonfaloniere Buonaparte of San Nicolo, had governed the republic of Florence about the middle of the thirteenth century. His father, Carlo Buonaparte, was an advocate of considerable reputation; and his mother, Letizia Ramolini, was eminent alike for personal beauty and

uncommon strength of character. When the Corsicans under Paoli rose in arms to assert their liberty against the pretensions of France, Carlo Buonaparte espoused the popular side; and through all the toils and dangers of his mountain campaigns was attended by his lovely and high-spirited wife. Upon the termination of the war, the father of Napoleon meditated accompanying Paoli into exile; but his relations dissuaded him from taking this step; and being afterwards reconciled to the conquering party, he was pro-

Napoleon.

Napoleon. tected and patronized by the Comte de Marbœuf, the French governor of Corsica. Napoleon was the second child of his parents—Joseph, afterwards King of Spain, being the eldest born; but he had three younger brothers, Lucien, Louis, and Jerome; and three sisters, Eliza, Caroline, and Pauline. Five others appear to have died in infancy; and at the age of thirty Letizia became a widow by the death of her husband, who seems to have left his family but indifferently provided for.

In his early years Napoleon betrayed no marked singularity; and when his character began to be formed, its development was too profound and too essentially intellectual to attract the notice of ordinary observers. At the age of ten he was admitted to the Military School of Brienne, where he spent several years devoted to his studies, and afterwards removed to a similar institution at Paris, where he appears to have completed his education. That he laboured hard both at Brienne and at Paris, may be judged from the vast quantity of information which his strong memory ever placed at his disposal, and which, from the nature of his after life, must have been nearly, if not wholly, accumulated at this period. He succeeded in all that he undertook, because his will was resolute and his perseverance indomitable. He applied himself particularly to the study of mathematics, and made good progress in history and geography, but neglected Latin and the *belles lettres*. His intellectual faculties exerted themselves without any great effort on his part. He had a lively and prompt conception, a strong memory, and a cool and decided judgment. A foreigner, poor and proud, he kept aloof, for the most part, from the other boys, who were accustomed to taunt the distant young Corsican. He commonly sought for something to interest him; and this disposition placed him in a species of solitude, where he communed only with his own thoughts—a state which afterwards became habitual to him in all situations through life.

His birth having destined him for service, Napoleon had just completed his sixteenth year, when, in August 1785, after being examined by Laplace, he obtained his first commission as lieutenant of artillery in the regiment of *La Fère*. Never did he receive any title with so much pleasure as this. He was delighted beyond measure at his promotion; and the highest pitch to which his ambition then aspired was, that he might one day wear a couple of *epaulettes à bouillons*. A general of artillery seemed to him the *ne plus ultra* of human grandeur. He was already desirous of fame, however, and had conceived the idea of making himself a name by writing the history of the war in Corsica. He communicated his intention to Paoli, at the same time requesting that that officer would furnish him with the necessary information; but an historian of eighteen did not probably inspire any great confidence, and Paoli took no notice of his proposal. His advancement, however, indemnified him for this little mortification. In the year 1789 he obtained a company of artillery; and the Revolution, which broke out immediately afterwards, seemed to open up a new and more enlarged sphere of action. With this movement he soon foresaw that all his hopes and prospects were identified. "Had I been a general," said he, in the evening of his life, "I might have adhered to the King; but being a subaltern, I joined the patriots."

Happening to be in Paris in the year 1792, he witnessed the scene of the 20th June, when the revolutionary mob stormed the Tuileries, and placed the lives of the King and his family in the greatest jeopardy. He followed the crowd into the garden before the palace; and when Louis XVI. appeared on a balcony with the red cap on his head, he could no longer suppress his contempt and indignation.

"Poor driveller," said Napoleon; "how could he suffer this rabble to enter? If he had swept away five or six hundred of them with his cannon, the rest would soon have disappeared." He was also a witness of the events of the 10th of August, when the throne was overturned, a provisional council established, the king confined in the Temple, the Republic proclaimed, and a national convention called to frame a charter. At this time he was without employment, and poor; wandering idly about Paris, living at the shops of restaurateurs, projecting a variety of schemes,—some of them wild enough,—and in a great measure dependent upon the scanty resources of his class-fellow Bourrienne. But the circumstances of the times were such that he was not suffered to remain long inactive. Being offered the command of a battalion of national volunteers destined to join the expedition to Sardinia, he readily accepted it; and upon the return of the expedition he re-entered the artillery with the rank of superior officer, or commandant. Till the siege of Toulon, however, he led an insignificant life. But this operation proved in some measure decisive of his fortunes. He saw that, from the situation which he held, as second in command of the artillery, he might have some influence on the result of the siege; and the event justified his anticipations.

When, towards the close of August 1793, Toulon, the great port and arsenal of France on the Mediterranean, had, along with the fleet, been delivered into the hands of the allies, the situation of France was truly deplorable. Lyons had raised the standard of the Bourbons; civil war raged in Languedoc and Provence; the victorious Spanish army had passed the Pyrenees, and overrun Roussillon; and the Piedmontese army, having cleared the Alps, was at the gates of Chambery and Antibes. Terror, discord, and defection reigned within; whilst on the frontiers one reverse followed hard at the heels of another. But the allies were not sufficiently sensible of the importance of the acquisition which they had just made. About six weeks were passed in assembling the force and means necessary for the siege. On the 15th of October a council of war was assembled at Olioules, where the conventional pro-consul Gasparin presided; and on this occasion there was read to the council a memoir on the conduct of the siege of Toulon, which had been drawn up by the celebrated engineer D'Arcon, and approved by the committee of fortifications. Napoleon opposed the adoption of this plan, and proposed one much more simple. "Your object," said he, "is to make the English evacuate Toulon. Instead of attacking them in the town, which must involve a series of operations, and ruin the place, endeavour to establish batteries so as to sweep the harbour and roadstead. If you do this, the English ships must take their departure, and the English troops will certainly not remain behind them." He then pointed out a promontory nearly opposite the town, by establishing batteries on which the desired effect might be attained. "Gain La Grasse," said he, "and in two days Toulon will be yours." Had this suggestion been adopted in time the result would have been as Napoleon predicted; but the English had leisure allowed them to construct Fort Mulgrave, and to render it so strong that it went by the name of Little Gibraltar. Nevertheless, Napoleon's system prevailed. Instead of attacking the body of the place, the principal effort was directed against Fort Mulgrave; and in a month the desired end was obtained. On the 18th December the besiegers entered Toulon, but were able to save only the half of the squadron; the other half, the arsenal, and the dock-yards, having been consumed by the conflagration kindled by the English as they abandoned the place.¹

¹ During the siege of Toulon, Napoleon, whilst constructing a battery under the enemy's fire, had occasion to prepare an order, and called for some one who could write with facility. A young serjeant stepped out, and, leaning on the breast-work, wrote as he dictated.

Napoleon. The recovery of Toulon was a service of the very first importance to the revolutionary government. It suppressed the insurrectionary spirit in the south of France, restored the credit of the republican arms, and rendered disposable the force which had been employed in the siege. But the man to whose genius alone success was due did not immediately obtain the credit of this important achievement. The truth, however, was too generally known to be effectually concealed. Napoleon was appointed general of brigade, and in the beginning of 1794 was sent to the army of Italy to command the artillery. The general-in-chief, Dumerbion, was old and incapable; the head of his staff, though a man of information, wanted talents; and, between them, war was carried on without art or skill in the Maritime Alps. Napoleon proposed a plan for turning the famous position of Saorgio. His suggestion was adopted; Saorgio, with all its stores, surrendered, and the French obtained possession of the Maritime Alps. He then proposed another, which had for its object to unite the army of the Alps and that of Italy under the walls of Coni—an operation which would have secured Piedmont, and enabled the combined force, without any great effort, to establish itself on the Po. It was found impossible, however, to come to an arrangement with the staff of the army of the Alps; but Napoleon indemnified himself by carrying the army of Italy as far as Savona, and to the gates of Ceva; by which means he disengaged Genoa, then threatened by the allies, and would have achieved more important results had not his progress been stopped by the approach of winter and the imperative orders of the committee. He was superseded on the 6th of August 1794, apparently in consequence of the labours of Aubry, who had reformed the organization of the army, in order to impart to it greater solidity.

Before the end of the year he went to Paris in order to solicit employment, but at first experienced a very cold reception, probably on account of his supposed connection with Robespierre, with whose younger brother he was known to have lived on terms of friendship. The re-action consequent on the downfall of that extraordinary personage was then at its height, and threatened France with evils not less terrible than those from which it had just escaped. Everything was in an unsettled state, and the monthly renewal of the Committee of Public Safety served only to increase the confusion. After a time, however, Napoleon was placed amongst the generals of infantry appointed to serve in La Vendée; but he refused to act in a situation which he considered as altogether unsuitable to him, and resolved to remain at Paris, where he might be more usefully employed. This proved a fortunate determination, and soon led to service of a more congenial kind. Kellermann had just allowed himself to be beaten in the Apennines. The committee were anxious to repair the disaster, and with this view attached Napoleon to the board of military operations, with orders to prepare such instructions as might seem calculated to bring back victory to the national standards. This afforded him an opportunity of making his talents known, and probably contributed not a little to the future advancement of his fortunes. Soon afterwards, he was appointed to command a brigade of artillery in Holland, where for some time the war had languished; but before he could avail himself of this appointment, his services were required upon a nearer and more important field of action.

During the contest between the Convention and the sections of Paris (of which details will be found in the article

FRANCE) it was proposed to Napoleon to command, under Napoleon. Barras, the armed force destined to act against the Parisians. He consented, upon condition of being left free from all interference, and lost not a moment in sending to Meudon for the artillery. He had 5000 men and 40 pieces of cannon, a force more than sufficient to put down a riot, but not too much against a national guard well armed, and provided with artillery; and he was reinforced by 1500 patriots, organized in three battalions.

On the 13th of Vendemiaire (4th of October 1795), the sectionaries marched, nearly 30,000 strong, against the Convention. One of their columns, debouching in the Rue Saint-Honoré, advanced boldly to the attack; but it was instantly checked by the fire of the artillery, which swept the street with grapeshot, and soon afterwards it gave way in confusion. A number of the fugitives attempted to make a stand on the steps of the church of St Roche, where, owing to the narrowness of the street, they were in a great measure sheltered from the fire of the artillery. Napoleon, however, promptly brought a gun to bear upon them, and in a few minutes this crowd was dispersed, leaving behind them a number of dead. The column which debouched by the Port-Royal was not more fortunate. Exposed to the direct fire of the guns stationed below the Tuileries, and taken in flank by that of the other batteries by which the bridge was commanded, all its efforts to establish itself upon the quays of the Seine proved unavailing, and, after a very short struggle, it dispersed, and fled in all directions. In less than an hour the whole was ended, and the Convention victorious. This event, so trivial in itself, and which scarcely cost 200 men on each side, had important consequences. It prevented the revolution from retrograding; it enabled the Convention to disarm the sections; and, above all, it had a marked influence upon the future fortunes of Napoleon. The eminent service he had rendered was immediately rewarded with the rank of general of division; in five days he was named second in command of the army of the interior; and soon afterwards, on the resignation of Barras, he was advanced to the chief command. He had now passed into the order of marked and distinguished men. But the situation which he held was by no means suited to his views. He longed to make war upon a more extended theatre of action, and to profit by the advantages which fortune had thrown in his way.

It was at this time, when his residence in Paris had begun to appear insupportable to his active mind, that he became acquainted with the widow of General Beauharnais, whom he afterwards married. At the moment when the sections were disarmed, the sword of her husband, who had perished by the guillotine, a victim of the tyranny of Robespierre, had been taken from her; and she now sent her son Eugene, a boy of fifteen, to beg that it might be restored to her. Her request was at once complied with, and the boy shed tears as he received from the hands of Napoleon the sword of his unfortunate father. This scene touched Napoleon; and, having gone to give an account of it to the mother of Eugene, he was so enchanted with her elegance and grace, that he soon afterwards made her a tender of his hand, which was accepted. Such appears to be the simple truth in regard to the origin of his relations with Josephine, concerning which so many absurd and injurious stories have been circulated. Napoleon had little relish for the society of women, which accorded neither with his tastes nor his character, and in which he experienced constraint; but, being desirous to fix himself in life,

The writing was just finished, when a shot struck the ground by the side of the volunteer secretary, scattering dust over him and everything near him. "Good," said the serjeant, laughing; "we shall this time have no need of sand." The cool gaiety of the remark pleased Napoleon; he kept his eye on the man; and Junot—for it was he—rose in the sequel to the rank of a marshal of France, and was created Duke of Abrantes.

Napoleon. and finding in Josephine spirit and elegance united with celebrity, he resolved to make her his wife. The marriage took place on the 9th of March 1796, only a few days before he set out to assume the command of the army of Italy.

Tranquillity being now restored at Paris, the Directory had time to turn their attention to the state of affairs, particularly to that of the army of Italy, the condition of which was by no means satisfactory. It was determined to supersede Schérer, who had disappointed the expectations of the Directory, and to give it a new general; and as the chief command of the army of the interior naturally led to that of an active force, provided the individual holding it possessed the confidence of the government, Napoleon was consequently appointed general-in-chief of the army of Italy. To this command he had pre-eminent, and indeed exclusive claims. When serving under General Dumorbion, as commandant of artillery, he had turned the important position of Saorgio, and disengaged Genoa, then threatened by the allies; when employed at the board of military operations, he had digested a plan of campaign, the result of which was the signal victory gained at Loano, and the possession of the line of the Apennines, as far as Savona and the sources of the Bormida; and now, when brought into more direct contact with the government, he satisfied Carnot, to whom the direction of military operations was intrusted, that his plan in regard to Piedmont, which had been rejected by the Committee of Public Safety in 1794, might still be executed, with every prospect of success. These circumstances, independently of his services at Toulon, and also against the insurgent sections of Paris, naturally pointed him out as the person best qualified to obtain that success of which the Directory at this time stood so much in need, in order to support its credit and consolidate its power. That his talents were fully appreciated, and that he was solely indebted to his merits for this splendid command, admits of no doubt whatever. "Advance this young man," said Barras to one of his colleagues, "or he will advance himself without you." Napoleon quitted his wife ten days after their marriage, and, after a rapid journey, arrived at the head-quarters of the army at Nice. With that moment began the most brilliant scene of his entire career. "In three months," said he, "I shall be either at Milan or at Paris;" and before a year elapsed, he had grown old in victory.

The plan which he proposed for the campaign united all suffrages; for, though at once bold and original, it was in reality extremely simple. It had been agreed that he should manœuvre by his right, in order to descend by Montferrat upon Lombardy, directing all his efforts against the Austrians, in the hope of detaching Piedmont from the imperial alliance. The armies of Germany being re-organized, were to resume the offensive by the end of April, and to endeavour to pass the Rhine. Jourdan, who commanded 70,000 men on the Lower Rhine, was to blockade Mayence with 30,000, and to advance into Franconia with from 40,000 to 50,000. Moreau, who had nearly an equal number under him, was to mask Mannheim, and advance in Suabia; and it was proposed that both should unite in the heart of Bavaria. As to Napoleon, he had no other task to perform than that of advancing on the Adige; provided he succeeded by his victories in detaching Piedmont from the coalition, or in dethroning the King of Sardinia if the latter should refuse to make peace. In a word, this plan was merely a copy of that which Napoleon had previously drawn up for the committee, and the execution of which that body had recklessly intrusted to the incapable Schérer. Its distinctive characteristic consisted in the mode by which it was proposed to gain access to the fertile regions of Italy. Former invaders had uniformly penetrated the Alps at some point or other of that mighty range of moun-

tains. Napoleon judged that the same end might be more easily attained by turning them; that is, 'by advancing along the narrow gorge of comparatively level country which intervenes between these huge barriers and the Mediterranean, and by forcing a passage at that point where the last elevations of the Alps pass by gradual transition into the first and lowest of the Apennine range. The military advantages of operating in this direction will be immediately apparent.

Napoleon arrived at Nice on the 27th of March, and there found the army in a very precarious as well as destitute condition. Perched upon the summits of the Apennines, from Savona to Ormea, it was too widely dispersed, and its communications with France, running along the coast in a parallel direction between the enemy's line and the sea, were everywhere exposed; whilst the soldiers were in rags, without shoes, and a prey to almost every species of misery. Napoleon lost not a moment in placing the army in more advantageous positions, and in announcing that he was about to assume the offensive, with a view to provide for its wants, at the same time that he consulted its glory. This announcement had the desired effect. The soldiers forgot their privations, and eagerly longed to signalize their courage and devotion under the young chief who had promised to lead them to victory. Having occupied the principal roads leading from Nice to Italy, particularly that which sweeps the north by Saorgio, and crosses the chain of the Alps at the Col di Tende, Napoleon demanded of the senate of Genoa a free passage by the city and the Bochetta, along the road leading from Genoa to Alexandria, promising, in return, to carry the theatre of war beyond its frontiers, and to insure it the alliance and protection of the French republic.

On the 10th of April the Austrian general Beaulieu descended from the Apennines by the Bochetta, at the head of his left wing, and having dislodged the advanced guard of the French from Voltri, carried two of their redoubts. On the 12th Napoleon defeated the Austrian centre under Argenteau, overcame the Piedmontese on the 13th, and on the day following compelled Provera to lay down his arms. After a few more decisive encounters, in which he carried all before him, the conqueror concluded a sort of armistice at Cherasco, by which the King of Sardinia engaged to deliver up Coni, Alexandria, and Ceva, to withdraw from the coalition, and to send the Count de Ravel to Paris to treat of a definitive accommodation.

Thus, in somewhat less than a month, Napoleon with an army destitute of everything, had gained six victories, taken twenty-one standards, fifty guns, and several strong places, conquered the richest part of Piedmont, made 15,000 prisoners, and killed or wounded 10,000 men. He had reduced the Austrians to inaction, destroyed the army of the King of Sardinia, detached him from the imperial alliance, wrested from his hands the keys of the Alps, and established a solid basis for his future operations. In a few days he had done more than the former army of Italy in four campaigns; he had displayed consummate genius in achieving victory, and proved that he combined with it the still rarer talent of turning it to profit, by promptly gathering up its fruits. But his hopes were not yet realized. To deliver Italy from the German yoke, and to falsify the proverb which regarded that country as the tomb of the French, was the task which he still reserved for himself, and which he hesitated the less to undertake, as the armistice had left him at liberty to direct his whole force against the isolated army of Beaulieu, now too much enfeebled to resist his attacks with any chance of success.

No commander ever appreciated more justly than Napoleon the value of time in military operations. The day after the signature of the treaty of Cherasco, he put his divisions in motion, and directed them upon Alexandria.

Napoleon.

Partly by stratagem, and partly by dexterous movements, Napoleon succeeded in obliging Beaulieu to withdraw from his position at Valeggio, on the Ogogno, and to attempt concentrating his army towards Lodi. With the view of forcing the Austrians to retire from this position, Napoleon marched on Lodi, at the head of the grenadiers and the corps of Messena and Augereau, leaving before Pizzighetone a division to mask that place and cover his right, and taking measures for the safety of his left, by directing Serrurier upon Pavia. On the 10th he arrived before Lodi, where Beaulieu, having retired with the main body of his army to Crema, had left General Sebottendorf with 10,000 men to defend both sides of the Adda. By means of this strong rearguard the enemy had hoped to preserve the bridge of Lodi, which was defended by twenty pieces of cannon established on the left bank; but they soon found that they had reckoned without their host. A battalion and some squadrons which occupied the town of Lodi were, without much difficulty, dislodged, and the French reached the bridge before the enemy's workmen had time to cut it down. Napoleon instantly formed his grenadiers in close column, and rushed along the bridge. The troops advanced with loud shouts to the attack, but being assailed by a perfect storm of grape-shot, they hesitated for a moment, and began to waver. The generals, including Napoleon himself, hurried to the front, cheering and animating the men by their example. The effect was electric. The column dashed along the bridge in spite of the tempest of fire which thinned their ranks, overthrew all that opposed their progress, carried the enemy's batteries at the point of the bayonet, and dispersed his battalions.¹ Sebottendorf retreated upon Crema, with the loss of fifteen guns and 2000 men killed or wounded. This, though only an affair of the rearguard, was a daring feat of arms; and its immediate consequences were the occupation of Pizzighetone, the retreat of Beaulieu towards the Mincio, and the triumphal entry of Napoleon into Milan, where his presence had become absolutely necessary. As the French troops had been in continued motion for a month, it was judged expedient to allow them some days' rest; and hence Beaulieu was not pursued.

Having thus descended like a torrent from the Apennines, overthrown and dispersed all that opposed him, separated Piedmont from the coalition, received the submission of the Dukes of Parma and Modena, driven the Austrians behind the Mincio, and entered the capital of Lombardy in triumph, Napoleon immediately directed his attention to the internal administration of the country, prescribed the measures necessary for the reduction of the citadel of Milan, imposed contributions, and made arrangements for establishing the republican system in Italy. His career of victory had been one of unexampled rapidity, and he now sought to secure and consolidate the conquests he had made. The intelligence of his success, however, appears to have excited astonishment and suspicion in the minds of the French Directory, who perceived with alarm that their young general had already made himself master of Italy. Scarcely had he reached Milan, when he received orders to divide his army in two; to give up the command of that of Italy to Kellermann, who was to observe the Austrians on the Mincio; and with the remaining 25,000 men, forming an army of the south, to advance upon Rome, and even to act against Naples. But this division of force, at the moment when it was about to contend against all the resources of the House of Austria, was a great deal too absurd to be

Napoleon.

submitted to by a commander like Napoleon; he answered by resigning his command, and thus saved the army from inevitable destruction. Meanwhile, he resolved to drive Beaulieu into the Tyrol, and with this view he addressed to his soldiers one of the most remarkable proclamations that ever proceeded from his pen. He knew well the men with whom he had to deal; he knew that the French soldiery, full of fire and enthusiasm, would be transported by an appeal which awakened in their minds heroic sentiments; he knew that such an address would produce at Rome or at Naples the same effect as it had done at Turin; he knew also that in proportion as he exalted the courage of his troops he struck terror into those of the enemy, and at the same time bequeathed to posterity a monument of his talent for command. The revolt of Lombardy for a moment endangered the success of his plan. On the day when he quitted Milan to advance against the Austrians, the tocsin sounded in the rear of his army; the people flew to arms, and having seized upon Pavia, put the garrison to death. The least hesitation on his part would have rendered this rising general. Without stopping the march of the army, he proceeded in all haste to Pavia, followed by 300 horse and a battalion of grenadiers, at the head of which he forced the gates, penetrated into the city, which was delivered up to pillage, ordered the municipality to be shot, and thus, by one vigorous blow, extinguished the insurrection in its principal focus. At Benasco, Lannes acted with equal promptitude and severity; and at Lugo, where a squadron of French horse had been destroyed, a number of the male inhabitants were shot.

After the defeat of Lodi, Beaulieu had not ventured to halt behind the Oglio, nor even behind the Chiesa. He preferred the stronger line of the Mincio, flanked on the left by the fortress of Mantua, and on the right by the Lago di Garda and the mountains of the Tyrol. Behind this barrier he established his army, with his centre posted at Valleggio, his left at Goito, and his right at Peschiera, a small place belonging to the Venetians. As the wings thus rested upon two strong places, Napoleon resolved to force the centre; at the same time making demonstrations on the side of Peschiera, which covered the enemy's line of retreat to the Tyrol. On the 30th of May he arrived at Borghetto with the mass of his army, and immediately dislodged an advanced guard of the enemy stationed on the left of the Mincio. Having repaired the bridge of Borghetto, which the Austrians had partly destroyed in their retreat, he was preparing to force the passage of the river, when a column of grenadiers threw themselves into the stream, carrying their arms on their heads, as the water reached to their shoulders. The enemy, believing themselves about to be attacked by the redoubtable column of Lodi, gave way, and taking the road to the Tyrol, allowed the French to effect the passage without opposition. Beaulieu attempted to make a stand upon the heights between Villafranca and Valleggio; but having learned the movement of Augereau on Peschiera, he immediately retired beyond the Adige, and ascended the right bank by Dolce as far as Caliano. Part of his left ascending the Mincio to join him at Valleggio, came suddenly upon the French head-quarters, and nearly captured the general-in-chief, but was soon dispersed by the troops under Massena; and the remainder of this wing, being detached from Goito, entered Mantua, the garrison of which now exceeded 13,000 men. The investment of that fortress was immediately decided on by Napoleon; materials for the siege having previously been prepared at

¹ The success of this attack was facilitated by the very circumstance which seemed to entail instant failure. Whilst the troops hesitated under the storm of fire with which they were assailed on the bridge, some soldiers slid down by the piles into an island in the river, where they hoped to find some point of attack less exposed to the enemy's fire. Here they discovered that the second branch of the Adda was fordable, upon which a battalion immediately spread itself out *en tirailleurs*, in order to turn the Austrian line; and, thus favoured, the mass of grenadiers passed the bridge at the *pas de charge*.

Napoleon. Alexandria and Tortona, whence they were directed in all haste on Lombardy.

Meanwhile Napoleon took measures for strengthening himself upon the Adige, where his situation had become complicated, and in fact presented a variety of new combinations. The investment of Mantua required that he should be master of the course of the Adige; and the key of this river is Verona, the position of which forms the basis of every system upon that line of operations. He therefore took it upon him to summon the latter city, which was surrendered without resistance, on the 1st of June; and by this precious acquisition he procured three fine bridges on the Adige, and a strong central position, defended by bastions, and protected by two forts perched on the last slopes of the Tyrolese mountains, so as to shut up hermetically the valley of the Adige on the left bank of the river. He also placed garrisons in Crema, Peschiera, and other strong places belonging to the Venetians; and having concluded armistices with the King of Naples and the Pope, occupied Leghorn, where he seized a large amount of English property and merchandise. The investment of Mantua was now converted into a regular siege, the labours of which were intrusted to Serrurier's division, 10,000 strong, whilst the rest of the army remained in observation upon the Adige as far as the western bank of the Lago di Garda. The trenches were opened on the 18th of July; but a new act of the drama was about to commence.

The cabinet of Vienna, justly alarmed at the progress of Napoleon, had resolved to check his career by opposing to him a new army and a new general. Beaulieu was replaced by Wurmser, who, having set out from Mannheim, reached Trent towards the end of July, at the head of an army of 60,000 men. At this time Napoleon had not more than 30,000 men under his immediate command, and 10,000 were engaged under Serrurier in the siege. The Austrians had therefore a superiority of force which seemed to insure them the victory. In the last days of July, Wurmser debouched from the Tyrol; Quasdanovich, with 25,000 men, moving by the left bank of the Lago di Garda upon Salo and Brescia; and the marshal, with the remaining 35,000, descending the Adige in three columns. Napoleon instantly resolved to attack Quasdanovich before he could form a junction with Wurmser on the Mincio. This was his only chance of success, and to secure it he quitted everything. The siege of Mantua was raised; 140 pieces of cannon were abandoned in the trenches; and by the evening of the 30th Napoleon had assembled between Peschiera and Goito the divisions of Massena and Augereau, with the reserve of Serrurier's division.

Next day he passed the Mincio to encounter Quasdanovich. The Austrian general, assailed by a superior force, was driven from Lonato, Brescia, and Salo, and compelled to fall back on Gavardo. On the 3d, Augereau's division, supported by the reserve, advanced upon Castiglione; that of Massena directed its march on Lonato; and Guyeux received orders to debouch on Salo, in order to induce Quasdanovich to continue his retreat by threatening his communications with the Tyrol. Napoleon conceived that he was directing his effort against Wurmser, but, on the contrary, it fell upon the left of Quasdanovich, who was now making another attempt to operate his junction by Lonato. As might be expected, the Austrian was again defeated, and being warmly pursued, was forced to direct his columns on their former position at Gavardo. The same day Augereau attacked and defeated the advanced guard of Wurmser at Castiglione. Napoleon had as yet obtained only partial successes; but they strengthened him in his central position, and gave him the means of dealing heavier blows. The first of these was directed against Quasdanovich, who, on the very next day, was surprised at Gavardo, threatened with an attack in reverse, and

obliged to fall back in great disorder upon Riva; thus definitively ridding Napoleon of a corps formidable from its strength, as well as from the strategic direction which had been assigned to it.

But if fortune seconded Napoleon in this juncture, he was at the same instant exposed to the greatest danger in the midst of his very head-quarters. Massena's division had just quitted Lonato, where Napoleon remained with 1200 men, when all of a sudden an alarm was given that the place had been surrounded by an enemy's corps, and soon afterwards an Austrian officer came to summon him to surrender. Happily his presence of mind did not forsake him. He presumed that this could only be one of the detachments of Quasdanovich which had been separated from the main body in the recent affair of Lonato; and he resolved to extricate himself by audacity from a situation which must have been not a little embarrassing. Assuming a menacing tone, "What means this insolence?" said he. "Do you dare to beard the French general in the midst of his army?" The Austrian officer was confounded, and hearing the word "*fusillade*" significantly pronounced by Napoleon, he became so terrified that he consented to surrender. Two thousand men, provided with four pieces of cannon, then laid down their arms, and discovered, when it was too late, that if they had stood firm, the French general-in-chief and all his staff must have been their prisoners. This corps formed the advanced guard of Quasdanovich, which, in executing a reconnoissance with a view to a junction with Wurmser, had crossed on the march the columns of St Hilaire and Sauret, and had fallen upon the French head-quarters at the very moment when the camp of Gavardo was unexpectedly attacked by the French troops.

The combat which decided the final success of this operation took place on the 5th of August, near Castiglione. Wurmser, still infected with the mania of detachments, had pushed one in the direction of the Lower Po, and left another to blockade Peschiera, so that there remained under his immediate orders not more than 25,000 men. The divisions of Massena and Augereau, with the reserve, presented a force equal to that of the enemy, and the arrival of the division of Serrurier turned the balance decidedly in favour of the French. As soon as the latter came up, Napoleon attacked the enemy's left with his right and centre, defeated it, and forced him to repass the Mincio with the loss of twenty pieces of cannon. Massena instantly crossed the Mincio at Peschiera, and falling upon the enemy's right wing, established before that place, routed and put it to flight. Wurmser now perceived that a prompt retreat could alone save him, and, leaving in Mantua a garrison of 15,000 men, he fell back along the valley of the Adige, warmly pursued by the French as far as the entrance of the Tyrol, which he regained with a total loss of 12,000 men and fifty pieces of cannon.

The Austrians, however, had scarcely re-entered the Tyrol, when, being joined by considerable reinforcements, they once more found themselves stronger than their adversaries; and Wurmser having received positive orders to relieve Mantua, imagined that he could attain this end without fighting, by means of manœuvres alone. Davidowich was to cover the Tyrol with 20,000 men disseminated from the environs of Feldkirch as far as Roveredo; whilst Wurmser himself, with the remaining 26,000, should descend the valley of the Brenta, to debouch on Porto-Legnago and the rear of the French army. But the young chief of the French army was not the man to allow himself to be deceived by false demonstrations. At the moment when Wurmser was meditating this false movement, Napoleon received a reinforcement of 6000 men from the army of the Alps; and being thus strengthened, he resolved to penetrate into the heart of the Tyrol, and to

Napoleon.

Napoleon. fall upon the right of Wurmser at the moment when he was draining the Tyrol in order to manœuvre by his left. On the 4th of September, Wukassowich, who commanded the advanced guard, was expelled from the camp at Mori, and driven back, first on Roveredo, and then on Calliano, where he formed a junction with the mass of the corps. The position of Calliano seemed inexpugnable; but Davidowich, being attacked by a greatly superior force, was compelled to abandon this redoubtable gorge, leaving in the hands of the assailants twenty-five guns and 2000 prisoners. The Austrians retreated in the greatest disorder, and next day the French entered Trent. Meanwhile Davidowich rallied the remains of his corps behind the Lavis; Napoleon, however, resolved to dislodge him; he was attacked by Vaubois, and having in vain attempted to defend the passage of the river, he was thrown back upon Salurn and Neumarch.

In the course of this victorious march, Napoleon learned the movement of Wurmser on the Brenta, and resolved to make the most of it. After a series of successful manœuvres, on the part of the French, Wurmser was attacked on the morning of the 8th of September, and driven back in disorder on Bassano. The French instantly pursued, and reaching the town close on the heels of the fugitives, carried it by main force. Not knowing where to make head, Wurmser, with the left of his *corps de bataille*, retired on Fonteriva, where he passed the Brenta, and took the direction of Vicenza; whilst Quasdanovich, with the right, finding it impossible to gain the Brenta, fell back upon Friuli. In this affair 2000 prisoners, thirty pieces of cannon, and an immense quantity of baggage, fell into the hands of the French. The situation of Wurmser seemed desperate; and he resolved to throw himself into Mantua, and there await the arrival of fresh succours from Austria. A mistake on the part of Sahaguet enabled him to accomplish this more easily than might have been expected.¹ He had flattered himself with appearing before that fortress at the head of 26,000 victorious troops; but in reality he threw himself into the place with no more than 12,000 men, discouraged by defeat, and, instead of raising the siege, about to be themselves invested. The entire garrison having sallied out to forage on the 15th, Napoleon attacked them with his whole force; penetrated as far as St George, which he carried at the point of the bayonet; and having compelled Wurmser to retire within the body of the place, completed the investment of the city and the fortress. The charge of the blockade was intrusted to General Kilmaine, with Serrurier's division, and the rest of the army were placed in observation before the Tyrol.

The position of Napoleon, however, was by no means without difficulty, to say nothing of danger. By the middle of October, Davidowich had received reinforcements which raised the force of his corps to 20,000 men, that of Quasdanovich now amounted to 25,000 combatants, and the Croats were permanently organized into regiments to facilitate the arrival of the levies drawn from the Tyrol, and the recruits raised in the interior. The supreme command was conferred on General Alvinzi, a veteran of high reputation, who, having joined the corps of Davidowich, resumed the offensive, directing that corps by Bassano on Verona, where he hoped to effect a junction with Davidowich, who had received orders to descend the Adige.

Napoleon could not advance to encounter Alvinzi without abandoning Verona, and consequently enabling Davidowich to overthrow Vaubois, unite with Wurmser under Mantua, and thus establish in his rear an army superior in number to all the troops he had been able to collect. Vaubois was too weak to defend the approach to Trent; but in ordering him to assume the offensive, Napoleon hoped to impose on David-

owich. In this, however, he was deceived. On the 3d of November Vaubois was forced to fall back on Calliano; on the 4th Davidowich entered Trent; and on the same day the army of Alvinzi arrived at Citadella and Bassano. At the approach of the enemy Massena fell back on Montebello. Davidowich now marched on Calliano, and Alvinzi prepared to move upon Verona by Vicenza. Napoleon now decided to repeat from right to left the manœuvre which had succeeded against Wurmser from left to right,—that is, after first trying to defeat Alvinzi, and drive him behind the Piave, he proposed to ascend the Brenta, in order to fall upon the rear of Davidowich. With the divisions of Augereau and Massena he advanced towards the Brenta, which the enemy had already passed, and on the 6th attacked their left under Provera at Carmagnano, and their right under Quasdanovich at Lenove, though with only partial success. Provera repassed the Brenta, and Quasdanovich withdrew to Bassano without suffering any serious loss. Meanwhile Vaubois, being warmly pressed on the Adige, was, after two days' fighting, driven from the strong position of Calliano, and obliged to retreat on La Corona. Napoleon flew to this division, harangued the 39th and 85th regiments, which had given way at Calliano, and threatened to inscribe on their colours that they were no longer worthy to belong to the army of Italy. Moved with these reproaches, the soldiers shed tears, and swore to conquer or die when next led against the enemy. Napoleon, however, found it necessary to renounce his projects, and to retire on Verona, where he established the head-quarters of the army. The whole country between the Brenta and the Adige being now in the hands of the enemy, the French general began to be closely pressed, and, not choosing to be more so, resolved once more to fall upon Alvinzi. On the 11th he left Verona with the divisions of Massena and Augereau, and next day attacked the enemy, whom he found in position at Caldiero. But a violent tempest which beat in the faces of the troops, and the strong position of the enemy, rendered all his efforts unavailing; he was repulsed with loss, and forced to return to Verona, where his situation now became more critical than ever. He was everywhere too weak; and the fortune which had hitherto so signally befriended him seemed at length to abandon her favourite. Any other general, in his circumstances, would have thought only of repassing the Mincio, and would thus have lost Italy. But in war it often happens, that to gain all a general must risk all. Reduced to this predicament, Napoleon determined to pass the Adige below the left of Alvinzi, and thus to act on his rear. The project was hazardous in itself; but it was nevertheless wise, because it was the only one which still left him some chance of success.

Having recalled Kilmaine with two thousand men from the blockade of Mantua, Napoleon confided to him the defence of Verona, and on the night of the 14th November he set out from Verona for Ronco, where he threw a bridge over the Adige. On the 15th he passed the river, with the divisions of Massena and Augereau and the reserve of cavalry, forming in all about 20,000 men, and advanced by the three dikes which conduct to Arcole. A brigade of Croats, however, profiting by the advantages of the ground, repulsed the attack of Augereau, whose column had been directed on the bridge of Arcole, and afforded time to Alvinzi to come to their assistance. The latter also sent Provera with six battalions to attack Massena at Porcil, and with the mass of his army retrograded on St Bonifacio. But this unforeseen obstacle did not discourage Napoleon. Perceiving that if he could not attain Villa Nova by the

¹ Napoleon never forgave Sahaguet for this oversight, which deprived him of one of the fairest fruits of his victory of Bassano. His plan had been so ably formed, that, but for Sahaguet's blunder, the destruction of Wurmser would have been inevitable.

Napoleon. left bank of the Alpon, he might act more directly by Porcil on Alvinzi's line of retreat; and sensible that, with this view, as well as to secure his right, and prevent himself from being taken in a *cul-de-sac*, it had become absolutely necessary to make himself master of the village and defile of Arcole, he made fresh efforts to carry the bridge. The greater part of his generals being wounded, he seized a standard, and urged his grenadiers once more to the charge. They advanced boldly amidst a tremendous fire; but the head of the column being shattered the troops gave way, and Napoleon being thrown into the marsh was in imminent danger of being taken. At this critical moment Belliard charged with a company of grenadiers, and rescued the general-in-chief when about to fall into the hands of the enemy. Nevertheless, towards evening, the Austrians abandoned Arcole, on the approach of a brigade which had passed the Adige at the ferry of Albaredo, and was advancing along the left bank of the Alpon. But it was now too late; and Napoleon, not choosing to run the risk of passing the night with his troops crowded in the marshes, in presence of the hostile army deployed between San Bonifacio and San Stephano, and fell back to Ronco, on the right bank of the Adige.

The combat of the second day proved not more decisive than that of the first. It was maintained with equal bravery on both sides; and in the evening Napoleon, from the same motives as before, repassed the Adige. But the third conflict proved decisive. At daybreak on the 17th the French troops resumed their march to the bridge, and drove back the Austrians on Porcil and Arcole. It was not against this point, however, that Napoleon had resolved to direct his principal efforts. Leaving Robert with a demi-brigade to keep the enemy in check, he therefore directed Massena with another demi-brigade on Porcil, whilst the rest of his division remained in reserve near the bridge; and he ordered Augereau to throw a bridge over the Alpon, near the embouchure of the rivulet, so as to be in a condition to act against the Austrian left, and thus take Arcole in reverse. As Napoleon had foreseen, the Austrians, reinforced at Arcole, assumed the offensive, and drove back Robert, whom they pursued with reckless impetuosity. Proud of this success, their deep column continued to advance, and suddenly came upon the main body of Massena's division, placed in ambush amongst some willows, who instantly assailed them in flank, cut off 3000 men, and forced the remainder to retire in disorder on Arcole. The decisive moment had now arrived. Augereau developed his attack, whilst some cavalry appeared on the enemy's flank; Massena debouched by Arcole and St Gregorio; the little garrison of Legnago threatened the enemy's rear; and the latter, unable to maintain themselves in ground favourable for acting on the defensive, were reduced to the alternative of either accepting battle in an open country or commencing a precipitate retreat. Alvinzi durst not risk the former, and on the 18th he retired on Montebello, leaving Napoleon at perfect liberty to turn upon Davidowich.

After a few more successful encounters, which will be found detailed in the article FRANCE, Napoleon had rendered abortive all the efforts of Austria. A fourth army had been baffled; and for two months after the last day of Arcole the French general remained undisputed master of Lombardy. To him this interval was of great importance, as it enabled him to take the necessary measures for consolidating his conquests, and also to procure reinforcements sufficient not only to put him in a condition to maintain himself, but also to insure the fall of Wurmser, and to strike a blow at the very heart of the Austrian monarchy.

All that Napoleon had yet done seemed like the web of Penelope; it was invariably undone by the constancy with which the cabinet of Vienna reinforced its army of Italy, and by the negligence of the Directory, which had so long

delayed to afford him adequate support. In fact, he was treated by the government of France as Hannibal had been by the senate of Carthage. But public opinion forbade the sacrifice of a general and an army that had gained so many victories; and, as the battles of Arcole showed that both were within a hair's-breadth of being expelled from Italy, it was at length resolved to adopt decisive measures. Accordingly, the fine divisions of Bernadotte and Delmas, drawn from the armies of the Rhine, were, notwithstanding the winter, directed across the Alps, and, on joining the French army, would have made its total strength about 75,000 men. On the other hand, by the end of December, Alvinzi having under his orders upwards of 40,000 men, resolved to descend from the mountains, and make another effort for the relief of Mantua. For the fourth time, therefore, the possession of that important place was to be submitted to the arbitrement of arms.

Whilst waiting the arrival of the reinforcements which he expected from the Rhine, Napoleon, apprized that Alvinzi had assumed the offensive, flew to the Adige, to watch the development of his attack. At this moment the division of Serrurier was before Mantua; that of Augereau occupied the line of the Adige from Verona to Legnago and beyond it; Massena was at Verona; and Joubert, with a fourth division, held the important positions of La Corona and Rivoli. Each of these divisions was about ten thousand strong; and Rey, with a reserve of four thousand, occupied Desenzano. The imperialists, as if determined to profit by no lesson, advanced at once on the centre and the two wings of the French army, by Roveredo, Vicenza, and Padua; but Napoleon, as he had not yet ascertained in which of these three directions Alvinzi was carrying the mass of his force, resolved to keep his positions until the Austrian general had developed his projects. On the 12th of January 1797, the column which advanced by Vicenza approached Verona, and drove in the advanced posts of Massena. But the division of that general having debouched on St Michel, the enemy was repulsed with loss; and Napoleon acquired the certainty that he was not in force upon that point. Having received intelligence that the principal corps was advancing by the valley of the Adige, Napoleon instantly set out from Verona with the greater part of Massena's division, leaving two thousand men to keep in check the column of Vicenza; and at the same time he sent orders to Rey to advance from Salo on Rivoli, and to Joubert to maintain himself, at any sacrifice, in advance of Rivoli until his arrival.

Soon after midnight Napoleon arrived. It was a fine clear moonlight, and by the enemy's watch-fires, which illuminated the white peaks of Montebaldo, he could easily distinguish five separate encampments. On the morning of the 14th he made his dispositions for battle, and commenced the attack by directing Joubert against the Austrian centre, whilst a demi-brigade was detached to keep in check Lusignan. The enemy sustained the shock with great firmness, and, becoming the assailant in his turn, forced Joubert to give way; Vial, who commanded the right, also retrograded, and the plateau seemed about to be carried. At this critical moment Napoleon, favoured by the vigorous stand made by one of his regiments in the centre, flew to the left, whither he directed the column of Massena, which had just arrived; the enemy were repulsed, and the French left established itself on the heights of Trombalora. The danger, however, was not yet passed. The right was warmly pursued by the Austrians, who had descended from the heights of San Marco; Quasdanovich, having forced the entrenchments of Osteria, was also beginning to ascend the plateau of Rivoli; and Lusignan was moving by Affi upon the rear of the French. Napoleon was in fact surrounded; but an instant's reflection convinced him, that if he could overpower Quasdanovich, he would have nothing to fear

Napoleon.

Napoleon. from Lusignan, and that matters might easily be re-established on the right. This intuitive judgment decided the fortune of the day. As soon as the head of Quasdanovich's column appeared on the plateau it was assailed on both flanks by the infantry, and in front by the cavalry under Lasalle; and being forced back into the ravine, it was thrown into complete disorder by the explosion of an ammunition waggon in the midst of the troops when crowded together in the hollow. Confusion and terror reigned supreme; infantry, cavalry, artillery, fled pell-mell by Canale. Having thus got rid of Quasdanovich, Napoleon directed his efforts to support Vial, who was now in full retreat. The Austrians, pursuing with headlong impetuosity, had got into disorder, when a charge of two hundred horse completed the confusion; the panic communicated itself to the centre, which immediately disbanded; and it was only behind the Tasso that Alvinzi succeeded in rallying the fugitives. The fate of Lusignan was now sealed. Attacked by Massena in front and by Rey in the rear, his corps was destroyed, and he regained Montebaldo with only a few hundred men.

On the evening of the battle, however, Napoleon learned that Provera, having forced the centre of Augereau's division, scattered along the Adige, had succeeded in passing the river at Anghiari on the 13th, and was directing his march on Mantua. On the 14th the Austrian general was at Nogara, and on the 15th he arrived before Mantua, into which he hoped to make good his entrance by the suburb of St George. But finding it retrenched and occupied by the besiegers, he next day attacked the post of La Favorita, whilst Wurmser sallied out against that of San Antonio. Serrurier, however, succeeded in maintaining his ground; Wurmser retired into the body of the place; and Provera, assailed on all sides by the forces which Napoleon had promptly directed against him, was forced to lay down his arms. Meanwhile Joubert, acting with equal vigour, pursued Alvinzi without intermission, turned both his flanks, and getting upon his line of retreat, made 5000 prisoners. Having lost half his army, the Austrian general now withdrew the remainder behind the Piave, leaving only 8000 men for the defence of the Tyrol, and the French army resumed the positions which it had occupied before the combats of Arcole. Such, then, was the famous battle of Rivoli, in which Napoleon, with only thirty thousand men, made twenty thousand prisoners. But its most important result was the capitulation of Mantua, which surrendered on the 2d of February, thus rendering the French undisputed masters of Lombardy. The terms granted to Wurmser were much more favourable than he had any reason to expect, with a garrison reduced to the last extremity, and suffering from almost every species of privation and misery.

Whilst Napoleon was at blows with Alvinzi, the court of Rome, seduced by the instigations of Austria, had broken the armistice concluded in the month of June immediately preceding, and raised a considerable body of troops, the command of which was intrusted to General Colli, whom the cabinet of Vienna had sent for the purpose. Thinking it necessary to punish this hostile demonstration, partly as an example to others, and partly also to get rid of an enemy seldom dangerous but always inconvenient, Napoleon formed a division, which he placed under the command of Victor, and directed to march upon Imola in the Romagna, where it arrived on the 2d of February, the very day on which Mantua capitulated. The campaign was neither long nor bloody. A corps of 4000 papal troops, which attempted to defend the Senio, was totally routed; Faenza was carried at the point of the bayonet; and Colli, with about 3000 men, were made prisoners. On the 9th Victor arrived at Ancona, where he compelled 1200 men to lay down their arms; on the 10th his van-guard entered Loreto, and rifled the treasury of the Santa Casa; and by

the 18th he had reached Tolentino, where his progress was stopped by the conclusion of peace. The terms were such as Napoleon thought fit to dictate. The pope confirmed the cession of Avignon, the Comtat, and the legations of Ferrara and Bologna; he also ceded the Romagna, obliged himself to pay a contribution of L.1,200,000, and agreed to execute, in the fullest manner, the provisions of Bologna respecting works of art.

The face of affairs being now completely changed, Napoleon hastened to carry the war into the hereditary dominions of Austria. With 55,000 men he resolved to advance against the enemy; and the Directory, with a view to second him, ordered Moreau to repass the Rhine at Kehl, whilst Hoche, after re-organizing the army of the Sambre and Meuse, should again advance upon the Meyn. The cabinet of Vienna had entertained the idea of carrying the theatre of the war into Italy; but it was not till after the capture of Kehl by the Archduke Charles, and the disaster of Alvinzi at Rivoli, that it was resolved to act upon this principle. Accordingly, about the middle of January, the archduke, who had just distinguished himself by a masterly campaign, set out with three divisions of chosen troops to traverse the Tyrol, and to oppose the conqueror of Italy. Meanwhile, as the divisions of Bernadotte and Delmas had actually joined the French army, whilst the Austrian reinforcements were as yet only traversing Bavaria, Napoleon, finding himself ready to take the field before the enemy, resolved to profit by this advantage, anticipate his adversary, and attack him *à outrance*, before his whole force should be assembled. Having arranged his plan of operations, and recalled Victor from Ancona to the Adige in order to cover his communications, he put his army in motion on the 10th of March, and with the mass of his force advanced towards the Tagliamento, whilst Massena was directed to move on Feltre, in order to push the brigade of Lusignan, left in observation on the Piave, and also to menace the right of the archduke. This secondary movement was immediately successful. Lusignan retired, ascending the Piave; but on the 13th, his rear-guard, being overtaken at Longaro, was overpowered, and the general himself made prisoner. Satisfied with having thrown the Austrian brigade on Cadore, Massena now directed his march on Spilimbergo and Gemona, in order more effectually to turn the Austrian right, and occupy the important route of Poteba, of which the enemy might take advantage in order to retire upon Villach. On the 16th Napoleon arrived at Valvasone, on the Tagliamento. The archduke had already commenced his retreat, leaving only a rear-guard on the Tagliamento. But the river being fordable, the French columns rushed into the stream, overthrew the enemy, and pursued them along the road leading to Palmanova. Prince Charles having now divided his army, he himself fell back on Goriza; one of his columns, commanded by Gontreuil and Bayalitsch, with the greater part of the *matériel*, moved by Cividale and the valley of Natissona upon Caporetto; and Ocksay, with the brigade of Lusignan, covered the road from Villach to Chiusa-Veneta. But the Isonzo, from its source as far as Goriza, flows between two chains of mountains which are nearly impassable on the side of Krainburg. Napoleon, therefore, manoeuvred against the left flank of the archduke, with the view of throwing him back into the valley of the Isonzo, where his army would have found themselves in the Caudine Forks; and, for a moment, he entertained some hope of accomplishing his object. The left of the enemy was covered by the town of Gradisca, occupied by four battalions. On the 17th Bernadotte attacked the place in front; whilst Serrurier, passing the Isonzo between the city and Montefalcone, took it in reverse, and forced the garrison to capitulate. Directing Guyeux by Cividale on Caporetto, Napoleon now ascended the left bank of the Isonzo, for the

Napoleon. purpose of cutting off the enemy from the road of Czernita, or obliging him to plunge into the valley of the Isonzo by Canale. But as soon as the French general had developed his movement, the archduke fell back, in all haste, upon Laybach, taking the road by Czernita and Adelsberg, closely followed by Bernadotte. Disappointed in one object, Napoleon instantly turned his attention to another, and directed all his efforts against the column of Gontreuil and Bayalitsch, which, being headed by Massena at Tarvis, was thrown back into the gorges of Oberpreth, and being there surrounded, was forced to lay down its arms. On this occasion, 4000 prisoners, 25 pieces of cannon, and 400 baggage waggons, fell into the hands of the conquerors.

From Laybach the archduke had marched by Klagenfurth on St Veit, where he was joined by the first of the reinforcements sent from Germany; but not believing himself even yet in a condition to deliver battle, he fell back upon Neumarck, and on the 30th Napoleon arrived at St Veit. On the 2d of April Massena forced the gorges of Dirnstein, and at Neumarck and Hundsmarck defeated the enemy's rear-guard, consisting of the grenadiers who had just arrived from the Rhine. The archduke continued his retreat on Vienna, and on the 5th Napoleon arrived at Judenburg. But the contest had now reached its term. Two days afterwards, the Austrians, who had received instructions from Vienna touching a letter which Napoleon had addressed to Prince Charles from Klagenfurth, manifesting a desire of accommodation, demanded an armistice, with a view to treat of the preliminaries of peace. To this proposal Napoleon gladly consented. His position was in fact more brilliant than solid. In these circumstances the negotiations speedily advanced towards a favourable issue; and, on the 18th of April 1797, the preliminaries of peace were signed at Leoben, to which the French head-quarters had been transferred.

The conclusion of peace with Austria was almost immediately followed by the annihilation of the republic of Venice. The government of that state had done everything to call down the vengeance of the conqueror. Besides other offences, a repetition of the Sicilian Vespers had taken place at Verona, where every Frenchman found in the streets or houses was butchered in cold blood, and the commandant, General Balland, forced to retire into the castles with 3000 men. Napoleon now hastened to pour the full storm of his wrath on the devoted republic. The senate, in despair, made the most abject offers of submission; but it was too late. The price paid by the republic for its perfidy and cruelty was the surrender of large territories on the mainland, and five ships of war; the payment of three millions of francs in gold, and as much more in naval stores; and giving up twenty of the best pictures, along with five hundred manuscripts.

After the occupation of Venice, and the dissolution of its oligarchical government, Napoleon established his headquarters at Passeriano, near Udine, where he awaited the arrival of the plenipotentiaries which the emperor was to send to treat of a definitive peace. In order to accelerate the progress of the negotiations, he had, on the 24th of May,

signed a preliminary convention with the Duke de Gallo; but the cabinet of Vienna having refused to ratify this act, he repaired to Milan to hasten the organization of the Cisalpine republic, by annexing to it Modena, Reggio, Brescia, Bergamo, Ferrara, and Bologna—the whole destined to constitute a single state, with about 3,000,000 of inhabitants. He also profited by his stay at Milan to direct the democratic revolution which overturned the oligarchy of Genoa, and placed all the friends of change in entire dependence on France; an event which was soon followed by the establishment of another mushroom state, under the name of the Ligurian republic.

By the treaty of Campo-Formio, concluded on the 3d of October 1797, Austria yielded to France Belgium and the boundaries of the Rhine and the Alps, recognised the Cisalpine republic, and received, as an indemnification for the loss of territory, Venice and her Italian provinces; whilst France assumed the sovereignty of Dalmatia and the Ionian Islands.

Napoleon having thus terminated the most wonderful series of campaigns recorded in the history of war, set out for Paris, where he arrived in the beginning of December. The reception which he met with, on this occasion, was such as would have elated the most modest, and encouraged the least ambitious. It was easy to see that he might aspire to everything in France. Nevertheless, the time had not yet arrived to profit by his fame, and take advantage of his popularity; it was necessary to wait until the Directory had completed its discredit with the country, and lost all hold of public opinion. France had indeed proclaimed him as its hero; but this was not enough, and to become the head of the state, it was necessary to be at the same time its deliverer and restorer.¹

During the negotiations at Campo-Formio, Napoleon had suggested the idea of a descent upon Egypt, though he did not then think of undertaking it himself. The project had been relished by Talleyrand, who had replaced Charles Delacroix in the ministry of foreign affairs. Napoleon now offered to carry it into execution. Europe he considered as but a mole-hill in comparison of Asia, whence "all the great glories" had come. And from the view which he took of the state of India at the time, he conceived, that in undertaking to open a direct communication with that country he was taking the surest means to strike an effective blow at England. The expedition to Egypt had three objects: first, to establish on the Nile a French colony, which, without having recourse to the system of cultivation by slaves, should supply the produce of St Domingo and the sugar islands; secondly, to open new outlets for French manufactures in Africa, Arabia, and Syria, and to obtain, in return, all the productions of these countries; and, thirdly, setting out from Egypt as a base of operations, to carry an army of fifty thousand men to the Indus, and make common cause with the Mahrattas, the Hindus, the Mussulmans, and all the oppressed races of the Indian peninsula. The last was the grand and ultimate object aimed at.

Egypt, it is true, was then a tributary of the Porte, one of the most ancient allies of France; but as the Mamelukes

¹ On his return to Paris, Napoleon took up his residence in the same small and modest house which he had occupied before his departure for Italy, in the Rue Chantierine, where he resumed his favourite studies and pursuits; contented, apparently, with the society of his friends, and carefully avoiding any act which might seem intended or calculated to invite popular notice or distinction. His society was much courted in the highest circles, and he occasionally received company at home; but pride as well as policy led him to shun notoriety, and shrink from being stared at in the streets or saloons as the wonder of the day. On one occasion, when greeted with some noisy demonstration of popular favour, "Bah," said he, "they would crowd as eagerly around me if I were on my way to the guillotine." At this period he was reserved and thoughtful, like one too much occupied with serious designs to take any pleasure in the elegant frivolities of fashionable conversation. Wherever he appeared he was the man of Lodi, of Arcole, and of Rivoli, disdaining to disguise his military bluntness in those brilliant circles where a man of an inferior stamp of character would have been ambitious to shine. Piqued by this haughty demeanour, Madame de Staël made various attempts to enlist him amongst the number of her votaries, but without success. "Whom," said she, one day addressing herself to the victorious soldier, "whom do you consider as the greatest of women?" insinuating a compliment in expectation of an equivalent. "Her," replied Napoleon, drily, "who has borne the greatest number of children." This keen retort was not forgotten, and the daughter of Necker became his declared enemy.

Napoleon. were the real masters of the country, and in open revolt against the Sultan, it was thought that the Divan, already occupied with the war against Paswan Oglou, pasha of Widin, and that against the Wahabees, and obliged, from weakness, to tolerate the independence of a number of refractory pashas, would not, for a mere shadow of sovereignty, throw itself blindly into the ranks of the enemy. The preparations were accordingly carried on with great activity, but with the utmost secrecy. All was under the direction of Napoleon, and his characteristic energy everywhere appeared. To draw the attention of England from the ports of the Mediterranean, he visited those of the Channel, and affected to occupy himself with the project of crossing it, when his thoughts were directed towards the invasion of Egypt. At length, all being ready, he repaired to Toulon on the 10th of May 1798, and, on the 19th, sailed from that port with thirteen ships of the line, six frigates, and a fleet of transports, having on board 25,000 men. He was joined at sea by the squadrons which had sailed from Bastia, Genoa, and Civita Vecchia, with from 7000 to 8000 men on board, destined to form part of the expedition; and on the 9th of June the whole arrived before Malta. The subsequent history of the expedition, until the return of Napoleon, is fully detailed under FRANCE; and in the article EGYPT will be found an account of the final conquest of that country by the British under Abercromby and Hutchinson. It is clear, indeed, that, after the destruction of the French fleet at Aboukir all the chances of success were changed. It is no doubt true that Napoleon might still hope to maintain himself in possession of the country, provided he succeeded in attaching the inhabitants to his cause. But two serious obstacles presented themselves to the attainment of this object; namely, the maritime blockade, which obstructed all exportation; and the peculiar nature of the Mohammedan religion, which forbids all obedience or submission to an infidel power. Nor were these difficulties lessened by the failure of the attack on St Jean D'Acre, which, in proving that the invaders were not invincible, encouraged resistance and invited hostility.¹ The truth of this was soon exemplified by the landing of a Turkish army of 15,000 men in the peninsula of Aboukir, the fort of which they immediately stormed and carried, putting the garrison to the sword. But they paid dear for this momentary success. On the 25th of July 1799, Napoleon pounced on them like an eagle on its prey, and annihilated them by a single blow.

The destruction of the Turkish army having consolidated the position of the French in Egypt, Napoleon decided on returning to France. Even when before St Jean D'Acre, he ascertained that a new coalition had been formed; and at a later period he received, through Sir Sidney Smith, several English journals, and the French gazette of Francfort, which informed him of the reverses sustained by the armies of Italy and the Rhine, as well as of the successive revolutions which had completed the disorganization and debasement of the Directory. The consummation which he had contemplated before leaving France seemed to have at length arrived; and no obstacle stood in the way to prevent his return to that country. Having left the chief command to Kléber, Napoleon sailed from Alexandria on the 24th of August 1799, with a small squadron of four

ships, and, after a passage full of marvellous escapes, landed Napoleon. at Fréjus on the 6th of October. His presence excited the enthusiasm of the people, and was considered by them as the certain pledge of victory. His progress to the capital had all the appearance of a triumphal procession, and, upon reaching Paris, he found that everything was ripe for a great change in France.

The circumstances attending the revolution of the 18th of Brumaire (9th of November) have been narrated in the article FRANCE. That event was not produced, but only accelerated by the return of Napoleon. The necessity of a change in the existing order of things had for some time been generally felt and acknowledged. The Directorial government having lost all hold on public opinion, and become equally feeble and contemptible, it seemed necessary to replace it by an imposing authority; and there is none so much so as that which is founded upon military glory. Napoleon perceived this in all its force. The Directory could only be replaced by him or by anarchy; and, in such a case, the choice of France could not for a moment be doubtful. Accordingly, all parties now ranged themselves under two distinct banners: on the one side were the republicans, who opposed his elevation; and on the other all France, which demanded it. A *coup d'état* was nevertheless necessary to produce the revolution of the 18th of Brumaire; and this was effected by the employment of the troops, although without spilling a drop of blood. Napoleon had for a moment hoped that the projected change would be carried by acclamation. He was disappointed. But, after a short and noisy struggle, the republic, born amidst anarchy, and baptized in blood, expired in clamour and uproar—Siéyes assisting in the demolition of his own work; and the Directory was replaced by a provisional consulate, with Napoleon at its head. The dissolution of the councils was followed by the appointment of a legislative commission, and to a committee of this body was assigned the task of preparing a new constitution, which was afterwards denominated that of the year VIII.

Great as had been the ability displayed by Napoleon in the field, few expected that he would evince equal talents and aptitude for government. At the very first meeting of the consuls, a lengthened discussion took place concerning the internal condition and foreign relations of France, and the measures not only of war, but of finance and diplomacy, which it either was or might be expedient to adopt. To the astonishment of Siéyes, Napoleon entered fully into all these subjects, showed perfect familiarity with them even in their minutest details, and suggested various resolutions, which it was impossible not to approve. "Gentlemen," said Siéyes, on reaching his house, where Talleyrand and others awaited his arrival, "I perceive that you have found a master; one who can do and will do every thing himself." The work of reform proceeded rapidly and surely: order was everywhere established, and vigour infused into all the departments of the state. The situation of France, however, occasioned him some disquietude; and, notwithstanding the chances of success in his favour, he resolved to sue for peace, which he could then do in good faith, because the misfortunes of the preceding campaigns were not his work. But Pitt turned a deaf ear to the application, and by this refusal obliged Napoleon to enter upon that course of

¹ There are two proceedings connected with this expedition for which Napoleon has been severely and justly censured. The one was the wholesale murder of the remains of the garrison of Jaffa, consisting of 2000 men, who had fallen into the hands of the French after the storming of that town. The ruthless conqueror, seeing no ready way of disposing of these unfortunate men, ordered them at once to be shot; and all who had escaped the terrors of the siege perished in consequence. The other point was the poisoning of those of his soldiers who had been seized by the plague during the siege of St Jean d'Acre. He had resolved to march for Egypt, and the 50 poor plague-stricken patients could not be conveniently removed, when their impatient and unscrupulous commander ordered them to be poisoned by opium. His humanity in other instances on this retreat was certainly highly praiseworthy, yet there can be no doubt that in these two cases he obeyed the spirit which, to a great extent, characterized his entire career. This was, to sacrifice anything, no matter how precious—whether truth, honour, or even human life—whenever it materially stood in his way.

Napoleon. victory and conquest which ultimately extended his empire over the greater part of the Continent.

War being thus inevitable, the First Consul issued a decree, dated the 7th of January 1800, ordaining the formation of an army of reserve, to consist partly of veterans, who were ordered to rejoin their respective corps, but principally of a new levy of 30,000 conscripts. He caused arms to be forged; appealed to the sentiment of national honour, and assembled an army, young, it is true, but full of enthusiasm. The miserable state of the army of Italy has already been noticed; but that of the Rhine, when united to the army of Italy, presented a fine and formidable body of men, the command of which Napoleon intrusted to Moreau, at the same time sending him the recruits necessary to complete his different corps, and to put him in a condition to assume the offensive. The remainder of his disposable troops was directed on Dijon, where he organized an army of reserve, amounting to 40,000 men, which, from that central point, might be ready to march into Suabia, Switzerland, or Italy, according as circumstances should require.

Finding that the attention of Melas was exclusively fixed on Genoa, into which Massena, with the remains of his force, had been obliged to throw himself; and being anxious, if possible, to relieve that place, which was closely invested; he resolved to give the preference to the shorter route of the Great St Bernard, leaving that of the St Gothard to be followed by the corps which were on their march from the Rhine. In the beginning of May Napoleon set out for Dijon, and on the 8th he arrived at Geneva, where he made the necessary dispositions for effecting the passage of the Alps. The operations which followed have been pretty fully detailed in the article FRANCE. By a series of well-combined manœuvres and demonstrations, Napoleon deceived Melas as to his movements, descended like a torrent from the Alps upon his line of communications, and, by a single march, conquered Italy. Genoa had indeed surrendered; but the battle of Marengo, fought on the 14th of June, repaired everything, and, by a victory snatched from the enemy, after he thought the fortune of the day decided, completed at one blow the conquest of Italy. Never as yet had Napoleon been in such imminent peril, not even at Arcole; never had genius and fortune more happily conspired to change the fate of battle. The victory was glorious, and its results were immense. A convention was entered into, by which Melas obtained permission to retire with his army behind the Mincio; and, in return, he consented to give up Coni, Alexandria, and Genoa, with the fort of Urbino, the citadels of Tortona, Milan, Turin, Pizzighetone, Piacenza, Ceva, and Savona, and the castle of Arona.

Meanwhile both parties continued their preparations for a renewal of the contest; and as all hopes of peace had entirely vanished, Napoleon resolved to put an end to the armistice in the middle of November, and, notwithstanding the severity of the season, to recommence hostilities. Moreau and Brune accordingly received orders to denounce the armistice, and between the 17th and the 27th all the French troops were put in motion. The fate of the contest was to be decided in Germany, where hostilities recommenced towards the end of November; and, in a few days afterwards, Moreau obtained a decisive victory at Hohenlinden. The battle was obstinate and bloody, but never for an instant doubtful; indeed it is one of the few instances to be met with in war where complete success was obtained by the literal execution of the plan previously devised by the general-in-chief. Moreau lost not a moment in taking measures to improve his success. The Austrians were forced to sue for an armistice, which was concluded at Steyer on the 23d of December; the cabinet of Vienna having consented to detach itself from England, and to treat for a separate peace. A definite treaty of peace was signed at

Lunéville in 1801, by which France secured the boundaries of the Rhine and the Alps. This treaty, in fact, differed but little from that which, in 1797, Napoleon had concluded at Campo-Formio.

But amidst all these successes, the conspiracy of the 3d of Nivose (24th of December) convinced Napoleon that he was still upon a volcano. The plan was simple, for it consisted in obstructing the progress of Napoleon's carriage as it passed along the Rue St Nicaise, and in the same instant exploding a machine crammed with all sorts of combustibles, and hence called *the infernal machine*. Napoleon escaped by a miracle; and the assassins were tried, condemned, and executed, glorying in their design, and lamenting that it had not been successful.

The second coalition being now dissolved, England alone maintained an attitude of hostility to France; but the progress of events soon developed a prospect of an accommodation. Egypt and Malta were at first stumbling-blocks in the way of an arrangement; but the conquest of the one led to an adjustment respecting the other; and at length, after a tedious negotiation, preliminaries of peace were signed at London on the 1st of October 1801, and these were afterwards followed by a definite treaty, which was concluded at Amiens on the 27th of March 1802. But the peace of Amiens, like that of Campo-Formio, proved merely an armistice. It was signed in the midst of mutual suspicion; and, before the ink was dry, difficulties arose, and from day to day accumulated the elements of a speedy and inevitable rupture.

During this short cessation of arms, the attention of the First Consul was occupied with the re-establishment of religion, and the arrangement of a concordat with the pope. The churches were deserted and in ruins; and since the famous civil constitution of 1791, the clergy had been in a state of complete schism. His object was to restore the one and to reconcile the other, but without suffering them to acquire the power and influence they had formerly possessed. His next measure was the establishment of a system of national education; and this was followed by the commencement of the great and difficult but highly important task of providing France with a uniform code of laws. Of the various remarkable codes known generally under the collective designation of *Code Napoléon*, the *code civil de Français* is unquestionably the best. It has continued hitherto to be the law of France, and is perhaps the most valuable result of his extraordinary reign. It was his own proud anticipation that he would go down to posterity with the codes in his hand, and in this he was not mistaken. Innumerable works of public utility were likewise begun. Roads and bridges were planned; museums were founded; and the vain were gratified with rising monuments of magnificence, whilst the reflecting recognised in every such display the depth and forecast of a genius formed for empire. This was more fully evinced in the measures by which Napoleon sought to secure the prolongation of his power. The establishment of the consulate for life, which was decreed on the 2d of August 1802, proved a grand step towards the completion of his design, and formed the primary base of the edifice which it yet remained for him to construct. This dignity had already been prorogated for ten years by a *senatus-consultum* of the 6th of May; but on referring the matter to the people, it was decided that the consulate should be conferred upon him for life. He was now virtually sovereign of France. His task was to terminate the Revolution by giving to it a legal character, that it might be recognised and legitimated by the public law of Europe. He instituted, likewise, a new order of chivalry, called the Legion of Honour, which, if it served to further his scheme of empire, did not militate with that equality which alone he sought to maintain.

Napoleon.

The causes which so soon led to the rupture of the hollow truce of Amiens will be found recorded in the articles FRANCE and BRITAIN. On the 18th of May 1803 Great Britain declared war against France; and that fierce contest recommenced, which, after an unexampled career of victory on the part of Napoleon, was destined to terminate in his downfall. His first measures were, the occupation of Naples and of Hanover; and his next project was one of a far more daring and formidable character, namely, that of invading England, and thus striking a blow at the heart of his inveterate and implacable enemy. (See BRITAIN.)

The English ministry were not without serious apprehensions as to the result of the threatened invasion; and to cause a diversion, they are said to have countenanced the unwarrantable warfare of plots and conspiracies. The projects of Pichegru, Georges Cadoudal, and others of the same stamp, have already been described in the article FRANCE. That assassination was contemplated by some of them, appears from the evidence of Cadoudal; but the real designs of these men have never been brought clearly to the light. Finding himself exposed to the attempts of desperadoes who aimed at his life, Napoleon resolved to deal a decisive blow, which he considered as indispensable to strike terror into his enemies. A distinguished Bourbon was at the gates of Strasburg; the police pretended to have discovered evidence which implicated him in the designs of those who had plotted against the life of the First Consul; and under the first excitement produced by this information, the fatal command was issued to seize the prince and bring him to Paris. The order was promptly obeyed, and the Duc d'Enghien, having been seized at Ettenheim, in the territory of Baden, was carried to Paris, where on his arrival he was tried by a military commission, as an emigrant who had borne arms against France, condemned, and shot almost immediately after the sentence had been pronounced. This was the most unwarrantable occurrence in the life of Napoleon. That he was misled by the infamous reports of the secret police, and by the perfidious suggestions of those around him, may perhaps be true; indeed, there is good reason to believe that such was the case. He was likewise kept in ignorance of the afflicting circumstances which accompanied the catastrophe; and the appeal made to his clemency by the unfortunate prince was infamously withheld until after the sacrifice of the ill-fated victim had been consummated; but, with every allowance which can justly be made, it must nevertheless be admitted that, in commanding the seizure of the duke in a neutral territory, he became answerable for all the consequences which ensued, and that he had the double misfortune to incur the guilt of a public crime, and at the same time to commit a political error of the greatest magnitude.

The conspiracies intended to subvert the power of Napoleon, however, served only to confirm it; and the necessity of restoring to France an hereditary and stable government had now become equally obvious and urgent. A motion was accordingly made and carried in the Tribunate, that the imperial dignity should be conferred upon Napoleon; the legislative body without hesitation adopted the proposition; and a *senatus-consultum* appeared, in which he was declared Emperor of the French, with remainder to his male line, or, in the event of his having no children, to any son or grandson of his brothers whom he might choose to adopt as his heir. This decree was sent down to the departments, and on the 1st of December 1804, the prefects reported that between three and four millions of citizens had subscribed their assent to the proposed measure. By the army the elevation of Napoleon was hailed with enthusiasm; and when he visited the camp at Boulogne, he was received with an excess of military devotion. His coronation took place at Paris on the 2d of December, amidst all that was most splendid and illustrious in that

Napoleon.

capital. The ceremony was performed in the cathedral of Nôtre-Dame, where the Pope officiated on the occasion, and consecrated the diadems, which Napoleon placed on his own head, and on that of the Empress Josephine. In like manner, on the 25th of May 1805, he placed on his head the iron crown of the Lombard kings, in their ancient capital, and henceforth styled himself Emperor of the French and King of Italy; announcing, however, that the two crowns should not be held by the same person after his death.

The history of the wars of the empire belongs to that of France, Spain, Austria, Prussia, and Russia, to which the reader is accordingly referred. The Emperor Napoleon again made an offer of peace, which was rejected, and a third coalition was formed against France. The ostensible objects of this league were, to restore the independence of Holland and Switzerland, to free the north of Germany from the presence of the French troops, to deliver Piedmont, and to compel the evacuation of Italy; but its grand aim and design, in as far as concerned England, was to find employment for the French troops on the Continent, and to avert, for a time at least, the dangers of a threatened invasion. The hopes of the allies were, however, speedily crushed by the decisive victories of Ulm and Austerlitz; and Napoleon would soon have been at liberty to turn his arms against England, had it not been for two events, one of which served in a great measure to counterbalance his successes in Germany. We allude to the battle of Trafalgar, in which, on the 21st of October 1805, the very day after Mack surrendered at Ulm, the French grand fleet was annihilated by one mighty blow, and the means of effecting a descent on England completely destroyed. The other event above referred to was the declaration of war by Prussia, after Austria had been crippled and forced to receive the law from the conqueror, and whilst the Russian army was still behind the Vistula. This rash and headlong conduct was dearly expiated at Jena and Auerstadt, and the dismemberment of the Prussian monarchy formed a just retribution for the double perfidy and presumptuous confidence of the cabinet of Berlin. The campaign of 1807, after a prodigious effusion of blood, terminated with the battle of Friedland; and the peace of Tilsit, which followed, not only confirmed the humiliation of Prussia, but appeared to throw Russia into the arms of France. The French emperor had already made a gigantic stride towards the establishment of an European monarchy, and the effectual exclusion of English commerce from the ports of the Continent, by which means he vainly hoped eventually to reduce Great Britain to the necessity of listening to terms of accommodation.

In prosecution of this system, which ultimately proved the main instrument of his ruin, when, to all human appearance, it seemed about to be crowned with success, Napoleon commenced his aggressions on Portugal and Spain, and thus entangled himself in a struggle which became the proximate cause of his ultimate overthrow. In vain did he bring all his means to bear upon this unhappy contest; in vain did he drive the English under Sir John Moore out of Spain. The formation of a fourth coalition again called him away into Germany, where Austria was actively preparing to take up arms, in the hope of recovering what she had lost, and freeing herself from the yoke of France. The attempt, however, proved unsuccessful; and though accident gave her a temporary advantage at Aspern, the battle of Wagram placed her once more at the feet of the conqueror. At this moment the power of Napoleon seemed irresistible. No enemy opposed him on the Continent except the insurgents in Spain, aided by the English; and had he instantly directed his whole energies to terminate the war in the Peninsula, it is probable that his power would have remained unshaken by any reverse likely to

Napoleon. befall him. But he judged otherwise; and, in seeking to attach Austria to his interests by a marriage with a princess of the imperial family, he became involved in a system of policy, the ultimate term of which was the abdication of 1814. From this moment his ascending movement was stopped; he had reached the culminating point of his greatness; and though his genius had as yet lost nothing of its vigour, his power began to decline.

The events of 1810 and 1811 belong chiefly to the history of Spain, where the genius of Wellington was gradually but steadily maturing a resistance which every day became more formidable. Those of 1812 were fraught with the destiny of Napoleon. He had long regarded a war with Russia as inevitable. The co-existence of two such empires as those of France and Russia seemed to him incompatible; and differences speedily arose which led to a terrible collision. The preparations on both sides were immense; the fate of Europe, or rather of the empire of the world, was about to be decided in a single campaign; but Napoleon contemplated the conflict without dread, because, in his view, it afforded the only means of terminating for ever the long struggle which had consumed his life. The result is well known. Amidst the frozen steppes of the Scythian wilderness perished those invincible legions which had carried the imperial eagles in triumph to Vienna, to Berlin, to Warsaw, and to Moscow. No such catastrophe had ever been witnessed in modern times; all preceding examples of suffering and disaster in war sank into nothing in comparison with it. Yet Napoleon, undismayed by the magnitude of the calamity, displayed the almost miraculous resources of his genius in repairing the losses he had sustained; and his appearance in Germany early in 1813, at the head of a powerful army, is perhaps the most astonishing circumstance in his extraordinary career. But fortune had now completely changed sides. Victorious at Lutzen, at Bautzen, and at Dresden, he was, through the treachery of his allies, and the faults of his lieutenants, defeated at Leipzig, and forced to retreat beyond the Rhine. Still he maintained the struggle with incomparable energy and perseverance; and never did his transcendent genius for war display itself more resplendently than in the astonishing campaign of 1814, when, by incredible efforts, he struggled, though in vain, to expel the invaders from the territory of France. But the battle of Montmatre, followed by the capitulation of Paris, decided the fate of the campaign, and with it that of Napoleon. The marshals were tired of war, the spirit of the nation had sunk under its misfortunes, the people demanded that a term should be put to their sufferings, and Napoleon himself shrunk from entailing upon France the still greater calamities of a civil war. In these circumstances, he resolved to abdicate, and, on the 18th of April, signed an instrument by which he renounced for himself and his heirs the thrones both of France and of Italy.

The allies having left Napoleon the choice of his retreat, he chose the island of Elba, near to his native Corsica, and set out, accompanied by four commissioners, one from each of the great allied powers. He was allowed to retain the title of Emperor, and to take along with him a small number of those veteran soldiers who had accompanied him in so many dangers, and whose attachment was not shaken by his misfortunes. In traversing France on his way to the place of his exile, he had occasion to observe the extreme divergence of opinion respecting himself; for in proportion as he was beloved and regretted in the environs of Paris and the provinces of the east, he was detested in those of the south, where even the respect due to misfortune was denied him; and he was more than once obliged to put himself under the protection of the stranger, to defend his life against the people who had been so often intoxicated with his triumphs. On the 4th of May he

landed in Elba, wherein, being separated from his wife and son, and without any projects for the future, he seemed to regard himself as politically dead to Europe, with no other task remaining for him to perform but that of writing the history of the rise and fall of his power.

Napoleon. Napoleon anxiously watched the progress of events, which outran his expectations; he was also well informed as to what passed at the congress of Vienna; and having learned in time that the ministers of Louis XVIII. had proposed to the congress to remove him from Elba, in order to send him in exile to St Helena, he conceived a project which will appear audacious in history, but which, in reality, circumstances indicated as the only reasonable course to be followed. He resolved to return to France.

His preparations were not long; he brought nothing with him but arms, and trusted that France would provide the rest. After a passage of five days, he landed without opposition at Cannes, near the spot where, fifteen years before, he had disembarked on his return from Egypt. This memorable event took place on the 1st of March 1815. He had no determinate plan, because he wanted particular data as to the state of affairs; his intention was to be guided by events, making provision only for probable contingencies. Nor was he at all embarrassed as to the route he should take; for he required a point of support, and as Grenoble was the nearest fortress, he lost no time in directing his march on that place, which opened its gates to receive him. The enthusiasm of the troops knew no bounds, and the reception which he everywhere met with confirmed him in his project. In fact, his march to Paris was throughout a triumphal procession. In twenty days this new revolution was terminated without having cost a single drop of blood. Amidst the acclamations of all France, Napoleon was reinstated on the throne. The grandeur of his enterprise had effaced the recollection of his misfortunes; it had restored to him the confidence of the French people; and he was once more the man of their choice.

In a proclamation published by the Congress of Vienna to all Europe, it was declared that Napoleon, "by appearing again in France, had deprived himself of the protection of the law, and manifested to the world that there could neither be peace nor truce with him." Nothing remained, therefore, but to commit the future destiny of Europe to the arbitrement of arms. Various attempts were made to open a negotiation with the allies, but all proved abortive; and as Napoleon had no intention to await the onset of his enemies, he resolved to fall upon the Anglo-Prussians, before the troops of Austria or Russia could be in a condition to take part in the conflict. By the end of May he had about 180,000 ready to take the field, and by the middle of July this number would have been increased to 300,000; but by transporting the seat of war into Belgium, he would save France from invasion, and perhaps take the enemy unprepared. These considerations decided him to become the assailant. On the 12th of June he set out from Paris, and on the 14th he established his head-quarters at Beaumont, where, in order to profit by the dissemination of the enemy, he judged it necessary to open the campaign without a moment's delay.

Accordingly, he passed the frontier of Belgium on the 15th, and on the following day advanced to Fleurus, where he discovered the Prussian army ranged in order of battle between St Amand and Sombref. Ney had received orders to push forward with 42,000 men by the Brussels road as far as Quatre Bras, an important point situated at the intersection of the roads leading to Brussels, Neville, Charleroi, and Namur, and there to keep the English in check, and prevent them from advancing to the aid of the Prussians, whom Napoleon proposed to attack with the 72,000 men that remained under his command. The battle of Ligny followed, in which the Prussians were defeated; and so

Napoleon. complete was the rout, that, of 70,000 men, their generals were never afterwards able to assemble more than about 30,000. A night pursuit would have annihilated them. But Ney had been much less fortunate at Quatre Bras, where he displayed great infirmity, neither bringing his whole force to bear on the English, nor throwing himself back on Bry to act on the rear of the Prussians. The Prussian army being thus defeated, Grouchy was detached in pursuit of it with 35,000 men, whilst Napoleon proceeded to turn his efforts against Wellington. It is not necessary here to detail the operations which followed, nor even to describe that fierce conflict which decided the fate of Napoleon, and with it that of Europe. (See FRANCE.) The result, more fatal to France than that of either Agincourt or Poitiers, is known to every one. By the timely arrival of the Prussians, who had given the slip to Grouchy, and their junction with the English, the French army was not only defeated, but totally dispersed.

Napoleon returned to Paris, in the hope that the national spirit might be roused, and that all good Frenchmen would unite in defending their country against another foreign invasion. But he soon found that he had deceived himself. Misfortune had deprived him of all consideration; he experienced opposition where he least expected it; the chambers rose in a state of insurrection against him; and, in a short time, he was compelled to sign a second abdication. He then decided to retire to America, and at first proposed to embark at Bordeaux, where his brother Joseph had hired a merchant-vessel for the purpose. But he afterwards changed his purpose, and set out for Rochefort, where he arrived on the 3d of July. Finding it impossible, however, to put to sea, and nearly equally perilous to return to the interior, he took the resolution of throwing himself upon the generosity of the prince regent of England; and, on the 15th, embarked on board of the *Bellerophon*, in Aix Roads. By a formal decision of the English government, he was sent as a prisoner of war to St Helena, where he pined away in hopeless exile, until death put an end to his misery on the 3d of May 1821. In his will he had expressed a desire that his body should be conveyed to France and buried on the banks of the Seine, "amongst the French people whom he had loved so well;" but this request could not, it seems, be complied with until 1840, when, at the request of the government of Louis Philippe, Britain permitted the removal of his remains to France. The body was accordingly deposited with unparalleled pomp and display in the *Hôtel des Invalides*, on the 15th December 1840. (J. B.—E.)

(For particulars of Napoleon's residence in St Helena, and of his endless petty disputes with his keepers Cockburn and Lowe, see the work of Las Cases; and the *History of the Captivity of Napoleon at St Helena, from the Letters and Journals of the late Sir Hudson Lowe*, by W. Forsyth, 3 vols. 8vo, 1853.)

A few words remain to be said regarding the personal character of the man Napoleon. The materials for such an estimate still continue to increase. The memoirs dictated by himself to Count Montholon and General Gourgaud at St Helena possess great value and interest, notwithstanding the disingenuousness which they display, and the amount of misstatement and palpable untruth in which they abound. Facts and dates and characters are all deliberately sacrificed for the purposes apparently of stage effect and theatrical eclat. More satisfactory materials, however, have been recently accumulating for forming a correct judgment of his policy, motives, and general character. The *Letters and Journals* of Sir Hudson Lowe, already referred to, afford not only information respecting the character of the prisoner of war hopelessly chained to his rocky islet of St Helena, but enable the reader, from the striking conversations which they occasionally record, to obtain a true

glimpse into his past history. Still more satisfactory materials, however, are to be met with in the *Confidential Correspondence of Napoleon Bonaparte with his brother Joseph, sometime King of Spain*, 2 vols., 1855, selected and translated from the *Mémoires* of Du Casse, 1853-55. These letters extend over the period from 1795 to 1815, and refer both to his personal and family history, and to nearly all the remarkable events of his remarkable career. They possess the additional advantage, moreover, of presenting him somewhat in his every-day attire, and may be regarded as the most genuine, because the most unconscious and accidental, disclosure of his character which posterity can now read. They indicate in unmistakeable characters the strange blending of grandeur and meanness, of gigantic power and heartless selfishness, which reigned supreme in his nature. Success was his ruling motive, and to that everything had to succumb. He shed blood like water to make his projects float over all obstacles; and when an object was once set steadily before him, he hewed his way pitilessly on until he reached it. He shot down his prisoners by thousands when they proved an incumbrance, and ordered his own soldiers to be poisoned when they were smitten by the plague. "Sire, General Clarke cannot combine with General Junot, for the dreadful fire of the Austrian battery." "Let him carry the battery," called the chief. "Sire, every regiment that approaches the heavy artillery is sacrificed; Sire, what orders?"—"Forward, forward!" was the reply. "My lads you must not fear death," he said to a regiment of chasseurs before the battle of Jena; "when soldiers brave death they drive him into the enemies' ranks." When the Russian army was making its retreat over a frozen lake after the battle of Austerlitz, the emperor came riding at full speed, shouting to the artillery, "You are losing time: fire upon those masses: they must be engulfed: fire upon the ice!" It is needless to add that the ice was fired upon, and that thousands of Russians and Austrians were buried under the waters of the lake. If the Alps were pronounced impassable; "There shall be no Alps," was made the order of the day. Napoleon can hardly be called cruel or bloodthirsty, but he was as remorseless as fate, and seemed never to have known pity. He would risk everything to gain his end—money, troops, and even himself; but his movements were never reckless, and without due deliberation and insight. "He never blundered into victory," says Emerson, "but won his battles in his head before he won them on the field." "My hand of iron," he said, "was not at the extremity of my arm; it was immediately connected with my head." Embarrassments of conscience and scruples of sentiment and affection were unknown to him. If he had a work to do, nothing could stand in its way. "They charge me," he said, "with the commission of great crimes; men of my stamp do not commit crimes:" such was his justification of himself. While fond of regarding himself, however, as the "Child of Destiny," no man ever more thoroughly understood his business. Nothing was effected by magic; the calmest penetration was brought to bear upon everything; and he knew the value to a grain—of gold, iron, ships, and men, in all their possible combinations. If the enemy had three men for his one, he made the contest a matter of simple calculation; and strained all his superhuman genius for manœuvring and evolution, to attack their forces at an angle, and destroy in piecemeal what he could not crush in the mass. "On any point of resistance he concentrated squadron on squadron in overwhelming numbers, until it was swept out of existence." His troops almost worshipped him: their devotion is best indicated in the order of the day at the battle of Austerlitz, when Napoleon, unlike ordinary generals, promised his troops that he would keep out of reach of fire. With his officers, his freedom and companionship was never so great as with his ordinary troops. "When

soldiers have been baptized," he remarked, "in the fire of a battle-field, they have all one rank in my eyes." He accordingly made merit and personal valour the passports to distinction. The cross of the Legion of Honour was the reward of bravery; and he raised seventeen men from the rank of common soldiers to that of king, marshal, duke, and general. He was nevertheless unjust to his generals when his boundless egotism came in the way; and we find him meanly appropriating the fame due to Kellerman and Bernadotte. Junot, who was true to him through all hazards, he intrigued to ruin, because his manners were too familiar for the taste of the emperor. Here is a glimpse into his relation to men:—"There are two levers for moving men, interest and fear. Love is a silly infatuation, depend upon it. Friendship is but a name. I love nobody. I do not even love my brothers; perhaps Joseph a little from habit, and because he is my elder; and Duroc, I love him too; but why? Because his character pleases me; he is stern and resolute, and I believe the fellow never shed a tear. For my part I know very well that I have no true friends. As long as I continue to be what I am, I may have as many

NARANJOS, a cluster of small islands amongst the Philippines, 12 miles N.E. of Masbate. Long. 123. 54. E., Lat. 12. 29. N.

NARBO MARTIUS. (See NARBONNE.)

NARBONNE, a town of France in the department of Aude, pleasantly situated on a branch of the Aude, in a plain surrounded by small hills, about 8 miles from the sea, and 33 E. of Carcassonne. It is surrounded by walls, and entered by four gates. The streets are narrow, crooked, and dirty, and the houses ill built. There are several public walks in the town, the principal being *L'Allée des Soupirs*, which has a very fine appearance. The cathedral of St Just is the principal building in the town; it is a fine Gothic edifice of the thirteenth century, and is remarkable for the height of its roof, which exceeds 130 feet. The high altar and many of the monuments are of marble; but all the statues have been mutilated by the republicans during the revolution. The choir is the only part of this church which has been finished. The church of St Paul, which was also built in the thirteenth century, is in the Romanesque style. The archbishop's palace is a castellated building with an ancient square tower attached to it. Narbonne contains three hospitals, barracks, a theatre, public library, &c.; and has manufactures of verdigris, leather, linen, and bonnets, besides potteries, brickworks, dyeworks, and distilleries. The honey of the vicinity is highly esteemed; and this, as well as corn, wine, oil, brandy, wax, saltpetre, &c., form the principal articles of commerce. The modern town of Narbonne occupies the site of the ancient *Narbo Martius*, a Roman colony founded in 118 B.C. None of the ancient buildings now remain, though the sites of some may still be traced. The old materials were largely used in the construction of the walls by Louis XII. and Francis I.; but many sculptures, inscriptions, &c., have been collected in a museum, which is one of the richest in collections of the sort in France. After the first colonization of Narbo, many of the soldiers of Cæsar's Tenth Legion were settled here, from whom the town derived the name of *Decumanorum Colonia*. It was taken by the Visigoths in 462, by the Burgundians in 508, by the Franks in 531, and by the Moors in 779. Charles Martel defeated the Moors under its walls, but the town held out until it was taken by Pepin in 759. In the middle ages it was one of the most important commercial towns in this part of France; but afterwards it fell into obscurity, and is now chiefly distinguished for its manufacturing industry. Narbonne was the birth-place of the Latin poet Varro Atacinus, and of the Emperor Aurelius Carus. A court of first instance and one of commerce is held here. Pop. (1856) 12,742.

pretended friends as I please. Leave sensibility to women but men should be firm in heart and in purpose, or they should have nothing to do with war and government." He fought sixty battles, and felt that he must go on fighting or it was all over with him. "My power would fall were I not to support it by new achievements. Conquest has made me what I am, and conquest must maintain me." France both thought and fought with him for a time, but got tired of the game of fighting with her neighbours and impoverishing herself, and in 1814 joined all Europe in crying *assez de Bonaparte*. His absorbing ambition and boundless egotism blighted with death, like the upas-tree, everything that came within his sphere. Millions alike of men and money sacrificed and squandered could, on his principle, produce no permanent result. The world never witnessed a grander attempt to succeed without a conscience. The intellect, the will, the resources of the man seemed often superhuman; but he was destitute of moral principle, and laughed at rectitude. He broke friendship with truth, and thereby exposed himself to that terrible retribution which sooner or later overtakes all insincerity and wrong-doing.

NARBOROUGH, SIR JOHN, a British naval commander, was sprung from an old Norfolk family, and became lieutenant of the "Portland" in 1664. His first engagement was in the contest of June 1666, between Prince Rupert and Monk on the one side, and the Dutch admirals Van Tromp and De Ruyter on the other. His conduct in this hotly-contested action was the cause of his rapid promotion. Before two years had passed he was captain of the "Assurance," and in 1669 he was appointed to command an expedition of discovery to the South Seas. Two years were spent in this voyage. In the following year his courage and ability were again conspicuous at the naval battle of Solebay, and recommended him to the notice of the government. He was soon afterwards promoted to the rank of rear-admiral, and dignified with a knighthood. The great honour of his life, however, was his appointment to the command of the fleet sent in 1675 to suppress the Tripoline piracies. After routing several corsairs, and chasing others into their ports, he arrived before Tripoli at the beginning of 1676. Lieutenant Cloudesley Shovel was despatched to negotiate with the Dey, and at the same time to make observations on the harbour. The attempt at negotiation failed, but the position of the shipping was ascertained. Accordingly, at midnight on the 4th March, the boats of the British fleet entered the harbour, burnt the Tripolitan ships, and returned without the loss of a single man. This bold stroke frightened the Dey into agreeing to a treaty. Scarcely had Sir John Narborough returned home, than he was sent with a squadron on a similar expedition against the Algerines. He committed great havoc among these incorrigible pirates, turned his guns against their capital, and forced them to come to an agreement. No sooner, however, had the admiral sailed out of sight, than the Deys of Tripoli and Algiers both returned to their old piratical practices. Soon after his return to England, Sir John was appointed a commissioner of the navy, a post which he held till his death in 1688. (Allen's *Battles of the British Navy*.)

NARCISSUS, a freedman of the Emperor Claudius, became the secretary of his master, and rose to have great influence in the empire. His unscrupulous cunning, and his power over the mind of the emperor, rendered him a useful tool in the hands of Messalina, the profligate wife of Claudius. To gratify her revenge, he accomplished the destruction of Appius Silanus. For the same end he seized the occasion when Scribonianus was condemned for treason, to implicate many innocent persons in the conspiracy. At length the league between these two wily assassins was dissolved, and they directed their deadly arts against each other. The wary prudence of Narcissus soon

Nardo
||
Narses.

gave him the advantage. Hearing that Messalina, in her headlong career of debauchery, had married C. Silius, he hastened to carry the information to the emperor at Ostia. He returned to Rome with the entire command over the person and mind of the facile Claudius, and ordered Messalina to be immediately put to death. For his prompt conduct on this occasion he was raised to the dignity of the prætorship. It was in opposition to the wishes and influence of Narcissus that Agrippina was elevated to the place of Messalina in A.D. 49. A life-struggle arose in consequence between him and the new empress. He continued to retain the favour of the emperor. But the ruthless and ambitious Agrippina framed and executed a plot which ruined both the emperor and his favourite. In 54 A.D. Narcissus was persuaded to visit the warm baths of Campania for his health, and during his absence his master was poisoned, to make room for Nero. His own death was then accomplished without any difficulty.

NARDO (anc. *Neritum*), a town of Naples, province of Otranto, in a well-cultivated district, 9 miles N.N.E. of Gallipoli. It is well built, and has a cathedral, several other churches, and an hospital. Olives are extensively grown in the neighbourhood, cottons and snuff are manufactured, and a considerable trade is carried on in these articles. In the marshes between Nardo and the sea will-o'-wisp are frequently seen, and have given rise to many local superstitions. Nardo, together with Gallipoli, forms the see of a bishop. Pop. 9000.

NARO, a town of Sicily, province of Girgenti, on a river of the same name, 13 miles E. of the town of Girgenti. It stands on a height which is surrounded by fertile and picturesque valleys; and it contains a royal college and a house of refuge. In the neighbourhood large quantities of sulphur are found, in which, as well as in oil and wine, a considerable trade is carried on. Many ancient remains have been found at Naro. Pop. 10,740.

NARSES, a great general who rose, about the beginning of the sixth century, from the humble position of a slave and eunuch in the household of the Emperor Justinian at Constantinople. Possessing the body of a boy and the voice of a woman, he had yet the soul of a hero, and the large mind and persuasive tongue of a statesman. From a menial office in the palace he rose, in course of time, to be chamberlain and treasurer to the Emperor. His talents were next employed in several embassies. To all these duties he proved himself equal. He was therefore fixed upon by his master as the proper person to counteract the influence which Belisarius was gaining over the army in Italy by his successes against the Goths. Setting out for the scene of war in 538 at the head of 7000 men, he joined Belisarius at Firmium. The purpose of his visit was executed with a vigour and thoroughness that endangered the Roman cause. The army was forthwith divided into two jealous factions. Belisarius found himself hampered and thwarted on all sides both in the council and in the field. In vain he asserted, that he had the imperial authority for exacting absolute obedience. Narses pointed out to him in the commission of the emperor the saving clause, "that the officers should obey him in everything compatible with the welfare of the empire." In vain he drew up his army before the walls of Urbino. Narses decamped with a great part of the soldiers during the night. Meanwhile the Goths, released from every check, had burst forth with fresh vigour, laid Milan in ruins, and inundated the northern provinces of Italy. Justinian then saw that it was time to recall his over-efficient servant.

During the twelve years that followed 539, Narses continued to conduct himself with unfailing tact amid the intrigues and jealousies of the court, and steadily to rise in the estimation of Justinian. In 551 he was chosen to recover those parts of Italy which had been wrested by the

Goths after the departure of Belisarius. The empire was astonished at the choice. But the despised eunuch accepted the high office, and began to manifest all the spirit and ability of one born to command. Prevailing upon Justinian to surrender into his power the imperial treasury, he used the money with no niggardly hand in purchasing equipments, conciliating the soldiers, hiring mercenaries, and bribing enemies. In the spring of 552, a completely-accounted army of 100,000 men was ready to follow him to Italy. He set out from Philippopolis, and reached Salona. He then marched along the shore of the Adriatic, attended by his fleet, until he arrived at Ravenna. Nine days were spent in that city in refreshing his soldiers, and in collecting the fragments of the Italian army. Then hastening by forced marches to meet the enemy, he passed under the walls of Rimini, bent his course over the hills of Urbino, and entered on the Flaminian Way. On an evening of July, the Goths under their valiant King Totila appeared in sight near the town of Taginæ. On the following day the battle began; the Romans were completely victorious, and the Goths left their king and 6000 men dead upon the field. The conquerors then took Rome, and proceeded to receive the submission of the neighbouring fortresses. They were still engaged in reducing Southern Italy in 553, when Teias the successor of Totila, setting out from the foot of the Alps, crossed the Po, eluded those who had been sent to intercept his progress, and confronted Narses on the banks of the Sarnus near Naples. Sixty days were spent in skirmishing between the two armies. At length the Goths were compelled by famine to come to an engagement. The battle raged for two days, until King Teias, his bravest chiefs, and the greater part of his army had fallen, and the remainder of the Goths were obliged to surrender. Narses had now given the death-blow to the Gothic power in Italy, and he supposed that the reduction of several towns throughout the country was the only arduous task that now remained. He was mistaken. Before half a year had passed, a horde of 75,000 Franks and Alemanni, under the command of two brothers, the Dukes Leutharis and Buccellinus, poured down from the Rætian Alps into the plains of Italy. The vanguard of the Roman army under Fulcaris was overwhelmed before them at Parma. Narses himself retired into the fortress of Rimini, and allowed the living deluge to sweep on towards the south. But he immediately set himself to prepare for taking the field, and the winter was spent in exercising his soldiers in all the evolutions of military discipline. In the spring of 554 he mustered an army of 18,000 in the neighbourhood of Rome. By this time a part of the barbarian invaders under Leutharis had returned northward, and had been destroyed by a pestilence on the banks of Lake Benacus. The rest under Buccellinus were advancing from Lucania towards Capua. They took up a strong position on the banks of the Vulturnus, and there they met the approach of Narses. That general, depriving them by a series of skilful manœuvres of the advantage of their ground, attacked them, and almost annihilated their entire army. The Gothic cause in Italy was thus ruined for ever.

Narses was now installed in Ravenna as the exarch of Italy; and for the next fifteen years he ruled with a rod of iron. The licentious soldiery were curbed by a severe discipline; several insurrections were crushed with a merciless rigour; and heavy taxes were wrung from the people to satisfy the avarice of the governor. The Romans, groaning under this tyranny, did not dare to complain during the reign of Justinian. But soon after Justin had ascended the throne in 565, they procured the deposition of Narses. The disgraced eunuch retired to Naples, vowing revenge, and, according to the ordinary account, invited the Lombards to invade Italy. The Romans in their hour of danger remembered their old general, and through the mediation

Narses.

Narusze-
wicz

Nash.

of the Pope, induced him to take up his abode in the capital. But before he could take any measures to save them from the invaders, he died of extreme old age in 568.

NARUSZEWICZ, ADAM STANISLAUS, an eminent Polish historian and poet, was born in Lithuania in 1733. He entered the society of the Jesuits at the age of fifteen; and his talents soon raised him to distinction among his order. After travelling through Germany, France, and Italy, he became a professor in the college of the nobles at Warsaw. His order was suppressed by an edict of the Pope in 1773. But the king Stanislaus Augustus, taking notice of him, presented him to the bishopric of Smolensk, and encouraged him in his literary pursuits. In 1772, Naruszewicz had exhibited an aptitude for historical writing by a happy translation of Tacitus. He was now employed by his royal patron to produce a history of Poland. This production was published in 6 vols. 1780-86, and speedily took its place among standard historical works. An introductory volume on the early and obscure periods of the country's annals was also projected; and materials to the amount of 360 folio volumes were collected. But the historian never began it. The close of Naruszewicz's life was saddened by the disasters of his country. He was promoted to the bishopric of Lukow in 1790. But he was past enjoying the dignity, and died in 1796. Among his other works are a collection of poems, consisting of odes, satires, epistles, and translations from Horace and Anacreon, a description of Taurida, and a Life of the Lithuanian general Chodkiewicz. The works of Naruszewicz form part of the collection of select Polish authors, published by Motowski in 26 vols. 8vo, Warsaw, 1803-5.

NARVA, a town of European Russia, in the government of St Petersburg, is situated on the Narova, about 9 miles from its mouth, and 80 miles S.W. of St Petersburg. It consists of an old and a new town; the latter of which is built of stone, and inhabited principally by Germans. Narva has a castle, two churches, a town-house, an exchange, and an old castle. Nails are manufactured here; and there are several large sawmills. Narva was formerly one of the Hanse towns; and had an extensive trade; but since the foundation of St Petersburg, it has much declined in importance. It is memorable for the battle fought here in 1700, when the Russians were defeated by the Swedes under Charles XII. Pop. (1849) 4051.

NASEBY, a village of England, county of Northampton, and situated at the sources of the Nene and Avon, 3 miles E.S.E. of Welford. It stands on the watershed between the German and Atlantic Oceans, to the former of which flows the Nene, to the latter the Avon. It is chiefly remarkable as the scene of a decisive battle, fought in 1645, when the army of Charles I. was defeated by Cromwell and Fairfax. Pop. 898.

NASH, JOHN, an architect, of Welsh descent, was born in London in 1752. After studying architecture with unwearied perseverance under Sir Robert Taylor, he became a measuring surveyor and speculative builder. In course of time he retired to a small property at Caermarthen. In 1790, however, misfortune induced him to resort to architecture for a livelihood; and in 1792 he took up his abode in London. He soon acquired extensive business; and in 1797 he is found receiving a patent for a new mode of using hollow iron boxes in the construction of the arches and piers of bridges. In 1812 he was employed to plan the laying out of Regent's Park, of which he afterwards designed all the terraces, except Cornwall Terrace. A more successful undertaking was the planning of Regent Street in 1813. In carrying out this plan, he endeavoured to give a picturesque effect by uniting several houses into one façade, and covering the bare brick walls with the newly-introduced Roman cement. In 1815, through royal favour, he was appointed architect, valuer, and agent for

Nash.

letting land, to the Board of Woods and Forests. In this capacity he laid out the routes and designed the architecture of several streets. He also assisted Repton in altering and enlarging the Opera House in 1816-18, built the Haymarket Theatre in 1820-21, commenced Buckingham Palace in 1826, and superintended the improvements in St James's Park in 1827-29. The large fortune which Nash had acquired from these and other enterprises enabled him to retire in 1834. His death took place in May of the following year at East Cowes Castle.

NASH, Richard, better known as "Beau Nash," a famous master of the ceremonies at Bath, was the son of a gentleman of limited means, and was born at Swansea in 1674. From Caermarthen School he was sent to Jesus College, Oxford, to prepare himself for ultimately studying law. But that thoughtless love of amusement which afterwards became his ruling passion soon began to influence him. At the age of seventeen, he entered into a matrimonial engagement, which caused his expulsion from the university. A commission in the army was then bought for him. But even the barrack life of a soldier was too serious an employment; and so, under the guise of studying law at the Middle Temple, he devoted his life to pleasure. A fairly-acquired success at the gaming-table supplied him with money. His fine clothes, his imperturbable effrontery, and especially his scrupulous attention to all the ceremonies of polite life, introduced him in a short time to the leaders of fashion. So eminent a master did he become in the science of gentility, that the members of the Temple appointed him to conduct the pageants with which, in accordance with an old custom, they entertained King William. This difficult duty was performed with a masterly tact, and would have been rewarded with a knighthood had not the uncertain income of the "beau" been inadequate to maintain such a dignity. The notoriety of Nash, however, did not commence until he repaired to Bath in 1704. That city was then a paltry watering-place, where a few visitors sought for health and pleasure in comfortless lodging-houses, ill-regulated entertainments, and assembly-rooms perfumed with tobacco-smoke. With his usual forwardness of spirit, Nash got himself appointed master of the ceremonies, and inaugurated his rule by a thorough reformation. By his exertions a handsome assembly-hall was erected, the streets and houses were improved and ornamented, and Bath began to assume the appearance of a city consecrated to pleasure. Good breeding was installed as the ruling principle of the balls and entertainments, and was guarded by a code of laws rigorously enforced upon all. He constituted himself umpire of all quarrels, and prevented appeal from his decisions by forbidding swords to be worn. He also endeavoured, gambler though he was, to keep the thoughtless young of both sexes from the clutch of designing villains. At the same time, his exertions for the improvement of the city, his native vivacity, and his free though sometimes misdirected benevolence, made him popular with the people of the town. In his old age, however, the act of Parliament against gambling deprived him of the means of subsistence. The absurd pomp with which, in his character of "King of Bath," he was wont to secure the respect of the frivolous and the vulgar, could no longer be maintained. The glory of the old beau faded simultaneously with the gaudy trappings that decked his ungainly person. Yet with tottering steps he continued to pursue those vanities which no longer afforded him any enjoyment. He died in February 1761, and was honoured with a public funeral. A *Life of Richard Nash*, by Goldsmith, was published anonymously, in 8vo, London, 1762, and has been reprinted in the edition of Goldsmith's works by Peter Cunningham, in 4 vols. 8vo, London, 1854.

NASH, Thomas, the most brilliant pamphleteer of the Elizabethan age, was born about 1564, at Lowestoft in Suf-

Nashua.

folk. He became a student of St John's College, Cambridge, and in 1584 took the degree of B.A. With this honour, however, his university career closed. His satirical faculty began to try its edge upon the college authorities; and he was in consequence expelled. The next few years seem to have been spent in visiting the Continent, and moving about without any settled employment. At length, in 1589, he took up his abode in London as a literary adventurer. His pugnacious propensity hurried him at once into the contest with the Puritans. He attacked them with their own favourite weapons of ridicule and invective, and proved more than a match for them. *Pap with a Hatchet*, *An Almond for a Parrot*, and *A Countercuffe to Martin Junior*, following each other in rapid succession, overwhelmed his opponents with a shower of humorous sallies and cutting jibes. Such a clever satirist could scarcely fail to attract notice. Accordingly he soon became a reigning wit at supper-tables, and a choice boon companion among literary men of pleasure. He was also employed in 1590 to assist Kit Marlowe in composing *The Tragedy of Dido*; and in 1592 a comedy of his, entitled *Summer's Last Will and Testament*, was played before Queen Elizabeth. But the wit and the fancy that were so active and lively amid the din of controversy were dull and spiritless in the calm region of the drama. This failure in writing for the stage cut off Nash from almost the only source from which the professional authors of that day derived a tolerable pittance. It is no wonder, then, that we find him in 1592 in the midst of bare poverty, writing *Pierce Penilesse, his Supplication to the Divell*; and, with the graphic strokes of one who was representing a stern reality, describing himself as "sitting up late and rising early, contending with the cold, and conversing with scarcitie," cursing the day of his birth, and scarcely restraining himself from ending his misery with his own hand. His *Christes Tears over Jerusalem*, published in 1593, is written in the same strain. But this melancholy was soon shaken off, when about this time he got once more into the congenial region of satire, and began to attack Dr Gabriel Harvey. That worthy individual, the friend of Spenser and Sir Philip Sidney, was then the common butt of some of the most mischievous wits about town. But "that restless buffoon Tom Nash," as old Anthony Wood calls him, used him worst of all. He twisted the many foibles of the pedantic doctor into the most ludicrous and grotesque shapes, and exposed them to ridicule. He raked up every family scandal, and cast it in his teeth. He even sketched the appearance of the lank and shrivelled old scholar with all the vivid fidelity of a portrait-painter, and held it up before the original to make him mad. In vain the learned doctor most manfully wielded his stately invective and cynical humour. These cumbrous weapons were no guard against the keen and light shafts that came pouring in upon him. The most pungent of Nash's pamphlets in this memorable contest were, *Strange News of the Intercepting certaine Letters and a Convoy of Verses*, 1592, and *Have with You to Saffron Walden*, 1596. At length, in 1597, the battle waxed so hot that the Archbishop of Canterbury interfered, and issued an order that all the books of both the combatants should be seized. In the same year Nash was again employed to write for the stage, and, conscious probably that the faculty of ridicule was the only power of his that could achieve success, he produced a satirical play called *The Isle of Dogs*. The lash, however, had been plied too vigorously. Scarcely had the drama been performed, when the author was lodged in the Fleet prison. He seems to have lain there for several days. This play is his last work on record. His death took place in 1600 or 1601. (See Disraeli's *Calamities of Authors*; and Collier's *History of English Dramatic Poetry*.)

NASHUA, a town of the United States, North America, in New Hampshire, situated at the confluence of the

Nashua and Merrimack rivers, 31 miles S. by E. of Concord, and 40 N.N.W. of Boston. It has seven churches, three newspaper offices, and a bank. The River Nashua affords a great amount of water-power for machinery; it has a fall of 65 feet in 2 miles, and at the driest season discharges a volume of 180 cubic feet per second. Its waters are connected with those of the Merrimack by means of a canal. Nashua is remarkable for its manufacturing industry. The total value of the capital invested in various manufactures is about L.80,000, and the number of hands employed 2300. Cotton is the principal article produced. Machinery, iron, &c., are also manufactured here. The town is connected by railways with the principal towns of New England. Pop. 5820.

NASHVILLE, a town of the United States, North America, capital of the state of Tennessee, is situated on the left bank of the Cumberland River, 230 miles E.N.E. of Memphis, and 206 S.W. of Lexington. It is built on a limestone hill, in the midst of a rich and fertile country; and contains many splendid houses and public buildings. There is a fine square, in which stand the court-house, market-house, and other edifices. The capitol, which was built in 1845, stands on a height called Capitol Hill, 175 feet above the river, and is one of the finest buildings in the States. It is built of limestone, and is 240 feet in length, by 135 in breadth. It contains halls for the state legislature and government offices, and is calculated to have cost L.200,000. The court-house is also a very fine building, with a dome, and a colonnade in the Ionic style. The town has also numerous churches, many of which are very handsome buildings; a university, founded 1806, which had in 1856, 7 professors, about 75 students, and a library of 10,207 volumes; a medical college in connection with the university; several schools; a penitentiary; and a lunatic asylum. Nashville has several manufactories of different kinds, and is the centre of an extensive trade. The River Cumberland is navigable up to this place; and the amount of tonnage belonging to the town in 1852 was 4083, entirely employed in steam navigation. The town is rapidly increasing in wealth and prosperity; and is the centre of several railways, completed or in progress. The assessed value of taxable property in 1857 was L.2,726,327. Pop. (1850) 17,502; (1853) about 20,000.

NASMITH, DAVID, the founder of city missions, was born in Glasgow in 1799, and was early placed in a mercantile house. From the age of fourteen onwards, his life was devoted to the welfare of his fellow-men. He began his philanthropic career by imparting religious instruction to prisoners, and exerting himself to establish schools and Bible associations. The next undertaking that engaged his attention was the establishment of young men's societies. So successfully did he execute this project, that between 1823 and 1826 he had been the means of instituting seventy of these associations in Great Britain, France, and America. He then addressed himself to the great work of his life, the converting of the irreligious of large towns. The Glasgow city mission, established in 1826, was the first result of his zeal. Stimulated by this success, he resolved in 1828 to devote himself entirely to his great enterprise, and accordingly resigned his situation of clerk to the Institution House in his native town, an office which he had held for seven years. On a scanty pittance, supplied by some friends, Nasmith travelled through Ireland, the United States, and Canada, founding missions in all the large towns which he visited. The British capital was the next great field of his labour. Taking up his abode there in 1835, the unwearied philanthropist was engaged for the remainder of his life in establishing the London city missions. Meanwhile the rest of the country was frequently visited, and similar institutions were founded in the large towns of England, and in Edinburgh and the other principal towns

Nasmyth
||
Nassau.

of Scotland. He was abroad on his great errand when he died at Guildford in November 1839. Memoirs of Nasmyth, by Dr John Campbell, were published in 8vo, London, 1844.

NASMYTH, ALEXANDER, a popular Scottish artist, was born in Edinburgh in 1758. His first lessons in art were received in London under Allan Ramsay, and he completed his studies in historical, landscape, and portrait painting during a residence of several years at Rome. Then returning to his native country, he settled down in Edinburgh as a portrait-painter. Among other likenesses, he executed the well-known portrait of Robert Burns. In course of time, however, his strong taste for sketching landscapes led him to concentrate his attention exclusively on this kind of painting. The pictures he began to produce were not characterized by vigorous pencilling or life-like colouring; yet their tasteful simplicity and careful finish rendered them popular among his countrymen. At the same time, he was rising into notice as a teacher of his art. His services in this vocation continued to be more and more appreciated, until he had acquired, in his later years, both ample practice and large emoluments. He died at Edinburgh in 1840. His eldest son and his five daughters inherited their father's artistic skill.

NASMYTH, Patrick, an eminent artist, was the eldest son of the preceding, and was born in Edinburgh in 1786. Like several others of his gifted family, he took to the pencil instinctively at a very early age. His right hand was shortly afterwards damaged by an accident. But its cunning was soon acquired by the left. The almost exclusive attention which he bestowed upon his art speedily rendered him a proficient. Fixing his abode in London at the age of twenty, he plied his pencil in landscape-painting with great vigour and success. The style of his father, which he had adopted, was much improved by the greater warmth of his colouring. His subjects were sometimes Scottish scenery, but he was more successful in representing the placid brooks and rich meadow-landscapes of England. The careful minuteness of detail in some of his pictures was especially admired, and acquired for him the surname of "the English Hobbema." Stimulated by growing popularity, Nasmyth prosecuted his art as enthusiastically as ever. With a reckless ardour he continued to pursue his studies in the open country, under the most inclement weather, until he fell into a decline. As he lay dying in his lodgings in South Lambeth, on the 17th August 1831, a terrific thunder-storm passed over the city. He desired to be raised in bed that he might look on it. Before the thunder had rolled away he had expired.

NASO, a town of Sicily, in the province of Messina, is situated on a hill near the coast, in a richly-wooded country, 43 miles W.S.W. of Messina. It is surrounded by walls, and contains several good buildings. Some trade is carried on at Naso. In the vicinity there are mineral springs. Pop. 8000.

NASSAU, DUCHY OF, a small state of Germany, bounded on the N. by Rhenish Prussia, W. by the same and the River Rhine, S. by Hesse-Darmstadt, and E. by the Frankfort district, Hesse-Darmstadt, and the Prussian district of Wetzlar; between N. Lat. 49. 56. and 50. 48., and E. Long. 7. 30. and 8. 35. There are besides two detached portions, the one in Hesse-Darmstadt, the other in Hesse-Cassel; and including these, the entire territory has an area of 1810 square miles. The surface of the country is hilly, and in many parts highly picturesque. A range of hills, called the Taunus, in the S., between the rivers Lahn and Main, attain the height of from 2600 to 2800 feet; while another range in the northern part of the duchy, called the Westerwald, rises to the height of about 2000 feet. The Rheingau or Rhine district, noted for its fruitfulness and mild climate, is situated

Nassau.

between the Main and the Rhine, to the S. of the Taunus Hills. The chief rivers are, the Rhine, forming the west boundary, and here about 2500 feet wide; and its tributaries the Lahn and Main. The former traverses the centre portion of the duchy, and the latter constitutes its southern frontier for part of its course. Several small lakes occupy the more level parts of the country; while as many as 153 mineral wells are known to exist here. Agriculture and mining are the chief branches of industry carried on. In some parts, especially on the Westerwald, the soil is mostly devoted to pasturage. Rye is the chief crop in the higher districts; while excellent wheat is grown in the lower situations, especially on the banks of the Lahn and Aar. Spelt is produced to a considerable extent, and barley is found almost everywhere, excepting on the Westerwald. The other products are oats and buckwheat, potatoes, rapeseed, flax, succory, tobacco, garden fruits, and grapes. The last form one of the staples of the duchy, which possesses the most famous vine district on the Rhine. It includes, among others, the vineyards of Johannisberg, Rudesheim, Markebrunn, and Geisenheim, and that of Hochheim on the Main. The entire state usually produces wine to the amount of 1,020,000 gallons, of which about three-fourths are from the Rhine district alone.

Of a total area of 1,158,143 acres in Nassau, 493,421 are under forests, 433,684 under tillage, 121,136 meadows, 66,051 pasture, 9598 vines, 4612 gardens, 4041 domains, 769 lakes, and 24,831 waste land, roads, &c. In 1852 the crops were 691,072 qrs. potatoes, 148,982 qrs. rye and buckwheat, and 91,144 qrs. wheat and spelt; and in 1855 there were 195,541 cattle, 136,487 sheep, 44,780 swine, 26,794 goats, 12,020 horses, and 15,097 bee-hives.

Mining is the next most important branch of industry in Nassau. The minerals found include silver, iron, lead, copper, and manganese; but of these, iron is by far the most abundant. It is worked in the valleys of the Lahn and Dill, and the amount produced is, of raw iron, about 12,500 tons annually; of cast iron, about 3500 tons; and of bar iron 3500 tons. The lead mines produce about 170 tons, the copper about 150 tons, and the silver 11,000 oz. annually. With the exception of those connected with metals, the manufactures of Nassau are unimportant. They consist of linen and woollen goods, leather, earthenware, and paper; besides tobacco, oil, spirits, beer, and potash. The trade of the duchy is carried on by means of the rivers Rhine, Main, and Lahn; and by the Frankfort, Castel, and Wiesbaden Railway. The imports include, among other articles, colonial products, salt, cottons, and fancy goods; and the exports, wine, fruit, minerals, cattle, paper, and mineral water. The duchy is a member of the Germanic confederation, to which it sends two representatives, and belongs to the *Zollverein*, or trade union. The government is a limited monarchy, in the hands of the duke, assisted by two chambers of administration. The upper chamber consists of an unlimited number of members belonging to the royal family, nobility, and upper classes; while the lower house is formed of twenty-four members, returned from a like number of electoral districts.

All religions are tolerated in Nassau, but the full rights of citizenship are only accorded to evangelical Protestants and Roman Catholics. The former denomination is under the Bishop of Wiesbaden, and the latter under the Bishop of Limburg. The military force amounts to 5498 men, of whom 4542 form the contingent to the Germanic confederation.

Education is imparted to the people by means of elementary and *real* schools. There were in 1854, 703 of the former, with 992 teachers, and 10 of the latter. In Wiesbaden, the capital, a *realgymnasium* has also been established in connection with the preparatory and middle burgh schools, but no university has as yet been founded in the

Natal. duchy. There are several normal schools and seminaries of Evangelical and Catholic theology, and a military academy. The public library of Wiesbaden contains from 50,000 to 60,000 volumes; and there is a museum in the same town devoted to antiquities. Two literary associations have been established, one for history and antiquities, the other for natural philosophy. There is also a *stadt* theatre in the town. In 1849 thirteen newspapers were published in Nassau.

The budget for 1857 estimates the revenue of the state at L.288,397, and the expenditure at L.376,043. The national debt amounts to L.651,000. Of the revenue, about L.6800 is raised from the duty on mineral water, and L.8900 from that on the baths, which are very numerous here. The mineral wells are chiefly in the possession of the duke, and form a valuable property. In 1856 the total population numbered 432,039 persons, of whom 225,681 were Protestants, 198,960 Catholics, 6927 Jews, 341 German Catholics, and 130 Mennonites. Wiesbaden, the capital, contains 16,000 inhabitants. The duchy derives its name from the castle of Nassau, built by the counts of Laurenburg in the beginning of the twelfth century. In 1255 Walram IV. and Otho, the sons of Henry the Rich, divided the territory between them. The former took the earldoms of Nassau, Idstein, and Weilburg, and became the founder of the present family of Nassau. The descendants of Otho, on the other hand, became the earls of Dillenburg and Siegen, and the founders of the House of Nassau-Orange, to which William III. of England belonged. The counts of the older line soon made considerable additions to their territory by acquiring, among others, the lordships of Mehrenberg and Gleiberg. In 1605, after repeated changes, Lewis II., a member of the Nassau-Weilburg family, became sole master of all the lands in the possession of the Walram line. At his death, however, in 1625, the family was divided into the three branches of

—1st, Saarbruck, divided in the next generation into two branches, called Saarbruck-Sarbruck and Sarbruck-Usingen, both of which were again united in 1735, but became extinct in 1797, and the land devolved on the present line; 2d, Idstein, which became extinct in 1721; and 3d, Weilburg, on which all the states devolved, and since 1816 have formed but one principality. During the French revolution the city of Saarbruck, with its territory upon the left bank of the Rhine, was seized by the republicans. It then comprehended 430 square miles of land, with 53,000 inhabitants; for which, at the pacification in 1803, it received an indemnification of 750 square miles and 93,000 inhabitants, which were added to the earldom of Usingen. The Count of Weilburg had lost on the left bank of the Rhine 170 square miles and 19,000 inhabitants, for which he received on the other side of that stream a territory of 330 square miles, with 37,000 inhabitants. At the period when Napoleon instituted the confederation of the Rhine in 1806, the whole of these families had been united in the person of the existing prince, who then received, in addition to the former territories which he possessed, a tract of land of 650 square miles, with 84,500 inhabitants, and at the same time the title of Duke was conferred upon the reigning prince.

NASSICK, a town of Hindustan, in the British collectorate of Ahmednuggur, within the presidency of Bombay, situated on the Bombay and Agra trunk road, and regarded by Brahmins as the peculiar seat of piety and learning. It contains a great number of ancient Brahminical temples and establishments, very flourishing under the peishwa's sway, and still enjoying great privileges under British rule; although the government has entirely withdrawn from interference with the affairs of the native religious institutions. The population of the town is estimated at 25,000. Distance from Bombay, N.E., 100 miles. N. Lat. 20., E. Long. 73. 47.

Nassick

Natal.

N A T A L.

NATAL, a country on the S.E. coast of Africa, about 300 miles N.E. of British Kaffraria, from which it is separated by a thinly-inhabited country called Kaffraria Proper. It lies nearly between 28. and 31. S. Lat., and 29. and 31. E. Long.; and is bounded on the N. and N.E. by the rivers Tugela and Umzimyati, which separate it from the kingdom of the Zulu Kafirs; on the S.E. by the Indian Ocean; on the S. and S.W. by the River Umzimkulu, which divides it from Kaffraria Proper; while on the W. and N.W. the Kahlamba or Drakenberg Mountains wall it off from the territory of the Orange River republic. Its length is about 200 miles, and its breadth from the sea to the Kahlamba Mountains about 100 miles; area about 17,000 square miles.

The country rises from the sea-coast in a series of terraces to an elevation of several thousand feet, and presents a rare variety of scenery, soil, and climate. A sufficiently clear and practical view of the country, however, may be given by representing it as consisting of three general divisions,—1st. Along the Indian Ocean is a belt of land about 15 miles in breadth, the greater part of the surface of which rises and falls in a succession of round swelling hills and small valleys, carpeted with long grass, over which are scattered clumps of trees, chiefly of mimosa and euphorbia. In some places the uniformity of the scenery is relieved by forests and dense jungle, in others by vast masses of lofty and abrupt hills and deep ravines. This lovely region favours the vegetation both of the tropics and of southern Europe. Sugar, coffee, indigo, and almost every other tropical plant, flourish, along with the mulberry, olive, and vine. Nor is it unfavourable to some of

the productions of a cooler climate; for oats, beans, and potatoes thrive well, especially the first two; maize or Indian corn grows luxuriantly in this as in every part of the country.

2d. Having crossed this belt, we ascend into a country where the hills take a longer sweep, something like the downs of Sussex. They are still covered with long grass, but the wood has disappeared, except in small patches in the hollows and on the banks of the streams. The character of the vegetation has changed; we no longer see that of the tropics. Good crops of wheat, oats, potatoes, and other productions of a temperate climate, are produced; and the district is admirably suited for horses and horned cattle. Many fruits also flourish in this part, among which are the orange, pomegranate, peach, apricot, and granadilla.

3d. Proceeding still farther, and ascending another terrace, we find the hills more massive, with a still longer and bolder sweep, covered with grass, but generally bare of wood. They are frequently flat-topped, and sometimes expand into table-land. At intervals on the crests of the hills we meet with stony ridges, composed of large boulders, stretching across the country like huge dykes. In the distance farther inland we see rugged hills cut by deep ravines, and beyond them the Kahlamba mountain-range rising abruptly like a huge wall 8000 feet above the sea, and nearly 4000 above the country at its base, with here and there buttresses thrown out like towers and battlements,—in summer casting a dark, rugged outline against the deep-blue sky, and in winter radiant in a mantle of snow. Sweeping round to the N.W., the range sinks into lower hills, presenting a softer outline, with passes winding over them.

Natal.

The long coarse grass of the lower country is here exchanged for a shorter and finer kind; and everything about him tells the traveller that he has now reached a land admirably adapted both for horned cattle and for sheep. He finds, too, that the country produces abundant crops of wheat, oats, and other cereals of England; while he is refreshed by the taste of excellent peaches, apricots, nectarines, apples, pears, walnuts, and other fruits of a temperate climate. Scattered at intervals over the whole face of the country are vast clusters of hills, varying in area from 10 to 20 by 15 to 30 miles. These localities seem to have been subject to some violent convulsions of nature; for the hills, or rather mountains, rear their rugged or scarped sides in every fantastic form, overhanging deep and gloomy glens, the channels of rushing rivers or foaming torrents. Some of these romantic regions are almost surrounded by the comparatively tame scenery of long sweeping hills or table-land.

Rivers.

Throughout his journey from the coast upwards, the traveller crosses innumerable streams and several considerable rivers. He scarcely descends into a valley which he does not find traversed by a brook of clear fresh water. Numerous rivers intersect the country, flowing generally S.E. into the Indian Ocean. The largest of them, as the Tugela, the Bushmans, the Mooi, and Umkomanzi, have their sources in the Kahlamba Mountains; while the others, as the Umgeni, the Umlazi, and the Umvoti, spring from the lower ranges of hills. None of the rivers are navigable. Their sparkling waters flow with great rapidity, now between banks fringed with brushwood, now past the scarped sides of mountains which rise abruptly from their stream. Some of them have fine cataracts, as the Umgeni, near Pietermaritzburg, the sheer fall of which is 280 feet. All the rivers partake of the character of mountain streams,—low in the dry season, filling in a few hours in the rainy weather, and rushing down like torrents.

Geology,
soil, &c.

The land on the sea-coast is composed of rounded downs of sand, interrupted by strata of sandstone and shale, traversed by masses of erupted rocks. The latter in some places run out into the sea in the form of dark reefs. Farther in the interior the high lands are composed of stratified sandstone, almost horizontal, and deficient in organic remains. A huge vein of granite seems to run from N.E. to S.W. among these high lands. The Kahlamba Mountains were considered by the late Dr Stanger as divided in regard to geological structure into two parts; one part, forming the W. boundary of the colony—the bold, rugged outline of which we have described—he supposed to consist of granite; for it is so precipitous, and so guarded by rugged hills and ravines at its base, as to be almost inaccessible. The part of the range forming the N.W. limit of the colony exhibits a softer and rounder outline, and is composed of sandstone, with beds of shale traversed by basalt and other volcanic rocks. The soil near the coast seems to be a sandy loam; much of it is formed by the blending of sandstone, shale, and erupted rocks. Farther inland it mostly consists of friable loam, red or brown, resting on clay, ferruginous rocks, or granite. In parts from which wood has been cleared, the soil is a rich vegetable mould. Alluvial soil is not abundant; but at the mouths of some rivers, as well as on parts of their course, level plains occur several hundreds of acres in extent. Iron is found in abundance, and said to be of good quality. Copper has lately been discovered in small quantities. Coal exists in several places, but most of it is rather deficient in bituminous matter, though well adapted for furnaces. In the most remote, and perhaps the coldest part of the country, however, there is coal fit for burning in a common fire-place; but none has yet been found sufficiently near the sea to be useful for steam navigation. There are in the upper part of the country some valuable mineral waters, the chief ingredients of which are carbonic

acid; carbonate, sulphate, and muriate of lime; and sulphate of magnesia. Their temperature is 128° Fahr.

Natal.

Botany.

The flora of the country has been but imperfectly investigated, but it seems to be remarkably rich and varied. It differs from that of the Cape of Good Hope in several respects. Geraniums, heaths, and proteads, so varied and abundant in that country, are here represented by few species, and by no means in large numbers. On the other hand, it has many plants which are either not found, or are but sparingly distributed at the Cape. The tribes chiefly worthy of notice are, the Acanthads; the Amaryllids, having among them the beautiful Natal lily; the Solanads; the Scrophulariads; the Euphorbiads, or spurges; the Papilionaceæ, which are very abundant; and the Asclepiads. Grapes are far more abundant than at the Cape. Ferns are also abundant in some parts. Many indigenous plants grow within the belt of land along the sea, which are hardly ever found elsewhere out of the tropics. Among them may be named three kinds of mangrove, indigo, and the ground-nut.

Climate.

The spring commences in September, and the autumn about March. These transition seasons are, however, short; so that the period from September to March may be considered as summer; that from March to September as winter. The hottest weather is in December and January; the coldest in June and July. In summer rain falls almost daily, accompanied occasionally by thunder-storms. In winter there is but little rain, and the sky is clear and cloudless. In the lower belt of country the average temperature in the summer is 77° to 85°. In winter it ranges from 58° to 70°. In the second division of country, at Pietermaritzburg, the capital, the range of the thermometer in the summer is from 64° to 75°, and in winter from 48° to 60°. The climate, especially for persons taking much outdoor exercise, may be considered as one of the healthiest in the world. Travelling in this country, especially in the early morning, is extremely delightful. The light, elastic, and transparent atmosphere gives an indescribable freshness and vigour to mind and body.

History.

This country was discovered by the Portuguese on Christmas-day 1498, and named Natal in honour of the day. They found it inhabited by a portion of the Kafir race, divided into small tribes, not unfrequently at war with one another, but kind and hospitable to strangers. The Dutch who, after their settlement at the Cape in the seventeenth century, sometimes visited this country, gave a nearly similar account of its condition. Little more is known of it till 1810, when a remarkable man arose in the neighbouring country of the Zulu-Kafirs. This was Chaka, originally the chief of an inconsiderable tribe of Kafirs called Zulus, but who became the chief of another more powerful tribe. The united tribes under his rule became a great nation, and conquered and destroyed other tribes of Kafirs far and wide. Nearly the whole population of Natal was swept away, being either annihilated or incorporated with the conquerors. Of the few who escaped, some fled into the country beyond the Kahlamba Mountains, and others to the Cape frontier, where, under the name of Fingoes, they became the serfs of the Amarosa Kafirs. In 1824, during the reign of Chaka, Lieutenant Fanwell and a small party of British emigrants, chiefly from the Cape, settled in Natal, which they found almost depopulated. Chaka received them kindly, and ceded to them a considerable part of the country. In 1828 Chaka was murdered at the instigation of his brother Dingaan, who assumed the sovereignty. In 1837 a party of the Dutch boers, who, as mentioned in our article CAPE OF GOOD HOPE, had emigrated from that colony, arrived in Natal; they were welcomed by the British settlers, and Retief their leader proceeded to the residence of Dingaan to obtain from him a cession of some part of the country. That chief consented to comply with his wish, upon condition of his recovering for him a large number of cattle stolen from him by a neighbouring tribe. The cattle were recovered; and Retief, accompanied by 65 Boers, proceeded to the residence of the Zulu chief, by whom he was received with apparent cordiality. With the aid of an English missionary, the Rev. Mr Owen, who resided near, a treaty was drawn up by which the whole of Natal was ceded to the Boers. Retief was, however, warned by Mr Owen's servants that the king meditated treachery, but he treated their warnings with indiffer-

Natal.

ence; and so completely did the wily chief, by marks of friendship and hospitality, succeed in disarming the suspicion of his guests, that as they were on the point of leaving him, he induced them to present themselves without their fire-arms, before himself and an array of his most trusted warriors, whom he had ordered to be drawn up to do honour to them on their departure. The warriors chanted the war-song in honour of their guests. In a short time the chief himself intoned a song, in the course of which he uttered the terrible words "Kill the wizards!" In an instant the lines of savage warriors closed in on the Boers, and butchered them to a man in cold blood. Dingaan then despatched a large force to attack the rest of the Boers, scattered in small encampments over the country. Some of them were surprised, and men, women, and children were murdered; others, who had time for defence, repulsed their assailants. A deadly war ensued between the Boers and the Zulus, in the course of which was fought a battle memorable in the annals of border warfare. A handful of Boers, not 400 strong, were encamped in a bend of a small river with precipitous banks, and protected on the outer sides by a barricade formed, in their usual manner, by their waggons lashed together. In this position they were, one Sunday morning in 1838, attacked by Dingaan's forces, upwards of 12,000 strong. A terrible conflict ensued. The Zulu warriors marched up in dense columns, and hour after hour strove in vain to storm the camp. Their close battalions were one after another shattered to pieces by the terrible fire of its brave defenders. At length, towards the afternoon, the attacks of the Zulus became fainter, and their whole army was observed to waver; then the Boers mounted their horses, opened their barricade, and charged their assailants, who broke and fled. The Boers pursued them for many a mile, shooting them down without mercy. The victors lost but two or three men; while the loss of the Zulus is said to have exceeded 2000. After this the war continued with varied success. In the meantime the governor of the Cape, in consequence, as he stated, "of the disturbed state of the natives, arising from the unwarranted occupation of the country by certain emigrants being her Majesty's subjects," sent to Natal a small detachment of troops to prevent further bloodshed, for which purpose it was utterly useless, and was not long afterwards recalled. Towards the close of 1839, a brother of Dingaan, named Panda, whom he had for some cause resolved to put to death, went over to the Boers, carrying with him 4000 men. The combined forces then took the field, but as the Boers did not fully trust their new allies, they kept during the march some miles apart from them. Panda fell in with Dingaan's army and totally routed it, chiefly owing to several of its regiments going over to him during the battle. Dingaan fled from the field with a few followers, and sought refuge with a tribe near Delagoa Bay, by whom he was murdered. The Boers then proclaimed Panda king of the Zulus, and declared their own paramount sovereignty to extend not only over Natal, but over the Zulu country.

They, however, only occupied Natal, where they established a republican form of government. That country at this period seems not to have contained more than 12,000 to 15,000 natives, the broken remnants of tribes who, by hiding in the mountains and forests, had escaped destruction from the Zulu armies. In a short time, however, a considerable number of Panda's subjects flocked in to put themselves under the protection of the Boers. Alarmed by this large accumulation of natives in Natal, the Boers resolved to remove a part of them to a country farther to the south. This project, and also an attack made by the Boers on a tribe in that quarter, represented probably with exaggeration to the governor of the Cape, caused him to resolve to take military possession of Natal. A detachment of troops under Captain Smith accordingly arrived at the port, and encamped in the neighbourhood. The Boers refused to recognise the authority of this officer, annoyed his force in every way, and demanded that he should quit the country. Upon this Captain Smith made a night attack on their camp, situated at the upper end of the harbour of Port Natal. He was repulsed with severe loss, and forced to shut himself up in his camp, which for several weeks he and his little force defended with great gallantry, being compelled to kill their horses for food. In the meantime a Mr King, one of the British settlers mentioned above, started on horseback overland to inform the authorities at the Cape of the position of the troops; and on the 26th June 1842, Colonel Cloete, despatched by the governor of the Cape, arrived at the Port with a detachment of troops on board her Majesty's ship *Southampton*. To this force the Boers made a feeble resistance; the port was taken, and the gallant little band under Captain Smith relieved. Finding further resistance hopeless, the Boers entered into a negotiation with Colonel Cloete. With few exceptions, a general amnesty was granted to them, and protection promised them against the natives. Their private rights to their lands were guaranteed to them, but the special terms by which they were to hold them was reserved for the decision of the

Natal.

government. Shortly after this, Colonel Cloete left Natal, and the command again devolved on Captain Smith. On the military occupation of Natal by government, the natives from the Zulu country poured into it in crowds, and it was then that probably the great bulk of Kafir population settled in it. In 1843 the government signified its decision in regard to the property in land, by causing the governor of the Cape to issue a proclamation declaring that lands were to be held by payment of a small annual quit-rent, and providing for the recognition of claims to particular farms, but confirming such recognition to the cases of persons who had occupied their farms claimed for a year next previous to the arrival of a commissioner to be appointed to register such claims. The commissioner, Mr Cloete, was at the same time sent to Natal. This limitation was scarcely in accordance with the terms of the convention, and was manifestly unfair, as pointed out by Mr Cloete. In the disturbed state of Natal during the preceding year, in a great measure the result of the arrival of her Majesty's troops, which gave courage to the natives to harass the Boers in every direction, it was absolutely necessary for the latter to throw themselves together into camps for their protection, and it was thus impossible for them, in the majority of cases, to occupy their farms. Mr Cloete seems to have done as well as he could under the circumstances. He registered a number of claims as coming strictly under the terms of the proclamation, and a number of others as entitled to favourable consideration. The government, on reference home, would only confirm claims of the first kind; and unfortunately even these claims, or rather rights, were not long afterwards interfered with in several ways. This, added to the previous dislike of the Boers to British rule, caused a large part of them to emigrate from Natal to countries beyond, where, under their leader Pretorius, they again measured their strength with her Majesty's troops. Several attempts have since been made to conciliate them by further and liberal grants of land, but with only partial success; their confidence once destroyed, could not be restored. The errors of the government with regard to these in this respect arose from its attaching too great a value to the grazing land mostly occupied by the Dutch, and its failing to see that Natal, with the large Kafir population within and around it, could not be held by the handful of troops it had there without the presence of the Boers; for, even if British immigrants could have been at once poured in, they could not have supplied the place of men inured to the native warfare. These errors were perceived by Sir Harry Smith, when governor of the Cape in 1848, and the measures devised by him, and carried out by the late lieutenant-governor, by retaining a remnant of the Boers in Natal, contributed largely to the tranquillity of the country, which has enabled it to assume its present satisfactory position. In 1845 Natal was constituted a part of the Cape Colony, and the Roman-Dutch law introduced. But in the same year it was again made a separate government, to be administered by a lieutenant-governor, under the general control of the governor of the Cape.

On the establishment of the colony, the executive functions of Government were committed to a lieutenant-governor, assisted by a council. An executive council composed of four chief officials. The legislature consisted of the lieutenant-governor and a council of only three principal officers; so the government remained until 1856, when the crown granted representative institutions. The legislature now consists of the lieutenant-governor and a council composed of four chief officers, who are *ex officio* members, and of twelve members elected by the people of the several counties and towns of the colony. The qualification for voters is the possession of freehold property worth £50, or the occupation of property at an annual rental of £10; all voters are eligible as members. The executive council is still composed exclusively of permanent officers of the government. By the new constitution Natal is made wholly independent of the Cape.

Each of the counties is presided over by an officer, called the resident magistrate, possessing limited judicial and executive authority. By a law passed in 1854, each county is entitled to a local council, consisting of the resident magistrate, the clerk of the peace, and of persons elected by the inhabitants. The qualifications of electors and members are the same as those for the general council. This system, owing to circumstances, has not hitherto worked well; but we see with regret that proposals are made to abolish it. It probably requires change, but to do away with it seems a step backwards; we are convinced that the prosperity of colonies greatly depends upon such local institutions.

The towns possessing 1000 inhabitants, or upwards, are also entitled to local self-government in the form of corporations. The governing body consists of councillors elected by the people, and a mayor chosen from their number. This system is in operation in the two towns, and works well.

The Roman-Dutch law is the common law of the colony, constituted by ordinances of the local legislature. Trial by jury, both

Natal.

in criminal and civil cases, has been introduced. The courts of law are,—1st, The supreme court, presided over by a single judge, styled the Recorder; 2d, The courts of the resident magistrates of counties, whose criminal jurisdiction extends to cases not punishable with death or transportation. They can only punish by inflicting three months' imprisonment and 25 lashes on an offender, and they can only fine to the extent of L.10. In civil cases their jurisdiction only reaches cases when the amount in dispute does not exceed L.15, with the exception of that of the magistrate of Port D'Urban, which extends to cases involving L.100. From all these courts there lies an appeal to the supreme court. Owing to the uncivilized and peculiar state of the natives in the colony, they are in some respects placed under a different system of government from that applicable to the white inhabitants.

For some time after the establishment of the colonial government the natives were in practice governed by their own laws, administered by Mr Shepstone, under the title of diplomatic agent; a gentleman who, by his tact, ability, and perfect knowledge of their language, had acquired considerable influence over them. This peculiar jurisdiction was legalized in 1848; for Lord Grey, then at the head of the Colonial Office, clearly seeing that it would be impracticable and dangerous to attempt to rule men in a state of barbarism by laws framed for a highly-civilized society, advised Her Majesty to issue letters-patent, retaining and confirming, as to the natives of the colony, their own laws, except so far as they might be repugnant to the general principles of humanity as recognised throughout the civilized world. The lieutenant-governor is armed, as to the natives, with all the powers of a supreme or paramount chief, and with the right to delegate his authority to subordinate officers. In this capacity he is assisted by Mr Shepstone, under whom are magistrates distributed over the colony charged with the administration of native law. These magistrates, for the sake of convenience, are the same persons as the resident magistrates mentioned above; but their jurisdiction is in this respect distinct, and in native cases an appeal lies from them to the governor, and not to the supreme court. It is considered that native law is applicable to cases civil and criminal between natives, and also between the government and natives. In cases of murder and some other crimes, the supreme court has co-ordinate jurisdiction. The crime of cattle-stealing by natives, however, which, if not promptly checked, leads to war and bloodshed, has been placed under the exclusive cognisance of native law, which is far better fitted to deal with it than more civilized codes. Cases of this kind are tried before two magistrates and the chief of the tribe to which the accused belongs.

The system of native government, in spite of some defects and some local difficulties, has worked well, and been one of the chief means of preserving peace in the colony, even when other parts of our South-African possessions were involved in war. The main object of the system is to control the natives by laws suited to their present condition, to modify and alter those laws from time to time as the people advance in civilization, and so gradually and silently to assimilate, or rather to identify them with the laws by which their more enlightened fellow-subjects are ruled.

Population.

The total population is about 125,000 persons, of whom about 8000 are white, the rest natives. The white population is made up of Dutch Boers, settlers from the Cape, immigrants from the United Kingdom and their children, and a few Germans. The Boers—about a third of the white population—are the remnant of the people whose struggles we have described, the bulk of whom have emigrated beyond our boundaries. The colonists from the Cape, mostly of British origin, settled in the country before, or soon after, its occupation by the government; the colonists from the United Kingdom almost all arrived since 1849. The natives are of the Kafir race, for the most part refugees from the Zulu country.

The colony N. of the River Umkomanzi is divided into the following six counties:—D'Urban comprises the country about the Port, and the town of the same name; to the N.E. of this, Victoria stretches along the sea-coast to the Tugela. Above D'Urban, on the higher land, is Pietermaritzburg, containing the capital of the colony of the same name; N. and N.E. of which lie the counties of Umvoti, Weenen, and Klip River, chiefly inhabited by Boers. The country S. of the Umkomanzi, being only inhabited by natives, has not been divided into counties. There are two towns, Pietermaritzburg, the capital, and D'Urban, the port-town; and there are also a number of villages scattered

over the colony. Pietermaritzburg contains about 500 houses, with a white population of about 1600. D'Urban has about 450 houses, and a white population of about 1200. This town stands on the north shore of Port Natal, a large and nearly circular basin communicating with the sea by a narrow channel. In this basin vessels drawing from 20 to 25 feet may be moored at all tides. Its mouth is obstructed by a sandy bar, the average depth of which was formerly not more than from 8 to 10 feet; but in consequence of works which have of late years been carried on, its depth has been increased to from 15 to 20 feet; and there is no doubt that it is capable of being rendered one of the safest and best harbours in this part of Africa.

Natal.
Divisions.

In each of the two towns there is a public school supported by government. The government also assists other schools, under certain regulations, by granting to each a sum equal to that raised by private means. The several missionary bodies have schools in various parts of the colony; and there are some excellent schools established under the auspices of the bishop, both for Europeans and natives. By the new charter L.5000 has been specially reserved out of the revenue for the education of the natives. Public libraries and mechanics' institutions have been founded in Pietermaritzburg and D'Urban.

Education.

The Church of England body, scattered over the colony, is presided over by a bishop, having under him a considerable number of clergymen. A handsome cathedral has been erected at the capital, and a very commodious church at D'Urban. In other places, churches are either built or in the course of erection. The Dutch Reformed Church embraces nearly all the Dutch part of the population. They have a church at Pietermaritzburg, and several in the upper country inhabited by the Boers. The Presbyterian Church, though embracing members of the several sections of the church at home, may be regarded as the representative of the Church of Scotland. It has a very commodious stone church at the capital, and small churches at one or two other places. The Wesleyans have several ministers, two chapels in each of the two towns, one for the natives, the other for Europeans, and other chapels in various parts of the district. The Independents have small congregations at the capital and the Port. The Roman Catholics have a bishop and several clergymen. They have small chapels at each of the two towns. The American mission is composed of ministers of several denominations, chiefly, however, Presbyterian and Independent. Their object being to convert the natives, they agree to drop all minor differences, especially as to church discipline, and to present to the native mind none but the great points of belief to which most Christians assent. They have upwards of ten stations scattered over the country along the sea-coast.

The revenue is chiefly derived—1st, From customs duties; Revenue 2d, From licenses to carry on certain trades, stamps, auction and expenditure. duties, and spirit licenses; 3d, From a tax of 7s. per annum on every native hut; 4th, From fees of courts, fines, postage, &c.; 5th, From quit-rents on land.

The revenue and expenditure in several years were as follows:—

	Revenue.	Expenditure.
1846.....	L.3,073.....	L.6,905
1848.....	9,268.....	10,101
1850.....	23,410.....	21,774
1852.....	25,606.....	25,232
1854.....	31,397.....	31,474
1855.....	34,050.....	33,603

The hut-tax was imposed in 1849, and has yielded an annual revenue of upwards of L.8000 per annum. At the same period the expenditure was largely increased in providing the requisite machinery for the government of the natives, as noticed above.

The subjoined table shows the progress of the commerce of the colony:—

Commerce.

Natal
||
National
Education.

Years.	Imports.	Exports of Colonial Produce.
1846.....	L.41,958.....	L.15,409.....
1848.....	46,204.....	10,683.....
1850.....	111,015.....	15,613.....
1852.....	103,701.....	20,164.....
1854.....	124,722.....	37,039.....
1856.....	102,613.....	53,931.....

In 1853 the value of the chief imports were,—cotton and other dry goods, L.40,000; food, stores, &c., L.30,000; spirits, wine, and beer, L.7800; machinery and iron, L.6600.

The exports in 1853 chiefly consisted of,—grain, flour, &c., L.2832; butter, L.5805; bacon and hams, L.1453; ivory, L.11,065; sheep's wool, L.3556; wood and planks, L.1888. In 1855 the export of wool had risen to upwards of L.8000; that of ivory to more than L.14,000. The exports of some other articles have sprung up or been developed since 1853. In 1856 beef and pork, hides, tallow, and arrow-root became

prominent articles of export. The export of sugar commenced in 1856; and its value was stated at L.483.

Agriculture is steadily advancing. In the upper and cooler parts of the country the cultivation of wheat, oats, and other grains is rapidly increasing; the breeding of cattle and sheep is also making good progress. The manufacture of sugar is progressing very satisfactorily; several mills have been imported and are in operation; and at the beginning of 1856 it was considered that there were nearly 1000 acres of cane under cultivation. There seems, too, no doubt that its production will be highly remunerative. Land is not a tenth of the price it brings in the West Indies and Mauritius, while labour is cheaper. Natal, moreover, has a great advantage over these islands in so far as a European can labour out of doors without danger to health. The cultivation of indigo has been attempted with success. Cotton will grow admirably on the coast lands. (B. C. P.)

Natchez
||
National
Education.
Agriculture.

NATAL, a town of Brazil, capital of the province of Rio-Grande-do-Norte, on the River Grande, about 4 miles from its mouth, and 170 miles N. by W. of Pernambuco. The houses are for the most part built only of earth, and the streets are narrow, crooked, and unpaved. The harbour, which might be made one of the best in Brazil, is at present so filled with mud as to be inaccessible to large vessels. The trade is considerable. Pop. (1851) 12,000.

NATCHEZ, a town of the United States, North America, state of Mississippi, on the left bank of the Mississippi River, 279 miles above New Orleans. It is well and regularly built; and most of the houses are of wood, having gardens and shrubberies attached to them. It has a court-house, jail, hospital, orphan asylum, theatre, and masonic hall. There are several oil-mills; and an extensive trade in cotton is carried on. Pop. (1850) 5239.

NATIONAL EDUCATION.

Meaning of THE word *education* is derived from *e*, out, and *duco*, to lead or draw, and is ordinarily employed to express the whole of the process by which we draw forth the powers and capacities of the human mind into free and full activity.

National education signifies the application of this process to any particular country, so that the mass of the people, in their relative stations, may possess the mental development suitable for performing the duties and carrying on the occupations of civilized life.

In treating of the entire subject of national education there are three inquiries which have to be instituted:—1st, What education, individually and nationally considered, is? 2d, Who is responsible for it? 3d, How is it to be carried on? The first of these questions is *theoretical*, and requires of us to explain *what* any one must be taught before he can be considered, properly speaking, an educated man. The second and third of the above questions are *practical*, and have to point out, the one the proper *agencies*, the other the proper *methods* of national education.

I. EDUCATION THEORETICALLY CONSIDERED.

The meaning of the word education, as above explained, conveys in the main the correct idea of the thing itself. It indicates the fact, that the educating process is not intended so much to pour a given amount of the *material* of knowledge into the mind, as to draw forth and develop its powers and capacities, so that they can act vigorously and intelligently upon any kind of intellectual material that may be offered. Man is placed, according to the constitution of Providence, in the midst of an infinite series of natural agencies, which act upon him through all the five senses. The powers of the mind are so framed, and so adapted to the world in which we are placed, that the phenomena presented to it from without are met by a corresponding series of intellectual activities from within, which receive, mould, adapt, and, if we may so say, *intellectualize* the material thus offered. In this way it is converted into knowledge and experience; the world without having supplied the *matter*, the mind itself having then impressed upon it the given intellectual *form*.

The influences of nature, however, and the powers of mind which grasp and interpret them, stand in a very varied relation to each other. In the infantile state of humanity nature has the preponderance over mind. Surrounding circumstances almost wholly mould the man; because the intellectual power which stands opposed to the phenomena presented, and re-acts upon it, is crude and undeveloped. Hence human life rises very little above the direct attempt at supplying physical wants; and those mental developments which go to form the whole complex idea of civilization hardly come into notice, or even existence.

On the other hand, in a more advanced state of humanity the relative preponderance of mind and nature tends more and more towards the supremacy of the *former*. Nature is gradually combated and subdued; she becomes a servant to human wants instead of a governor; and the arrangements of human life all bear the stamp of a widespread intellectual activity, in place of mere human instinct, seeking to supply the most primitive and most pressing of human necessities.

Now the whole difference between these two conditions of human life is due to *education*, in the most extended sense of the word. It is in proportion as the inward and originally slumbering powers of the human mind are drawn out, that man rises above the sphere of a mere physical existence, and comes to be guided by his reason, his conscience, and his better feelings.

A large portion of human education, thus viewed, must *Spontaneous* education. evidently be purely *spontaneous*. A tribe of people obtaining a fixed settlement in some favourable quarter of the globe, starts, we will suppose, upon its progress towards civilization. The habit of living by plunder or by the chase is first of all exchanged for some settled kind of industry of a pastoral or an agricultural character. Industry gives rise sooner or later to property, and property requires law and government in some form to assure and protect it. With the establishment of fixed principles of government, giving security to life and property, exchange and commerce soon begin to spring up, wealth is produced, and leisure is in this way afforded to some to cultivate further the arts of

National
Education.

life. But when once the rudiments of human knowledge, science, and literature, are brought into existence, in however elementary a form, they soon become nurtured and stimulated, it may be by the desire of gain, or by the sense of the beautiful, or by the impulse to celebrate in verse the praises of the good or the great. Parallel with these various steps of human progress, the religious feelings also become developed, and rise from the gropings of idolatry to the intelligent worship of a supreme being.

All this indicates the process of what we may term the *spontaneous education* of a nation,—an education which, under favourable circumstances, will always be going on-wards, and to which a very large portion of the progress of every nation must ever be due. History, in fact, is the record of the spontaneous education of nations, together with the outward events which accompany it; and the philosophy of history is simply an attempt to comprehend the universal laws of human development, so far as they may be gathered from the phenomena of past ages.

Technical
education.

It is not our object, however, at present to give any disquisition on the spontaneous education of nations, as seen in their history, nor to trace the laws of national growth, as shown in the *philosophy* of history. By education, in the more restricted sense of the term, we mean that process of instruction purposely and consciously adapted to the individual, by which his faculties are drawn forth into full activity, and his mind duly developed and informed. Education, viewed in this light, will of course be greatly modified by the position which each man holds in the process of human development generally. The answer accordingly to the question, Whether any given individual be educated or not? must depend in a great measure upon the age and the country in which he lives. In other words, his *technical* education presupposes and must spring out of the *kind* and *amount* of *spontaneous* education to which he is naturally and necessarily subjected in the course of human life.

Persian
education.

A glance at the history of education in different periods of the world, and amongst different nations, will make this abundantly evident. Perhaps the earliest historical records which we have of the methods and details of education are those which relate to the ancient Persians. Amongst them the entire education of the youth, from their fifth to their twentieth year, was confined to three things,—riding, shooting with the bow, and speaking the truth.¹ The two former of these points do not indicate anything but what might exist in a state of barbarism; but the third presents to us the clear indications of an incipient civilization, just beginning to rise beyond the sphere of mere physical activity, and to regard the mental as well as the corporeal qualities of the pupil. Moral education, in this case, is seen to have preceded intellectual, which in fact does not appear to have existed at all amongst the Persians, with the exception of some slight instruction given to the priestly order in the laws and institutions of their religion.

The description which Xenophon gives of the education of Cyrus is not in contradiction to this account, although it is evident that the *Cyropædia* is rather intended as a type of what the education of such a prince *ought to be*, than any faithful delineation of what it actually was. How far this model education, as described by Xenophon, would fall short of what we now consider necessary even for the very rudiments of mental culture, it is not necessary for us to insist upon. And yet, no doubt, the ideal Cyrus must have been regarded as exhibiting *at that time the highest type of an educated man*.

Greek
education.

No sooner do we pass from the oriental world into the active scene of Greek civilization, than we feel at once that the whole atmosphere of human existence is changed. The

National
Education.

great drama of human history has commenced a new act, and the elements which form the chief interest in it are now of an entirely new character. In the Greek we no longer see humanity under the influence of the senses, nor guided merely by the feelings; the elements of self-consciousness there appear from the very first. The Greek *knows* that he has a soul and an intellect within him; he can place himself in bold contrast with nature; he can look *within* as well as *without*; detect the secret workings of his own mind; analyze the inward phenomena of his being, and strip away the fleeting impressions of the moment from the permanent elements of his more fixed ideas. In a word, he can not only form within himself ideal representations of nature, but he knows that they *are* ideal, and is fully conscious of the part which his own mind has had in constructing them.

In the Greek, accordingly, a higher range of mental faculties comes into play than was seen in the early oriental world. The ideas which these faculties create are vivid and exuberant; the memory is inexhaustible; the imagination fertile almost beyond conception; and the power of expression utters itself in a tongue the most harmonious, the most plastic, and the most versatile which mankind has ever produced. This exuberant power of *representation*, however, not only manifested itself in their life and language,—it not only poured itself forth in poetry and song,—it became, still further, the parent of *art*. The Greek was not content with forming ideals *in his own mind*; he felt impelled to express them *externally*. He must paint them out upon the canvas, hew them into wondrous reality from the solid marble, and erect them aloft in the form of massive temples.

With regard to his mode of life, the Greek was essentially a *social being*—social not from any sense of authority due to a superior, but social from the desire of realizing the utmost degree of elegance and ideal culture in his political existence. He has no great reverence for humanity as such; he will enslave others if he can, so long as he remains free himself; nay, all the world may remain either slaves or barbarians to him so long as his own joyous Greek life can blossom in all the hues of its native beauty.

The main idea of education, therefore, among the Greeks was *to fit men to be brilliant citizens*; to develop their physical energies; instruct them in music, poetry, and rhetoric; give them power to impel, to persuade, or to vanquish, and thus turn them out Greek *politicians* in the highest sense of the word.

"Just as the child," says Cramer,² "when he has made only a few steps, rejoices in his knowledge, looks down upon all other, even *his own* former sports, and begins already to fix the measure of culture; so also did the Greek. Culture, in the broadest sense of the word, bodily as well as mental, formed the distinction between himself and the barbarians,—separated the freeman from the slave, distinguished the instructed man from the manual labourer (*βασαντος*), the rich from the poor, and, finally, the Athenian from the other Greeks." It is in accordance with this whole idea that Plato, in his ideal republic, points out the different classes which must exist in the state—the men of valour, the men of business, and the men of thought; and shows that the state should take up every child, as something belonging to itself, and *cultivate* him for his future functions, whatever they might be, in the body politic.

This self-conscious power which the Greeks possessed was sure eventually to lead them beyond the mere creations of poetry and art. In the person of Socrates it created *Ethics*, as the practical science of life; while in Plato

¹ Herod. i. 136; Strabo, xv.

² *Geschichte der Erziehung im Alterthume*, Erster Band, p. 148.

National
Education.

and Aristotle the whole of the latent elements of Greek culture were developed fully out into the form of pure philosophic Idea.

But here the genuine Greek life was already on the wane. As long as they found free scope for their *imagination*, they presented to the world the most wonderful spectacle of æsthetic life and culture which has ever been realized. Their mission on the great arena of human history had to do primarily with *the beautiful*, and then (so far as the fancy could picture them as ideals) with the *good* and the *true*. But it was not a part of their national character to develop any great and striking manifestation of the practical understanding. Another great nation was already formed, and, as it were, set apart for this mission—a nation which, alike devoid of all high exercise of the imagination on the one hand, and the speculative reason on the other, was already giving a perfect embodiment of a solid practical intelligence, and exhibiting all that strength of purpose, firmness of character, and accumulation of *power* over mankind, which such a mental temperament naturally and necessarily superinduces. It need hardly be said that the *Roman* nationality is here referred to.

Roman
education.

The practical sense of the Romans gave a character to the education of their youth altogether different from what we see amongst the Greeks. In Greece everything was regarded in reference to *the culture of the individual*, and estimated according as it tended to realize some ideal of excellence and beauty. In Rome, on the contrary, *UTILITY* was the main object of all education. The Greek, for example, studied mathematics, but he did so mainly as a means of mental refinement; while the Roman studied mathematics and arithmetic solely for practical purposes in warfare or commerce. Physical education among the Greeks was intended to give elegance to the person; amongst the Romans it was intended to give strength and endurance for labour. In Rome the chief subjects of instruction accordingly were, as with us, *reading, writing, and reckoning*, to which some knowledge of geography and Roman history was added; for these were the pursuits which fitted men for their actual duties in human life.

Another thing, too, which caused the Roman education to approach nearer our own than the Greek did, was the fact of their having to look for their models of literary excellence to a foreign language and literature. The Romans studied Greek much in the same way as we do Latin, as being the best basis for a high mental cultivation. The necessity of doing this gave rise to the *science of grammar*, of which the Greeks, being always confined to one language, had no developed idea. The study of grammar in this way became, under the Roman empire, one of the chief pursuits in the schools of learning, and was considered *indispensable* to a liberal education. Thus, although the æsthetic culture of the Roman was far inferior to that of the Greek, yet in practical vigour of understanding, in the sense of personal right, in all the elements of social morality, and in everything which goes to make up the citizen of a great and a free state, the Roman showed himself far superior.

What would have passed for high cultivation amongst the former people would have been regarded as virtually *useless* amongst the latter; whilst the Greek would have scoffed at the barbarism of the Latin, from his want of elegance, genius, and æsthetic development in general. In answer to the question, therefore, What is to be understood by an educated man? the Greek would have pointed to a man of high physical and mental *refinement*, while the Roman would have pointed rather to the man of *great practical efficiency* in all the affairs of human life.

The idea has been widely entertained, that the rise and spread of Christianity throughout Europe made, as it were, a clean sweep of the old-world civilization, and built up another state of society, based altogether upon new ideas.

National
Education.

This, however, was *in fact* far from being the case. That Christianity introduced a new element into the West, and one of surpassing worth and moral grandeur, every Christian man can testify; but there were many other elements which mingled with it before it formed a new state of society, a new civilization, a new world. The Greek intellect was still busily at work in Christian times, as we find abundantly evinced by the controversies of the early church. The Roman practical understanding was at work also, and aided in the reconstruction of society upon the family as the *social*, and the Roman law as the *political* basis of the whole. The Christian youth, indeed, we know attended the schools of the grammarians and philosophers, even though many of them were yet heathens; and thus, in their very education, the culture of the old world was blended with the advancing Christian ideas of the new.

Middle age
education.

If we come down step by step to the middle ages, we find all along precisely the same phenomena. The Greek ideas continued to exist there, for Aristotle reigned almost supreme in the region of the intellect; and the Roman sense of personal right and civil privilege was there also, for absolutism could gain no sure footing in Europe during the whole of the feudal times. And yet, with all this, society sank down into a condition bordering well nigh upon barbarism. This barbarism, however, was more *apparent* than *real*; for although the culture of the middle ages fell so immeasurably behind that of the classic periods of human history, yet there were *new* elements at work within it, which contained the germs of a still higher moral and intellectual life than had ever before existed. The truth is, the whole of the middle ages present to us an immense transition period; the elements of mental refinement, which had cast a radiance upon the old world, were passing away as the basis of a social state, and the sublime spirituality of the Christian life was struggling to realize itself against a thousand opposing difficulties. It was only when both these elements had become fully blended that the light of modern civilization dawned upon us in its full lustre.

Looking, therefore, at the state of education in the middle ages, it is necessary to make a distinction between the spontaneous and the technical education of that period. The spontaneous education, though not marked by a state of any refinement, yet contained in it elements of unspeakable value. To be a true gentleman in the age of chivalry implied valour, honour, gentleness and respect towards the fair sex, truth, humility, and piety; though it implied no scholastic learning whatever, not even the faculty to read or write. The technical education of the middle ages, on the other hand, was poor enough. It was divided into two branches, called respectively the *Trivium* and the *Quadrivium*. The Trivium included grammar, rhetoric, and dialectics; the Quadrivium comprehended music, arithmetic, geometry, and astronomy. The former was supposed to exhaust the study of *language*, the latter to exhaust the study of *science*; and the man who was master of the whole was considered to have fairly earned the title of possessing *universal knowledge*.

Moreover, poor as was this curriculum, there were very few, in comparison to the whole population, who attempted to master even the Trivium alone; while the man who mastered the Quadrivium also was looked upon as a wonder of the age, as was the case with Albertus Magnus, of whom it is recorded to his undying honour, that he taught the Quadrivium, and knew all that was to be known,—

“Quadrivium docuit, et totum scibile scivit.”

The revival of letters in Europe was due proximately to the influence of classical literature, which was brought into the West by the scholars of Constantinople when that city fell a prey to the conquering power of the Turks. To this were added, in rapid succession, the invention of printing,

National Education.
Influence of the Reformation on education.

the discovery of America, and, lastly, the Reformation. With the Reformation a new era commences in the educational history of Europe. The controversies to which it gave rise brought to light the great principle so long forgotten,—that all human truth must depend ultimately upon the acknowledged validity of the faculties of the human mind, and that the responsibility of every man's faith and practice must rest in the end upon his own individual judgment. Hitherto men had been quietly led by *authority*,—now they were to be guided by their own convictions; and consequently it was a matter of supreme moment that those convictions should be rightly and wisely formed. With the spread of the Reformation, accordingly, the fact dawned upon the mind, that the universal exercise of private judgment must be accompanied by the universal education of those who were to employ it. Without this it was seen the work of reformation would be wholly incomplete; for of what use would be the appeal to individual convictions so long as the people were too benighted to have any? Of what avail the right of private judgment, so long as the masses of mind around them had no judgment at all? With the Reformation, then, *the imperative necessity of educating the whole mass of society, from the highest to the lowest, first grew into a clear conviction*. All the great efforts for accomplishing that end date their origin from this period. In Germany, the cradle of the Reformation, Luther proclaimed the education of the people as the crying want of his times, and wrote a circular letter to the councillors of all the towns in the country, pressing the subject upon their attention. In England, private effort set earnestly about the same business; and if all the funds which were left for educational purposes by our forefathers of this era were properly administered and employed, they would even now go far to place the great majority of our population beyond the reach of ignorance and shameful neglect. In Scotland the parochial system of education in the same way dates its rise from the efforts of John Knox and his coadjutors, who determined that every parish in the kingdom should be supplied with a school sufficient for the whole population, as well as with a church for divine worship.

The Reformation, then, we may set down as a great era,—nay, as *the* great era,—in the history of human education. It was the age in which the necessity of developing the whole of the human faculties became apparent; and of doing this, too, through *all classes* of the community. The only question was, *How* was this great end to be accomplished? In what way was human nature to be more and more perfected? What course should the educator follow in order to bring about the highest results? This has been the real problem of modern civilization, *and it is a problem not yet fully solved*.

Educational Reformers.

For some time great trust, as was natural, was put in *ancient* methods. All teaching was to be done by *words*; the old masters were still to be the guides; grammar, logic, and rhetoric were to be the great instruments of human culture; nay, even the practical sciences were to derive their light from the relics of the old world—from Galen, or Celsus, or Aristotle himself. When the Baconian philosophy, however, became once established, a great change was introduced into the whole idea of scientific teaching. Men, it was seen, were no longer to learn from *books* only, but from things themselves. They were no longer to trust to old-established propositions, but to draw the milk of truth at first hand from the bosom of Nature. Here, accordingly, the old system of logical *verbalism* began to give way to a system of scientific *realism*, in which the perceptions and the observing powers were to mingle their results with the generalizations of the understanding.

Locke.

One of the chief reformers in the department of popular education was John Locke. In a work which he wrote on

National Education.

the principles and methods of education, he condemned the exclusive Latin training of the age, and showed how important it was that a due regard to positive science should be joined to the more direct culture of the understanding, through the medium of *language*; and how necessary it was, also, that practical efficiency should ever be kept in view, if the future man was to become a really useful member of society.

The work, however, which had perhaps the most extensive influence during the last century was Rousseau's *Emile*. Rousseau's fundamental principle was, that human nature is essentially *good*, tending alike towards truth and virtue; and that all the evils, sins, and miseries, which afflict it arise from the anomalies and imperfections of human society. He pictures, accordingly, an ideal case, in which an infant is brought up from the very first according to the principles he has laid down; shows how he is to be shielded from the corruptions of society; how he is to be left open to the influences of nature and conscience; how the mind, free from the trammels of conventionalism, is to be allowed to expand; how the faculties thus become enlightened, the will strengthened, the passions repressed, until he grows up a perfect specimen of what a man *ought to be* in his intellectual, social, and moral relations.

This work of Rousseau, though by no means very deep in its philosophy, nor very profound in its analysis of the human faculties, yet produced a marked effect upon European society. It was written just to meet the spirit of the age. Denouncing, on the one side, the materialistic principles of the French philosophy, which made man merely the creature of habit; but yet, starting from a purely psychological and antitheologic basis on the other, it just supplied the wants of those who were looking out for a safe path between the merest naturalism on the one hand and the old-fashioned methods of verbal authority on the other.

Germany especially felt the effects. A number of men, German who received the name of *Illuminati*, entered into a bond of philanthropy to reform the evils of society, and educate its children on rational and moral principles. And much was such a reformation needed. The old grammar-school methods were miserable enough,—mechanical reading, learning by rote, and a half Latin jargon, which went by the name of *grammar*, were driven into the scholars with all due severity. Everything conspired to make the whole process dull, uninteresting, and repulsive. Against all this, then, the philanthropists protested; and although they ran into some extremes on the other side, yet, by nurturing a kindly spirit towards the young, by studying their wants and aspirations as well as their duties, and by introducing a variety of useful topics hitherto excluded from the very atmosphere of the school-room, they did much to break down old abuses and prepare the way for a better system of things.

The most remarkable results of this whole movement were Pestalozzi. The great merit of Pestalozzi, that for which the world owes him a lasting debt of gratitude, was his clear demonstration of the hollowness and futility of mere verbal teaching, unless it is based upon real mental experiences, *previously acquired*. Nurtured in the material philosophy of the age, Pestalozzi held that all human knowledge is based upon the senses; that the perceptive powers, therefore, must be cultivated in the first instance; and that whatever is afterwards taught by words must be brought back to the testimony of the senses for its verification. This philosophy led him both into a truth and an error. The truth into which it led him was, as I have said, the hollowness of mere verbal instruction. It showed him that words have no *essential* force at all; that the knowledge of a proposition, therefore, does not at all involve the knowledge of the *thing itself* of which it speaks; and that unless the intuitive powers are first

National Education. enriched, all your subsequent teaching will be unavailing, because there is as yet nothing in the mind answering to the terms you make use of.

On the other hand, Pestalozzi's philosophy was undoubtedly imperfect; it laid too much stress upon the senses as the foundation of human knowledge, and too little on the intuitions. His method thus became a constant oscillation between *sense* and *reasoning*. Every principle in arithmetic was to be proved by an appeal to the ball-frame; every proposition in geometry demonstrated by presenting the fact involved in it to the eye; every mechanical power explained by showing its actual effect in nature. He did not seem to comprehend that you may present all these things to the senses as facts, individually, and yet that the intellect may thoroughly fail to grasp the *principles* as matters of pure reason. Thus he left the minds of his scholars with a vast multiplicity of isolated facts, verified *as facts* by the senses, but drew forth very little of that superior power by which the mind comprehends truth in its unity, and groups individual phenomena under the universal conceptions of science.

Since the days of Pestalozzi very little has been done towards developing any well-grounded theory of education. The practical work of popular instruction, indeed, has been going on rapidly in nearly every country in Europe, particularly during the last twenty years; but we are still waiting for some master intellect which shall combine all the scattered elements of *pædagogic* science, and unite them into one broad generalization. In the meantime, the subject almost naturally divides itself into certain main branches, which are treated often in an isolated manner, but which, nevertheless, have drawn forth a large amount of useful observation and remark on the nature and methods of education generally.

Various kinds of education.

The most obvious classification, perhaps, which can at present be adopted is that which divides the entire subject of education into,—1. Physical; 2. Intellectual; 3. Moral; 4. Political; and 5. Religious Training. We mean by this, that education has to contemplate the future man in all these five different points of view, and must aim at drawing forth and confirming those special capacities and aptitudes which will lead to the efficient performance of the work and duty of life in all these several respects.

Physical education.

1. With regard to *physical* education, this has hitherto been left far too much to nature and chance; and we owe it mainly to the improved condition of medical science that public attention has been called to the deficiency. It includes, *first* of all, the *essential conditions of health*, such as cleanliness, fresh air, exercise, diet, alternate periods of labour and recreation; *secondly*, the strengthening and proper development of the bodily powers by means of drilling, marching, and gymnastic exercises; *thirdly*, the formation of certain useful habits, which after a time become almost instinctive. Hand-writing is a habit of this kind, which can be impressed once and for ever on the nervous system; the power of rapid performance on musical instruments is another faculty dependent on the same kind of physical training. Easy and graceful deportment, again, is a trained habit; so also is a clear and correct verbal articulation. In fact, wherever physical action is required, of such a nature that it may be transferred by habit from a *voluntary* act to a *reflex* one, there the use of physical education becomes evident; for every good habit which is thus formed and fixed by early training, whether it be a useful accomplishment, or a graceful deportment, or a facility of correct expression, or any kind of manual dexterity, is just so much *power* actually treasured up in the nervous system, which can be brought forth and applied at any moment, as if it were a kind of living machinery, and that, too, without any trouble or any sense of fatigue to the possessor.

2. With regard to *intellectual* education, the pathway is

longer, and the process more complicated. The following, however, appears to be in the main the order in which the intellectual powers naturally develop, and is consequently the *direction* which the educator ought to follow in applying the means of intellectual training. The first of the faculties which comes into full activity after the senses and physical powers have become duly developed, is that of *perception*. By perception we mean the instinctive interpretation the mind makes of all the phenomena which come to it directly through the senses. It was once remarked by a man celebrated for his great learning and ability, that he had learned more in the first three years of his existence than in all the rest of his life put together. And when we take a child of three or four years old, and see what it has already attained,—how it has learned all its first lessons in time and space,—to how perfect a *use* of the senses it has arrived,—how accurately it can measure the relations of form, of size, and of distance,—how it has advanced in the knowledge of *men* as well as *things*,—how readily it judges of character, reads the human countenance, sides with the good and gentle, and rejoices in all that is genuine and beautiful,—we feel that there is almost a literal truth in the assertion. This faculty of the child, then, by which it learns all these indispensable elements of human knowledge, without effort, without instruction, without the aid of schools or lessons, without anything but *nature* and *life* around it, we call *perception*. The earliest teaching, accordingly, should be in accordance with the method which nature herself points out,—namely, *perceptive teaching*. Everything should be done to fructify and enrich the primary intuitions; for it is only when a store of perceptive knowledge is laid up in the mind that verbal lessons can prove of any avail.

National Education. Intellectual education.

The next great step in the unfolding of our intellectual life is the power of *reproducing* the impressions which have been made by means of perception upon the mind; of *representing* them to ourselves internally, and of occupying our minds not merely with things themselves, but with those inward representations of them. Every impression made on the mind through the nervous system leaves an indelible trace behind it. Of course these impressions are not for a time consciously reproduced; but there arrives a period in the course of our mental development in which we not only reproduce our primary mental impressions, but become conscious of that reproduction, and are fully able to connect the actual perception of a thing with the after representation of it. When the power of mental reproduction arrives at this stage, it is called *memory*. Again, if we employ images within the mind merely *as images*, without any further reference to their external source,—if we combine and expand them, and put them into new forms,—then we term it *imagination*; and lastly, if we attempt to trace the principles of order and arrangement, by which the constant flow of images through the consciousness is regulated, we term these the laws of association. All this group of phenomena, then, we include under one head, and call it *the representative faculty*. The triumph of the representative faculty is seen at length in the creation of *language*; for here not only are our perceptions internally represented and reproduced, but these very inward representations are projected out of ourselves, and embodied in external signs; so that by means of language the mind can place its own work before it, as the object of its own contemplation.

Now, observation shows us, that the period of boyhood is chiefly remarkable for the intense activity of the representative powers. The memory at this time of life is remarkably active; the power of seizing vivid ideas of things, of recalling them again and again, of combining them, associating them, and connecting them with the appropriate words or signs, is in the highest state of intensity. This is seen in the wonderful facility with which languages are acquired through the ear at this early period,—a facility

National
Education.

which gradually dies away as the reasoning faculties become more advanced and mature. Nature herself, therefore, again dictates, that in education our principal aim at this time of life should be to furnish nutriment for the growth and expansion of the powers of inward representation; that is, for strengthening the memory, training and regulating the imagination, giving full play to the laws of association, and producing the capacity of expressing ideas in clear, luminous, correct, and copious language. All these habits of mind can generally be acquired with great facility at this time of life; but if neglected *now*, so difficult does the process of their education afterwards become, that it is a thousand chances to one whether they will ever be acquired to any degree of perfection at all.

The formation of signs for our ideas, and the construction of them into a complete language, paves the way for that higher exercise of mind which we call *thought*, and which is mainly concerned with abstract and generalized conceptions. This faculty, which deals with the general and the abstract, which separates our knowledge into definite parts, arranges it, classifies it, embodies it in accurate terms, expands it into formal propositions, and draws conclusions from one proposition to another, we term *the understanding*. The importance of training the mind to accurate logical thinking can hardly be over-estimated; for although the logical faculty is not the *highest* faculty of our nature, yet it is of all others the most practical, and that which has the closest bearing upon the occupations and duties of life. The illogical mind may be deep, reflective, and suggestive of many new ideas, but its knowledge is held loosely together, the connection between one idea and another is hardly perceived, and there is no system or order in the way in which truth is apprehended and retained. The main portion of our intellectual education, as the mental powers become somewhat mature, should accordingly be directed to the regulation and the development of the understanding; and this, according to universal experience, is best done by means of linguistic studies on the one hand, and mathematical and scientific studies on the other.

The goal and summit of our intellectual life is at length attained in the full and free development of the *reason*. By reason we mean that power which is concerned in the formation of our last and deepest convictions,—it is that image of the Divine thought which descends to the very basis of human truth, calls all earthly authority before its bar, and judges the right and the true, subject to no power, and amenable to no laws, but those of the infinite and eternal reason itself, of which it is an emanation. By means of the reason, knowledge is not only arranged, but traced upwards to its highest and most general conclusions; the laws by which the worlds, both of nature and mind, are governed, are laid bare, and in the midst of the immense and bewildering multiplicity of phenomena around us, a hidden unity is grasped that connects the whole as the work of one great Author, and as conspiring to one beneficent end. To nurture up this power of insight into full vigour is the highest problem of education, intellectually considered, and the result, when attained, is what we term scientific and philosophic genius.

Moral
education.

3. We come next to *moral education*, which all resolves itself into *training the will to act firmly in accordance with the dictates of conscience*. Just as the intellect, commencing with mere sensation and perception, rises through a series of stages up to the highest exercise of reason, so also the will, commencing with a mere instinctive tendency to action, rises up step by step to perfect freedom and self-control; and just as intellectual training aims at perfecting the powers of reason, so does moral training aim at perfecting the self-control of the will. The child in the perceptive age requires especial care in relation to the regulation of the will. The rise and development of self-conscious-

National
Education.

ness in the child is always accompanied with a sense of *inward power* in relation to the world without. The meaning of *play* at this early period is the instinctive exercise of this new-found power in our nature; and its real value lies in the nurturing of our self-consciousness, and the realization of our nascent ability to conquer the material world around us, and bend it to our service. The very same tendency leads to the desire of tyrannizing over others. The young child is *naturally* a tyrant, and will reduce all around him, if possible, to be the slaves of his desires. The problem of moral education, accordingly, here is to reduce this lawlessness with which self rises up to assert its power into a willing obedience to order and discipline,—an obedience which shall not arise from the crushing effects of sternness and severity, but from the feeling, steadily inspired, of the *absolute power of a command*. Willing obedience to a categorical imperative is the first great lesson in our whole moral life, and un murmuring deference to the will of a parent or teacher is the natural preparation for our subsequent unwavering deference to the moral law of God.

As the mind grows, the tone of *authority* in the teacher must gradually *relax*, and justify itself by an appeal to the intelligence and moral sense of the pupil. In this way the respect for authority is increased by associating it with what is reasonable and just. Moreover, when the understanding becomes mature, even then a great deal must still be inculcated on the authority of the teacher, inasmuch as the logical faculty does not give us the power of penetrating into the grounds of human conviction. But respect must now be paid to the personality of the pupil, so far that the self-consistency of truth must always be made apparent, and nothing inculcated that could in any way militate against the moral intuitions. By this process the habit of self-control may be nurtured into a fixed principle; the power of acting according to established maxims of right may be strengthened; so that when the man becomes mature, and is thrown entirely upon his own guidance, he will respond to the moral convictions which have been formed, and expresses in outward action what the conscience inwardly affirms to be *good*. This self-control of the will becomes, of course, so much the greater in proportion as the convictions of conscience are shown to rest on a Divine and infallible foundation; and it is just here that moral education connects itself with religious training, which is indispensable as giving a firm and immovable basis to the whole. We have now glanced at the three main branches of human education—the physical, intellectual, and moral. There are yet two other branches, which grow out of those already treated of, and which regard the man not so much in relation to the development of his inward powers, as in relation to the circumstances by which he is surrounded and the destiny to which he is tending.

4. The first of these is what we have already noted as *Political education*. Much of the political education of a

people is of course *spontaneous*. It is only *gradually*, and by the training of long experience, that nations acquire the power of self-government, and that the individual finds his own position, politically speaking, in the community. There are, however, many things of great importance to the citizen of a free country which *can* and *ought* to be taught,—the want of which, moreover, is fraught with serious evils both to the individual and the state. These are, the nature and functions of government, the obligation every man is under to yield a portion of his personal liberty to the public good, the duty of obeying all the just laws of the community, the nature and rights of property, the relation of capital to labour and of the employer to the employed, the laws of the production of wealth, and the ethics of commerce. The want of some elementary knowledge on these matters naturally gives rise to sedition, conspiracy, and revolution on the one hand, or to misery, pauperism, an

National
Education.Religious
education.

consequent vice and degeneracy, on the other. Every child, therefore, should be trained to know and act upon the fundamental ideas of social economy and the primary duties of citizenship.

5. Lastly, *religious* education must give the crown and glory to the whole,—its great object being to supply a Divine sanction to all the dictates and requirements of our moral nature. Religious education, properly so called, begins in the development of the sense of the Infinite and the Divine,—deepening the consciousness of an ever-present and an almighty Being, who sees, rules, and guides all, and takes cognisance of human actions, whether they be good or evil. It next goes on to explain what means we have of knowing the will of God, whether manifested in nature, or, more directly, in revelation. And, finally, it should sum up the whole of the truths or principles thus elicited into a compendium of religious faith and practice which may serve the purpose of a succinct system of theology. The first of these processes is adapted to the child, the second to the youth, the third to the human mind in its full maturity. To teach the Catechism *to a child* is beginning at the wrong end, and holding up the truths of theology to him in their most abstract form before the power of abstract thinking is at all consolidated. Religion must be inculcated first in the intuitions and feelings; then it must occupy the memory and imagination; and, lastly, it must live in the understanding and the reason.

Regarding the present state of European society, it can hardly be affirmed that any individual is regarded as an educated man who has not experienced some amount of training in each of the departments above described. Every educated man must at least have gone through so much physical training, either consciously or unconsciously, as to give him a deportment proper to society, and a power of articulation sufficient to express his thoughts with intelligence and propriety. He must have had his perceptive powers so far cultivated as to observe what passes around him intelligently. He must have acquired some strength of memory, some power of conception, and the correct use of his native language, whether in writing or speaking. Further, the *understanding* must have been so far developed that the mind can generalize to some extent,—see the relation of one truth with another, and draw correct conclusions wherever the data are plain and obvious. With regard to *moral* training, the will of every educated man must be under some control, so that it can hold in check the lower passions and propensities; for the want of this is one of the chief features of barbarism. Politically speaking, education must enable every man to fill his place honestly and creditably in the station which he occupies in society, whether it be higher or lower. And, finally, it must have made him so far acquainted with the ideas, sanctions, and duties of religion, that he knows and appreciates its obligations as they are held and enforced in that particular community to which he may chance to belong.

This, perhaps, we may regard as the *minimum* of what is requisite to form *an education* in the present sense of the word. It may seem, perhaps, to include a great deal, especially when we consider how much actual instruction must be employed in order to bring the mind even into a moderate state of discipline upon all these points; and yet a decided failure in any one would inevitably cause any man among us to sink below the level of what are termed the educated classes of society. No system of national education, accordingly, could possibly contemplate less than we have now stated as essential to the present idea of an educated man. Every citizen, at least, in a free country, should have the means of mental development *so far* put into his hands. The expansion of the idea of education into its higher aims and purposes belongs, of course, to the higher spheres of instruction, and will always be determined in its

amount and its character by the progress of knowledge and civilization through every succeeding era of human history. National Education.

We come now to the more practical aspects of the subject, and have to inquire,—

II. WHO ARE THE PERSONS AND WHAT THE AGENCIES BY WHICH NATIONAL EDUCATION IS TO BE CARRIED ON?

There are a thousand agencies that really bear upon the education of a people, which cannot be distinctly enumerated or calculated. Human life itself is an educating process, and much more so in some countries than in others. The active life of commercial towns has a more stimulating effect upon the minds of the people at large than the quiet routine of agricultural pursuits. In countries, too, which possess free institutions like those of England or America, the intercourse of daily life presents far more to stimulate the energies and educate the whole man than the monotonous political atmosphere of absolute governments. Hence we sometimes find that a country with very complete educational institutions does not produce nearly as much mental vigour, practical energy, and bold enterprise as another country where the actual institutions are perhaps far less complete, but where the stimulus of daily life is much greater.

(1.) The question which we have now to discuss, however, does not relate at all to this spontaneous education, which lies, in fact, beyond the direct control of human agencies. What we mean by the problem now before our consideration is, who is to frame, superintend, and carry on the actual educational institutions of a country? On this point various theories have been propounded, the principal of which must be now briefly considered.

1. It is urged that education should be left to its own natural development; that the demand for teaching will of itself create a supply; and that the result of this natural supply will, in the end, be superior to any kind of education which is more artificially constructed. Supply and demand system.

Now, there can of course be no doubt but that, amongst many different peoples, education will make considerable advancement when left to its own natural course of development; but it would be taking a very narrow view of the laws of human progress to elevate this into a principle which could not be deviated from without danger and detriment. In all the different spheres of human activity the impulse afforded from time to time by some great master-mind appears to be one of the most natural and universal agencies by which human progress is secured. And this is not only true respecting the advancement of science, literature, or philosophy; it is equally true in regard to political development and social reformation. Take the case of Alfred the Great in our own country. Here is an enlightened sovereign, with knowledge and foresight far beyond his times, who is called to rule over a people only just emerging from semi-barbarism. Applying his superior abilities to the wants of his people, he not only makes wise laws, and lays the basis of useful institutions, but seeks to promote education by founding colleges and schools of learning similar to those of which he had himself had experience on the continent of Europe. It certainly could not be said that this was of no benefit to the country; that the people should have been left to find their own way out of the surrounding ignorance; and that everything done for them by the legislator, except what related to physical order and security, was an error and a mistake. Or take the case of Peter the Great, when he had the design of raising Russia into the sphere of civilized nations. To have affirmed in this case the principle, that because Peter was emperor, and invested with governmental authority, therefore he should not, on principle, interfere with the ignorance of his people, or move a single step in the pathway of their education, would assuredly be narrowing down the functions of great rulers and great

National
Education.

legislators to a very subordinate degree of importance in the march of human progress,—a degree not at all corresponding with their natural and providential position as great reformers. If these and similar instances, then, be admitted as cases in which the interference of legislators in the educational institutions of their country was good, useful, and even necessary, then the principle of supply and demand, as a universal law, breaks down in its application. Many nations, as we see at this moment, left to the working of this principle, have failed to elevate themselves at all out of the ranks of barbarism or semi-barbarism; the *demand* for education in their case never appears, and thus there is a total lack of the *supply*. If there be any truth in history, an enlightened governor or government can assuredly do much to bring some useful agency to bear upon a people living or vegetating in this unsatisfactory and undeveloped condition.

Suppose, however, that a nation has already been raised into a civilized state, the question is, can we not then safely leave its further educational progress to the principle of supply and demand? The term civilization, it may be replied, is a relative one. It is difficult to say when a nation, viewed as a whole, is really civilized, and consequently difficult to draw the line where educational progress can be safely and properly left, if at all, to self-development. Civilization does not equally pervade all ranks of the community; and we find universally, that even in the bosom of the most advanced countries there is a large class of semi-barbarians who prey upon all the rest. Here, then, we have a case in which the *demand* for education is least where the *want* is the greatest. The principle of supply and demand does nothing therefore directly to elevate them; and the question comes, whether society is to wait patiently, and bear all the social ills resulting from these seething beds of ignorance and vice, uncertain whether the desire of reformation will ever manifest itself, or whether a wise form of legislation may not do much for their reformation, and thus aid in preserving others from the moral contamination. Whatever principle be adopted, government cannot hold itself disconnected from these lower strata of society. It is obliged to watch them, to intimidate them, to repress them, often to imprison, prosecute, and punish them; and the idea naturally suggests itself, whether in such a case it would not be wiser and better, as well as cheaper, to attempt some educational means of reformation, than to be ever engaged in a perpetually renewed struggle of force against force. Of all the countries of Europe and of the world, Great Britain can lay, perhaps, as valid a claim as any to the merit of being in a state of civilization. But no one can deny, that education, so long as it was left to the principle of supply and demand, continued in England to be in a lamentably weak, insufficient, and unsatisfactory state. The first extended efforts to amend this state of things, moreover, did not arise from any outcry or demand from the people themselves, but from the philanthropic efforts of individuals and societies; and these efforts, further, only began to rise into large proportions, or to meet any considerable amount of the acknowledged want, when they were seconded and upheld by governmental agency.

Scotland, again, which has always maintained a superior standing in respect to popular education, owes this superiority mainly to legislative enactments at the time of the Reformation (followed up by the Act of William III.) which provided the means for keeping up one school at least in every parish throughout the country; while Ireland, where no such enactments were made, has remained in a state of ignorance, and almost barbarism, which is only now being broken down by the active co-operation of government in the education of the people. And what is true of the lower is equally true of the higher education of these countries. Universities in these, as in most other countries of Europe,

National
Education.

have not sprung up, or if they have done so, have never attained any large proportions, when left to the natural operation of supply and demand. For although many of them rest on private foundations, yet it is only when they attain the character of national institutions that they seem to combine the advantages requisite to produce seats of learning, in which leisure and opportunity are afforded for the due cultivation of the higher walks of literature and science. Individuals of course there will always be, whose genius breaks through every obstacle, and urges them forward to eminence, even from the very lowest ranks of the people. But the higher culture of a country could not be left to depend upon the irrepressible genius of the favoured few. What is wanted to make it tell upon the progress and welfare of the whole community is a steady maintenance of institutions in which learning may be cherished on a large scale, and its influence then diffused throughout the whole community. In this point of view national universities, even though often fraught with abuses, have played the most important part in the history and development of every country in Europe. With these facts before us, we conclude that it can hardly be the course of wisdom and prudence to leave the social evils arising from ignorance untouched, and trust to a mere theory, that at some distant period society will right itself, and education become spontaneous.

2. This leads us to a second theory, namely, that the state should hold the education of the entire community in its own hands, as being the natural guardian of the welfare of the community. This theory may be regarded as the opposite extreme to the former one; and if that is open to objections, this in its turn is no less open to them also. First of all, it may reasonably be objected, that when education is wholly in the hands of the government, it may be employed for state purposes, instead of being adapted solely to the benefit of the community. This objection is not a mere speculation, but is one which may be largely borne out by facts. If we take any of the more despotic countries of Europe as examples, it is hardly to be denied that the public instruction of the people is so arranged, or so limited in its material, as to favour the interests of the monarchy rather than the free development of the mind of the people. The Metternich policy in Austria may be quoted as a well-known and universally-acknowledged example of this. Everything was done during its prevalence to enhance the material comfort of the people, and to nurse them in the lap of physical enjoyment, while the most rigid care was taken to exclude the entrance of progressive ideas, and to prevent the popular mind from ranging beyond the wants and enjoyments of the hour. In countries like Prussia, where the force of public opinion is strong enough to control the acts of the government, education naturally attains more freedom and strength; but even here it is conformed pretty closely to the state policy of the time being, and scarcely attains the elasticity which it would do under a more popular system. This is especially visible in the middle and higher education of the country. In spite of all the admirable organization which the Prussian educational system affords, from the people's schools up to the university, yet the fact of all the places being virtually in the hands of the crown, which thus holds in its keeping the destiny of the entire mass of gymnasial teachers and university professors, exercises insensibly an influence upon the minds and opinions of the great body of the learned men of the country, and biases them towards the views and the general policy of the government. Even the current systems of philosophy are not a little determined by the direction in which the sunshine of court favour falls upon the processes of human thought.

It might, however, be a question how far this objection against a purely governmental system of national education is obviated by the fact of a government becoming popular,

National
Education.

constitutional, and free. This introduces, no doubt, another phase into the whole aspect of the subject, but does not altogether render it free from the same difficulty. In a country like England society is divided into various large communities, distinguished from each other by their religious peculiarities, or by their social habits, or by their political sympathies. All these will have their own special views respecting the nature and machinery of popular or other education, and will exercise a pressure upon the government upon this as well as upon all other questions. Now, a constitutional government, we well know, can only maintain its position at the head of affairs by enjoying a certain amount of popular sympathy and support. Hence, instead of taking up the question of education simply as a question of national advancement, it is inevitably regarded also as an element in the state policy. To go contrary to the views of this or that large community might endanger the majority at the next election; and so a course must be steered between conflicting objections which shall satisfy the largest number and give the least offence. Thus a question like national education, which ought to rest simply and solely on the higher ground of the good of the people, irrespective of all political tendencies, when once it is centralized in the hands even of a constitutional government, becomes inevitably mixed up more or less with party struggles, and is treated with a view to majorities and minorities like any other question of state polity. Whether, therefore, we regard education as centralized in the power of the crown, as in the case of a despotic country, or as centralized in the bureau of a government, as in the case of a free and constitutional country, in both cases alike there are obstacles which stand in the way of a purely beneficent system, altogether removed from political or party interests. Of course the evils may be greater in one place and less in another; but, theoretically speaking, the centralization of all education in the hands of a government, whether constitutional or not, can hardly be separated from a certain amount of concomitant evil or imperfection.

Education
by the
church.

3. A third theory of national education is, that the church should educate the people. This is one of those theories which is rarely taken up upon universal grounds either of right or expediency, but is usually advocated by those whose views and sympathies are confined to some peculiar form of religion or of church polity. Moreover, those who advocate it as regards themselves would very rarely admit the soundness of the principle as applied to countries of a different faith and practice. In some Catholic countries, where there is nearly an entire uniformity of faith amongst the mass of the people, the principle that the church is the proper educator of the community has been oft-times affirmed, and to a large extent acted upon, under the sanction of the governments. But in other countries where a Protestant church establishment exists, the Catholics are very far from admitting the principle that this said Protestant established church should be entrusted with the whole work of national education whenever it becomes predominant. Neither do the Protestants, in their turn, who advocate the principle of church education in regard to themselves, show any greater disposition to carry out the principle when it would throw all education into the hands of hostile communities. The idea, therefore, that the dominant church should be the sole educator of the people, however simple it may appear as a theory, yet entirely breaks down in practice. There was no doubt a time in the history of Europe in which this theory might have been actualized—the time, I mean, when there was one complete uniformity of faith, when the church stood virtually on a level with the state, when the whole of society was based as much upon ecclesiastical institutions as upon civil government, when the see of Rome affirmed for itself a universal spiritual sovereignty over the human mind, and

National
Education.

the clergy were the only depositaries of knowledge, small as it then was. But these times have long passed away; and it is only the lingering memory of such a state of things in the minds of those who live more in sympathy with the past than in the realities of the present, that could possibly keep up the illusion that this principle is in the slightest degree applicable to the time in which we now live. In the present day learning and science have become quite independent of religion, or at least of religious institutions. Each sphere of human activity, the religious and the secular, pursues its own way and reaches after its own results. Society, too, has at the same time become removed from an ecclesiastical to a secular and politico-economic basis. However faithfully the individual may cultivate his religious life, society as a whole is bound together by civil law and social customs, and can only act as one personality upon these general principles. Hence to speak of society as placing its own education in the hands of the church, would be simply giving up to those who represent the religious principle a function from which that principle is already virtually divorced. The church is not in any way scientific in its basis; it does not represent the learning, the science, the philosophy, the progressive ideas of the age. The general tendency of it in this point of view is frequently retrogressive rather than not; it has to be urged on by the spirit of the age more frequently than to guide and correct it; and whenever it has the control of educational establishments, it is not unfrequently engaged in a struggle to keep them to their ancient forms and spirit; while the age is equally struggling to develop them into new and more progressive institutions.

Hence the church is, *in fact*, educated by the people far more than the people by the church; so that to affirm the principle of church education uninfluenced, except permissively, by the state, would simply be to put one series of institutions and agencies in constant conflict with another. The church has its own sphere. It represents the religious interests of mankind; it has to keep alive our faith in the spiritual and eternal amidst the hurry and bustle of human life; it has to bring the aids, the motives, the consolations, the impulses of religion to the mind of a people too much immersed in secular concerns; but it can no longer seat itself on the throne of learning, or science, or of popular education; for the whole tendencies of the age are to make the separation of these things, already sufficiently wide, more and more absolute. The term church, however, is indefinite. In no countries where any amount of independent thinking has sprung up, does the religious life assume one uniform aspect. In England, according to the last census, fully one-half of the whole church-going population of the country was found to attend places of worship belonging to the various unestablished religious denominations; and in Scotland and Ireland the established churches are both greatly in the minority. Under such circumstances, of course, the theory that the church should educate the people could only be for a moment entertained in the broader sense, that the education of the country should be left in the hands of the religious bodies, to carry it on by their own voluntary activity. That a certain amount of healthy philanthropic effort may and does develop itself in connection with religious bodies in relation to the education of the people, facts abundantly prove; but it is one thing to allow this activity its free scope, and another to leave to it the entire education of the community. As far as our present experience goes, the voluntary efforts of religious communities, though they have effected much good in their own immediate circle, yet have totally failed, when left to themselves, to assume anything approaching national proportions. The very nature, too, of voluntary effort in matters of this kind is fluctuating and spasmodic. It can do much under sudden

National
Education.

excitement; but it always diminishes and grows feeble when excitement dies away. Thus in matters which require one steady unwavering flow of support, quite independent of any kind of public incentive, voluntary effort always shows itself incompetent. Such incompetence may be of little moment in some branches of philanthropy; but when we consider the vastness of the scale on which national education must be carried on in order to be effective; when we consider the immense amount both of money and machinery which is requisite to keep it going steadily forward, reaching all the farthest recesses of the country; when we consider, moreover, the tremendous stake which a country must always run in deciding the manner in which the masses of the people are enlightened and trained in early youth, it cannot assuredly be wise to leave the whole to what have hitherto proved, in every country in the world, uncertain, fluctuating, and wholly incompetent resources.

Moreover, religious bodies are themselves exposed to revolutions. New ideas spring up, new forms of doctrine appear, wide-spread disputes prevail, vast schisms and disruptions disturb from time to time the working even of those bodies which are apparently the most firm and unmovable, and draw away public attention and public effort from all the details of denominational life. In the midst of all this, however, the people, with its wants, its ignorance, its need of proper training and enlightenment, whether in the purlieus of the city or the remotest nooks of the country village, is a standing fact, which cannot be abandoned with any security to the mercy of these fluctuations. So far, then, there is an objection to the principle we are now considering in point of *fact*, but there is also an objection in point of *theory*. It will hardly be maintained by any one that the rivalry and social separations of contending sects is a *benefit* to the community. Even when confined to religious differences, it produces ill-will, unhappy feeling, bad neighbourhood, and want of unity amongst citizens in carrying out social changes or much-needed reformations. Should the education of the country, however, be left entirely in the hands of the religious denominations, this separation, which was before confined to acts and forms of public worship, must gradually sink down lower into the core and heart of society. Denominational distinctions would begin with the child in the school; his sympathies would be confined to his sect from his youth up; and the whole country, as far as it was educated at all, would grow up stamped with certain *intellectual* types, which would add tenfold intensity to the *religious* ones. To sum up, then, in a few words, the objections to the whole theory, we should say that it must, first of all, fail in reaching the far-spreading wants of what we mean by national education; secondly, that it must prove defective in yielding steady unfluctuating support; and thirdly, that, so far as it does extend, it has the undesirable effect of perpetuating and intensifying the spirit of sect throughout the country.

Education
by church
and state
conjointly.

4. A fourth theory of national education, which is simply a combination of the second and third, is, that the state should educate with and through the church. In countries where the established church represents the uniform faith of the people, this principle might work in many respects advantageously. The church being here co-extensive with the state, and possessing already a complete territorial system of arrangements, adapted to and sympathized in by the whole population, it seems at first sight to be a matter at once easy, convenient, and economical to employ the church agency through the length and breadth of the land to conduct and superintend the *educational* agency; though of course under state control. The same objection, however, lies here as we before urged in relation to a purely church education; namely, that the church is not constituted upon a scientific basis, and from its naturally conservative tendencies is apt, in some cases, to come into collision with

National
Education.

the advancing educational tendencies of the age. The more the fact becomes realized that the church has a spiritual function of its own, the less will society be disposed to encumber it with social duties which will hinder its own legitimate activity, and only be imperfectly performed after all. This theory, however, can only be entertained at all in countries where the religious faith is uniform: in countries like our own, where this is not the case, the only application of it would be one in which the government co-operated with all the religious bodies, and assisted them equally to carry on the work of popular education. This system, however, has the double disadvantage,—*1st*, Of investing spiritual bodies with a civil and political function; and *2dly*, Of putting into their hands additional means of maintaining their own denominational peculiarities through the popular school. It is a matter not at all denied or concealed, that religious bodies who take up the cause of popular education do so not simply and solely for the benefit of the community, but equally for the benefit of their own denomination, and to spread its influence more largely throughout the country. Hence the school becomes a kind of appendage to the church; education is viewed with respect to church purposes, and a system of antagonisms which has grown up in the religious life of the people becomes *doubled*, by having an educational as well as an ecclesiastical arena on which the combat may be carried on. All this is of course much modified and softened by state control, but by no means obviated, as we shall have occasion to observe in the case of our own country.

We are now reduced to a last and fifth theory of education, viz., that the state should undertake it *through the people*. According to this plan, the government provides that the country shall be divided into certain districts, that in each district a competent board shall be elected to manage the educational affairs; that a sufficient rate shall be raised to support the necessary schools, and that the local authorities shall thus co-operate with the central government in giving vigour and efficiency to all the institutions which may be originated for the instruction of the country. Of course the details of such a system will be very different in different countries. In some, the central government will have a greater preponderance; in others the local board will exercise the principal functions; in others, again, the principle of voluntary effort may come in as a portion of the whole plan; but in each case the fundamental idea is the same—that of the union of the people, in their capacity as free citizens, with government, in the institution and superintendence of popular education. Whatever difficulties this plan may in special cases have to encounter in its course to a practical realization, yet, *as a theory*, it stands pre-eminently above all the rest. It has none of the partial character about it which is inseparable from the idea of leaving education to fight its own way, but goes directly to the root of the question, and aims at complete measures for meeting the wants of the case. It equally avoids the opposite evil of centralization, and, by creating a local authority, places the educational institutions of a country in a position where they cannot be made part and parcel of the machinery of government. Again, it contemplates the wants of the people, not through the peculiarities of any particular religious system, but by the light of reason and common-sense, as expressed by the spirit of the times; and as it stands apart from religious dissension, it can adapt itself to all the circumstances which the future history of a country may bring into existence. As a theory, moreover, this has already received the stamp of practicability both in America and in some of the British colonies; and in no new country probably, where free institutions exist, would any other system now be ever maintained or even attempted. In old countries like our own, the pathway to such a system is not so clear or so

National
Education.

feasible; but all the changes which are introduced naturally tend to this as the final result.

Looking to the relation which the parent holds to the teacher in the above-mentioned system, this, of course, will be different in each. *1st*, In the case of education being a question of supply and demand, the parent stands simply in the position of a *purchaser*, who gives a certain price in the market for value received on the part of his child. The whole is simply an ordinary commercial transaction. *2dly*, When the government provides education and takes any means to enforce it, then the parent stands to the teacher in the relation of a subject of the realm to one who administers and carries on a national institution, and has no power of complaint or appeal so long as he administers it according to principles laid down by superior authority. *3dly*, Where the *church* provides education, the relation of the parent to the teacher is that of a member of a religious community to the government of the church to which he belongs, and his appeal, in case of dissatisfaction, must be simply to the church authorities. *Lastly*, When the people provide education in their capacity as citizens, the parent stands to the teacher in the relation of a unit in the local community to any municipal officer who carries out the will of the whole. The first relation is a *commercial* one, the second a *civil*, the third an *ecclesiastical*, the fourth a *municipal*. In the last case the teacher is a citizen who is entrusted by his fellow-citizens with a certain duty, which he is able to perform more satisfactorily than themselves. In other words, a portion of parental duty is given up to one who devotes his whole time to do *well* what the parents individually would do very imperfectly, or not at all.

Educa-
tional
agencies
actually
existing.

(2.) Having gone through the various *theories* which have been propounded as to the proper agencies to be employed in carrying on the work of national education, let us now view the question as a *matter of fact*; and inquire who actually *do* educate the people in the most civilized countries of the world, and what are the agencies which really *are* employed for this purpose. A clear statement of the actual facts of the case may tend to throw considerable light on the working of the different theories already explained.

Prussian
education.

The country which has usually been held up as having the most complete and thorough-going system of national education is Prussia. It may be as well, therefore, to begin by giving a brief statement of the principles and some of the details of the Prussian educational system. And, first of all, I should premise that the question of national education has been viewed in Prussia not in relation to one portion, but in relation to the whole extent, of the community; not in relation either to elementary education alone, but in relation to superior and university education as well,—the whole forming one graduated system adapted to all classes of the people. The basis of this system is purely governmental; the centre from which it all emanates being a minister of instruction immediately dependent on the crown.

The entire instruction of the country is divided into three main departments:—*1st*, The universities; *2d*, The high schools or gymnasias; and, *3d*, The primary schools, including those adapted to the village, and the somewhat superior ones which are intended for the towns. For conducting and superintending these different classes of educational establishments a considerable machinery is put into operation, of which we must next give some general idea.

The kingdom of Prussia is divided into ten provinces, *viz.*,—Eastern Prussia, Western Prussia, Posen, Pomerania, Brandenburg, Silesia, Prussian Saxony, Westphalia, Cleves, and Lower Rhine. Each of these provinces again is divided into districts (*Regierungs-Bezirke*); each district is

divided into circles (*Kreise*); and each circle into communes (*Gemeinde*). These divisions, which subserve the general purposes of government, are also taken as educational divisions, and form the geographical basis of the whole superintendence.

National
Education.

First, with regard to the provinces. Most of these possess a university. The superior direction of the university is in the hands of a commissioner who belongs strictly and solely to the government, so that the entire administration of the universities is governmental, not being interfered with in any way by local authorities, either civil or ecclesiastical. All the laws and regulations affecting them, as well as all the appointments of professors, emanate directly from the crown.

Next, in regard to the high schools or gymnasias. The direction of these is placed in the hands of the *provincial* authorities. Each province possesses a consistorium, which is charged with the affairs of the church, the school, and the public health. That portion of the consistorium to which the affairs of public instruction are committed is termed the *Schul-collegium*, each member of it being appointed and salaried from the crown. The members of the consistory who administer ecclesiastical affairs are all clergymen; those who administer the educational affairs of the province are all *laymen*, so that the educational and the ecclesiastical elements are kept *quite distinct* in high quarters, and can there never come into collision. The basis of the Prussian system of education, it will be seen from the above explanations, is wholly civil; its connection with the church being only seen in those minor details to which we shall have soon to refer. Just as the administration of the universities emanates from the central government of the country, so does that of the high schools or gymnasias emanate from the *provincial* government, which makes all the appointments, and keeps a board of examiners sitting in perpetuity, at once to test the capacity of the teachers, and the proficiency of the students previous to their being drafted off to the universities.

Thirdly, with regard to the primary schools. The direction of these is made over to the smaller divisions of the country; that is, to the departments, the circles, and the communes.

Every commune is bound to have at least one primary in or near it; and every child of that commune within a certain age, whose parents cannot show that he is otherwise efficiently instructed, is bound under certain pains and penalties to attend it. Accordingly, both the means of education and the obligation to use them are carried out strictly throughout the entire length and breadth of the land. In order to maintain these schools, care is taken first of all to manage and properly appropriate all the old school funds and charities, of whatever kind, and put them to their proper use. Next, all the land proprietors and fathers of families in the village form a school constituency (*Land-schulverein*), upon whom it is incumbent to raise sufficient funds, by means of an equitable tax, for keeping the school in an efficient state after all the school endowments and school fees have been taken into account. If in any case the poverty of the commune renders this impossible, then the additional funds required must be made chargeable upon the whole department. In larger parishes and in towns schools of a higher order (*Bürgerschulen*) must be maintained, according to the wants of the population, which are supported virtually in the same way as the small country schools.

The *management* of these institutions is organized in the following manner:—In every village a committee is formed, consisting of the patron of the church (if any), the clergyman, the local magistrate, and some two or three of the principal inhabitants. These are called the school-presidency (*Schul-vorstand*). In towns or places where there are churches of different communions, the clergyman of

National Education. each communion is to be on the committee; and in larger places still, where several schools exist, there is a school commission appointed to manage the whole.

A complete system of inspection also exists. The clergyman of the commune (or clergymen of each communion, where more than one exists) is nominated *ex officio* the local visitor. In every circle, however, there is an official inspector appointed by the provincial government, who is generally an ecclesiastic, either Catholic or Protestant, according to the preponderance of the population. Thus, the two authorities which come nearest into contact with the children are the ministers of religion; and this is considered to be the best guarantee for keeping up the strictly religious character of primary education. After this, however, all clerical influence ceases, and is never admitted in any way into the higher administration.

The next higher authority, after the district inspectors above alluded to, is the *Schulrath*, who is, in fact, the minister of instruction for each department (*Bezirke*), and forms the link between the local school committees and the provincial government. Very little of the direction of the schools, and none of the legislation, is left in the hands of the local managers. All they have to do is to carry out the orders of the superior authorities, and find the necessary funds. They retain, however, a voice in the appointment of teachers, but must not interfere with them as to the manner in which they discharge their duties, or the methods of instruction they follow. The government takes care that *all* the teachers shall have a sufficient normal school training, and obliges them to pass an examination, and hold a certificate of competence, before they can be chosen as teachers at all. When, therefore, their appointment is once made, it is presumed that they *understand* the details of school organization and method better than those who have not been trained for the purpose. Accordingly, although the Prussian primary teacher is but poorly paid, yet his position is independent, and his superior education always entitles him to hold a respectable rank in the society amongst which he is placed. Every appointment of a teacher, moreover, as well as every dismissal, must be known and ratified by the provincial government.

In the year 1846 the number of educational institutions in Prussia, according to the official tables, was as follows:—

Elementary schools...	23,030
Bürger schools	1,202
Higher town schools	100

making a total of 24,332 *primary* schools, with 2,540,775 pupils between the ages of 6 and 14. To these must be added 117 gymnasia, with 29,474 pupils, all enjoying a sound classical training; and 382 infant schools, with 25,000 pupils. The population of Prussia in 1848 was about 16,000,000, comprehending about 3,000,000 children between the ages of 7 and 14. Of these, about 2,600,000 were actually in the governmental schools, leaving only 400,000 to be accounted for by private education, sickness, and other unavoidable causes. There can be no doubt, therefore, that the Prussian people are really educated throughout the whole community, and educated, too, according to their relative stations in life, with decided efficiency.

From the above sketch we can easily see that the department of public education in Prussia forms a most complete and all-embracing system, emanating entirely from the government, and responsible to the government for all its acts. All the questions which form stumbling-blocks and difficulties in our own country are summarily disposed of, because the idea of the *state* dominates over every other, and all private interests or opinions are made to bend to this as the governing principle of society. Much of the burden is borne directly by the government, such as the cost of the universities, and partly also that of the gymnasia and normal schools; but no difficulty is felt in making all

property rateable, and imposing it as a duty upon every parish to see that sufficient education is provided for the children of the commune. The advantage, indeed, of sound education being brought within the reach of all for so trifling a fee, makes any disposition, which there might otherwise be, to complain of the burden wholly unreasonable.

Again, education being provided *for* all, the law compels that it should be embraced *by* all; and thus all the apparatus of motives for inducing attendance is obviated, and the whole question of early removal from school settled by an authority from which there is no appeal.

The religious question is settled with the same ease. Respect is had for differences of faith. The master is usually appointed in accordance with the religion of the majority of the people; and if there be any considerable number of inhabitants of different communions, separate schools for each are rather encouraged than not. Where this cannot be the case, it is usual to appoint the second master from the communion of the minority. No religious instruction is ever given to any of the scholars except by a teacher belonging to their own denomination; and parents have absolute permission to withdraw any of them from religious teaching which is opposed to their professed convictions.

Whether this formal and governmental religious teaching has had much real effect in cherishing the religious faith of the people is much to be doubted, if we may judge by the results; but no one can doubt the vast effect of the system *as a whole* in encouraging learning, and raising up an immense body of highly-educated men.

We ought, however, here to make a distinction between learned men and men who have the power of applying their learning to practical objects. With all its vast amount of *learning*, Prussia does not take the lead in enterprise and civilization generally. "It is sometimes asked," says Horace Mann, "why the Prussians, with such a vast and powerful machinery for popular instruction, do not as a nation advance more rapidly in the path of civilization; why the useful and mechanical arts among them are still in a half-barbarous condition; why the people are so little enterprising; and finally, why certain national vices have not yet been eradicated. . . . The chief cause," he concludes, "of the helplessness and incapacity of the Prussians is this. When the children once leave school they have very few opportunities of *applying* the knowledge, or *exercising* the capacities, which have been acquired and developed there. Their mental resources are not drawn upon, their capacities are not quickened or strengthened by practice. Phrases such as "the active duties of life," "the responsibility of citizens," "the stage or career of action," "obligations to posterity," which are in common use amongst us, would have a foreign sound in the ears of a Prussian. In Prussia the government takes about the same care of the citizen as the citizen takes of his cattle. The citizen does not elect functionaries, is not called upon to inquire into the character or eligibility of candidates for office, has no vote to give. He neither makes nor repeals laws. He is not called upon to discuss or decide questions of peace or war, of finance, customs, taxes, or postal and internal arrangements. He is not asked where a road is to be opened or a bridge to be built, although in the one case he has to furnish the labour, and in the other the materials. His sovereign is born to him. The laws are made for him. If there be question of war, he is not called upon to account for it or to end it; he has merely to fight, to be shot, and to be paid. The tax-gatherer tells him how much he has to pay in taxes; the ecclesiastical authorities draw the plan of a church which he is made to build; and his spiritual guides, who have been appointed by others, prepare a creed to which he has only to subscribe. He is told in the same way how to

National Education. obey his king, and how to worship God. But although an ocean slumbers in the mind of every child that is born, what will prevent its eternally remaining in a state of gloomy stagnation, if no refreshing, quickening breeze be allowed to stir over its surface."

This is probably a correct account of the fundamental weakness of the whole Prussian system. Education does everything for the people that could be expected, but education *alone* is insufficient to produce practical energy. This can only be done through the influence exerted by political liberty and popular institutions, which open an independent course of action for every citizen of the country.

In giving the above sketch of the state of national education in Prussia, we have in fact before us, with minor modifications, a general idea of what exists throughout all the different states of Germany. German education, therefore, as a whole, may be pronounced purely governmental, complete in its organization, and productive of a vast amount of intellectual culture. It is open, however, to grave doubts whether it produces fruits equally good in relation to the practical energy of the people, to their moral habits, and to their religious faith. These last results appear to depend upon causes operating in the national mind, in the social habits, and in the religious life of the people, quite distinct from anything which can be secured by a governmental system of education, however complete both in theory and practice.

Dutch education. Holland is in many respects different from Germany. It has been more under the influence of popular institutions, and had some apprenticeship to the art of self-government. The general features of the national education of Holland bear the stamp of this. They are less minutely defined and regulated by the central authority than those of Germany, —less under the direct influence of the state,—and are thrown more into the hands of local managers. The only officer of the state who has anything directly to do with public education is the minister of the interior, together with a *referendaire* and one head inspector. This forms, in fact, the whole amount of centralization which exists in the system. All the other functionaries are quite distinct from either the civil or municipal authorities. They consist chiefly of district inspectors, appointed by the government, who have almost the absolute direction of the educational affairs in their hands, each being a kind of educational plenipotentiary in his own district. These inspectors, moreover, hold a convention from time to time, and thus form a kind of educational parliament, in which all the affairs of the country relating to public instruction are duly discussed. In addition to the inspectors, there is a committee of management in each town or school district, who act in concert with them, but are quite distinct from the municipal officers of the country.

All the details of primary education, in fact, are left in the hands of the inspectors; neither is any precise *mode* of rating imposed upon the townships in support of the schools, except that they must confer with the inspectors, and raise sufficient funds in any way that appears most suitable, in order to keep up the institutions in an efficient state.

Another peculiarity of the Dutch system is the mode in which the religious question is solved. As Holland contains a considerable number of religious sects, it was considered undesirable to provide religious instruction in each school, according to the denomination of the children. Instead of this, it was determined not to introduce any catechism, or distinct dogmatical teaching at all. They reasoned very judiciously, that children are unable to distinguish between different dogmatic systems; that the inculcation of them during their daily lessons is not only unnecessary, but unadvisable; that it is much more suitable, in fact, for children in the day-school to have a good knowledge of holy Scripture given them, together with an earnest inculcation of Christian duty, accompanied with simple

National Education. devotional exercises, than any more direct dogmatic teaching. As other agencies exist in the country for the direct teaching of theology, it was thought that the children might be safely relieved of this during the ordinary hours of daily instruction; so that the difficulties connected with variations of doctrine in connection with the primary school might be avoided *ab initio*. Hitherto no inconvenience is believed to have resulted from this principle, nor are the children any less inclined to Christian doctrine in after life from its not having formed any part of the *daily routine* of the primary school. Taking it altogether, the public education of Holland may be regarded as fully equal in efficiency to that of Germany, —in some respects, indeed, superior,—and the number of children actually found in the schools shows that although the attendance is not compulsory, yet almost the entire population is really educated.

We come next to France. Here, as in Germany and French Holland, the plan of public education is threefold, comprehensive, *1st*, The universities; *2d*, The colleges; and *3d*, The primary schools. The universities are divided into five faculties,—namely, theology, law, medicine, science, and literature. Each of these faculties can exist apart from any of the rest. Thus there are altogether in the whole of France, 7 faculties of theology, 9 of law, 3 of medicine, 9 of science, and 7 of literature. All these are under the direct control of the government, as represented by the minister of instruction. The colleges of France, which answer to the gymnasia of Germany, are twofold,—*1st*, The royal colleges, which are wholly dependent on the government; and *2d*, The communal colleges, which are supported partly by the government and partly by the municipal corporations and departments; but still are under the entire control of the state.

With regard, thirdly, to primary instruction. This has always been, until recent times, in a lamentably defective state. Freedom of instruction existed; the principle of supply and demand had ample scope for operation; the church, too, as well in the Catholic as in the Protestant portions of the country, had the crying deficiency constantly before its eyes, but comparatively little was done to remedy the evil until the subject was taken up warmly by the government. In the year 1831, under the enlightened *régime* of M. Guizot, M. Cousin was sent on a mission into Holland and Germany, to report on the system of popular education as there organized and carried out. The well-known and elaborate reports which he compiled as the result of this tour of examination, formed the basis for a new law, which was first carried into effect in the year 1833.

This law provides, first of all, for the complete liberty of education; that is, it allows any one, under certain defined conditions, to assume the office of a teacher, and to open a private school. Moreover, it admits of denominational schools being enrolled on the government list of educational institutions, and awards them stipends on the same principle as the rest. The chief object of the law, however, is to provide for the establishment and proper regulation of communal schools throughout the whole country. To give any idea of the principles on which the law is founded, the sources of the pecuniary supplies, and the general mode of superintendence, I subjoin the following excerpts from the text of the law as then brought into operation. After explaining the difference between primary and secondary education, and defining the conditions under which persons are authorized to become public teachers, the law proceeds as follows:—

"*Art. 8.*—The public primary schools are those which are maintained in part or entirely by the communes, the departments, or the state.

"*Art. 9.*—Every commune is bound, either by itself or united to one or more neighbouring communes, to maintain at least one elementary primary school.

National
Education.

"In cases where local circumstances permit it, the minister of public instruction may authorize, after having heard the municipal council, under the title of communal school, schools more particularly belonging to one or other of the religious denominations recognised by the state.

"*Art. 10.*—The communes, chief towns of departments, and those whose population exceeds 6000 souls, must have, in addition, one *superior* primary school.

"*Art. 11.*—Every department is bound to maintain a normal school, either alone or in union with one or several neighbouring departments.

"The general councils will deliberate upon the means of securing the support of the normal schools. They will deliberate also upon the union of several departments for the support of a single normal school. This union must be authorized by royal ordinance.

"*Art. 12.*—There will be provided for every communal teacher—

"1. A conveniently situated residence, equally to serve him as a habitation as to receive pupils.

"2. A fixed salary, which must not be less than 200 francs for a primary elementary school, and 400 francs for a primary superior school.

"*Art. 13.*—In default of endowments, donations, or legacies, which assure a residence and a salary conformable to the preceding article, the municipal council will deliberate on the means of providing for it. In case of any deficiency of the ordinary revenues for the establishment of the primary communal, elementary, and superior schools, they will be provided by means of a special tax, voted by the municipal council; or, in default of the vote of this council, established by royal ordinance. This tax, which must be authorized each year by the financial law, must not exceed three centimes, in addition to the other taxes upon persons or property.

"When communes are not able, either alone or in union with several, to procure a locality and to secure a salary by means of this contribution of three centimes, the recognised necessary expenses of primary instruction shall be provided for, if the funds of the department are insufficient, by an especial tax voted by the council-general of the department; or, in default of the vote of this council, it shall be established by royal order. This tax, which must be authorized each year by the financial law, shall not exceed two centimes.

"If the centimes thus imposed on the communes and departments are not sufficient for the wants of primary instruction, the minister of public instruction must provide for them by means of a supply, which shall be carried over annually for primary instruction to the budget of the state. Each year there shall be annexed to the proposition of the budget a detailed account of the manner in which the funds were employed which were granted for the preceding year.

"*Art. 14.*—In addition to the fixed salary, the communal teacher shall receive a monthly fee, the rate of which shall be regulated by the municipal council, and which shall be collected in the same form, and according to the same rules, as the direct public contributions. This sum shall be drawn month by month, in accordance with a register of the pupils, certified by the teacher, examined by the mayor, and rendered valid by the under-prefect.

"Those pupils of the commune or of the united communes whom the municipal councils have designated as unable to pay any recompense, shall be admitted into the communal elementary school gratuitously.

"*Art. 17.*—There shall be in connection with each communal school a local committee of superintendence, composed of the mayor or his assistant, the president, the rector or minister, and of one or more of the chief inhabitants, nominated by the committee of the district.

"Several schools of the same commune can be united under the management of the same committee. When, in

National
Education.

consequence of the article 9, several communes are united to maintain a school, the committee of the district must nominate, in each commune, one or more of the chief inhabitants to form a part of the committee.

"*Art. 18.*—In every district of the under-prefecture a committee shall be formed, especially charged with the superintendence and encouragement of primary instruction.

"*Art. 19.*—The following are members of the district committees:—

"The mayor of the chief town, or the oldest of the mayors of the chief town of the district. The justice of the peace, or the oldest of the justices of the peace of the district. The priest, or the eldest of the priests of the district. A minister of each of the other creeds recognised by the law, who officiate in the district, and who have been nominated according to the second paragraph of article 17. A head-master, principal of a college, professor, rector, head of an institution, or master of a school, nominated by the minister of public instruction, when there are schools, institutions, or colleges in the district of the committee. A primary instructor, residing in the district of the committee, and nominated by the minister of public instruction. Three members of the council of the district, or of the chief inhabitants, nominated by the said council. The members of the general council of the department, whose real place of residence is in the district of the committee. The prefect by right presides over all the committees of the department, and the under-prefect by right presides over all those of the district; the king's procureur by right is a member of all the committees of the district. The committee chooses its vice-president and secretary every year; the latter may be taken from amongst their own number. When a secretary is appointed who is not a member of the committee, he becomes one by his nomination.

"*Art. 21.*—The communal committee inspects the public and private schools of the commune.

"It watches over the salubrity of the schools and the maintenance of discipline, without any detriment to the prerogative of the mayor in matters of municipal police.

"It finds out if everything has been provided for the gratuitous education of poor children.

"It prepares a list of children who do not receive primary instruction, neither at home nor in any private or public schools.

"It causes the committees of the district to be made acquainted with the different wants of the corporation, with regard to primary instruction.

"*Art. 22.*—The committee of the district inspects, or causes to be inspected by delegates taken from amongst its members or from its own body, all the primary schools in the district. When the delegates have been chosen out of the committee, they have a right to be present at the meetings, and to have a deliberative voice.

"When the committee judges it necessary, it unites several schools of the same commune under the inspection of the same board, as it has been prescribed in article 17.

"Every year it sends to the prefect, and to the minister of public instruction, an account of the condition of all the primary schools of the district.

"It gives its opinion on the assistance and the encouragements to be granted to primary instruction. It urges necessary reforms and improvements.

"It nominates the communal teachers upon the presentation of the municipal council, proceeds to their installation, and receives their oath.

"The communal teachers are to be appointed by the minister of public instruction.

"*Art. 25.*—There shall be in each department one or more commissioners of primary instruction, charged to examine all those who are candidates for certificates of capa-

National
Education.

city, whether for elementary primary instruction, or for superior primary instruction; and they shall deliver the said certificates under the authority of the minister. These commissioners shall also be charged to examine pupils of the normal school at their entrance and on their departure from the institution.

"The members of these commissions shall be nominated by the minister of public instruction.

"The examinations shall take place in public at times appointed by the minister of public instruction."

The law, of which the above are some of the principal provisions, was carried into effect in the year 1833. That it did not remain a dead letter, but was applied with vigour and success, may be seen from the fact, that in ten years from its first establishment, *i.e.*, in the year 1843, the following items appear amongst the statistics published by the Board of Education:—

Number of communes in France	37,038
Number provided with schools	34,578
Number not yet provided	2,460
Total number of primary schools	59,828
Number of inspectors	87
Number of sub-inspectors	113
Evening classes for labourers	6,434
Total number of children attending primary schools	3,164,297
Number admitted gratuitously	763,820
Number of normal schools	78
Number of professors in the same	495
Number of colleges	358
Number of scholars in them	31,316

It could hardly be expected that this vast mass of educational machinery could in ten years be brought into a high state of efficiency; still, there can be no doubt but that a noble effort was made, which, if steadily carried out, in process of time will elevate the peasantry and people of France to the highest rank amongst the educated nations of Europe.

American
education.

Having now gone through the system of national education followed in some of the principal countries of Europe, we pass over to America, where a totally different kind of political life prevails, and where the school system is based upon more popular principles. In most of the United States (in which a very complete institution for popular education exists) we find a system characterized by the extreme minimum of centralization. The last of the theories we before noticed is here almost perfectly realized,—that, namely, in which the government indeed *provides* for education, but does so entirely through the people. The question of education is not even mooted in the central Congress of the States; it is left wholly for the authorities of each state to determine whether they will have any system of education or not, and if so, how it shall be carried on. Some of the states, accordingly, have no public education at all; the greater part, however, have established a system of education by law, though the details of the act appear very different as we pass from one state to another.

United
States.

We turn first to the state of Massachusetts, the original core and centre of the American people. The practice of having schools legally maintained according to the wants of the population is one which, in New England, came down from the time of the first Puritan settlers. As the population advanced, however, as immigration increased from year to year, and the country became involved in various political struggles, popular education fell into the background, so that it became totally insufficient in quantity for the wants of the people. It is only within the last twenty or thirty years, indeed, that any large and well-directed efforts have been made for its improvement; but these efforts have certainly been upon a scale which cannot but excite admiration and approval.

Every township in the state, comprising 150 families, is

bound to maintain two schools during nine months of the year, or three schools during six months. If it contain 500 families it must maintain two schools throughout the year, or three schools during eight months. In these schools reading, spelling, writing, arithmetic, English grammar, and geography, must be taught.

National
Education.

Every township containing 500 families must also maintain a superior kind of school, called an English high-school, in which geometry, algebra, surveying, and history are taught, besides the other usual branches. Townships containing 4000 souls must maintain, in addition, a classical high school; and the whole of these schools must be open to the entire population, within the given age, without any distinction whatever. Each township can divide itself into districts for the better carrying out of the government of the schools. Should any township neglect to provide school accommodation at this rate, it is liable to pay a fine of double the average cost of the schools themselves, out of which the proper schools are provided by the state. Any child unlawfully excluded from such schools may, through the parent or guardian, prefer a claim before the legal tribunals for compensation.

So far the provision of the government extends, but no farther. All the other details are entirely in the hands of the township itself, which holds a yearly meeting for voting in supplies and appointing officers, to whom the management of the school affairs are to be entrusted. Every male inhabitant, twenty-one years of age, is empowered to vote at this meeting. There are two committees usually appointed,—one to manage the business affairs, the other to overlook and inspect the schools. These committees are bound to perform their duties punctually and efficiently, and receive a pecuniary compensation from the township for every day they are employed in the school business.

Of late years some important additions have been made to this system. It was agreed that the monies procured by the sale of the state lands should be consolidated into a permanent fund for the benefit of the education of the people. A board of education was instituted also in 1837, which was not intended, indeed, to exercise any *authority* over the townships, but to recommend improvements, and to distribute the money from the fund equally through all the townships. A normal school was also founded at the public expense. This small attempt at centralization has been productive of much benefit. To it we owe the labours of Horace Mann and others in the cause of public education, as well as many of the more important improvements which have gradually sprung up.

To give some idea of the kind of differences which exist in the school laws of the several states, I quote the following passage from a little work entitled *A Digest of the Common-School System of the State of New York*, by Mr Randall, the general deputy-superintendent, in which the principal points of the school laws in *that state* are succinctly laid down:—

"The affairs of each district are managed, under the general direction of the inhabitants entitled to vote therein, by three trustees (one of whom is annually elected, and who hold their offices for three years), a district clerk, collector, and librarian. These trustees are required annually, between the 1st and 15th of January, to report to the town-superintendent the length of time a school has been taught in their district during the preceding year by qualified teachers, the amount of public money received and expended, the number of children taught, the number between five and sixteen residing in the district, together with such other information as may from time to time be required of them by the superintendent of common schools. They have power also, and are required, to call annual and special meetings of the inhabitants to make out tax-lists of all taxes voted for district purposes, and annex their war-

National
Education.

rant for the collection of the same; to purchase on lease sites for the school-house, when designated by the inhabitants, and to build, hire, or purchase, keep in repair, and furnish such school-house, with necessary fuel and appendages, out of the funds collected and paid to them for that purpose; they have the custody and safe keeping of the district school-house, contract with and employ teachers, and make out the necessary rate-bill for so much of their wages as is not paid from the public funds applicable to that purpose, exempting indigent persons either wholly or in part, and levying such exemption upon the taxable property of the district. The town superintendent is annually elected by the people at town meetings, and has the general supervision of the interests of common schools in his town; visits and inspects each school within his jurisdiction as often at least as once in each quarter; advises and directs as to the government, discipline, and course of instruction therein; examines and licenses teachers annually; receives and apportions the school-money belonging to his town among the several districts, according to the number of children between the ages of five and sixteen residing in each at the date of its annual report; forms, regulates, and alters school districts, in conjunction (when required by the trustees of any district interested) with the supervisor and town-clerk; prosecutes for and collects all fines and penalties imposed by the school act upon the officers of districts; and annually reports to the county superintendent the number of districts in his town, the amount of public money received and expended, from what sources received and how expended, together with a condensed abstract of all the reports of the trustees of districts made to him, and a variety of other information relative to the condition of the several schools under his charge. The county superintendent is appointed once in two years by the board of supervisors, and is removable by them, and by the state superintendent, for neglect of duty or mal-conduct. He is charged with the general supervision of the schools of the country; hears and determines all appeals arising within his jurisdiction, subject to the review of the state superintendent; examines and grants permanent certificates of qualification to teachers, which are available throughout the country; may, with the concurrence of any town superintendent, annul any certificate granted by the latter; annually visits and inspects the several schools of the county as often as practicable; inquires into all matters relating to their government, course of instruction, the condition of the school-houses, and of the districts generally; advises and counsels with the trustees and other officers in relation to their duties, and with the several teachers in relation to their modes of teaching, government, and discipline, course of studies, text-books, &c.; and generally, subject to such rules and regulations as the state superintendent may from time to time prescribe, is directed 'by all the means in his power to promote sound education, elevate the character and qualifications of teachers, improve the means of instruction, and advance the interest of the schools committed to his charge.' He is required annually to report to the state superintendent the result of his examinations and inspections, together with a great variety of useful statistical information relating to the condition of the several schools under his charge; an abstract of all the reports of the town superintendents; and such other suggestions for the advancement and improvement of the interests of education generally as he may deem advisable. These officers call periodical meetings of the town superintendents, teachers of common schools, officers and inhabitants of districts, for the purpose of mutual consultation and advancement; organize teachers' institutes preparatory to the summer and winter terms, with the view of instructing the several teachers and preparing them for the efficient discharge of the duties devolving upon them, and deliver familiar lec-

tures in each district at each visitation. The ability, fidelity, and success with which their duties have thus far been discharged have exerted a highly beneficial influence on the interests of education."

National
Education.

In Canada we have a country lying, politically speaking, midway between England and the United States, being loyally devoted to the British crown on the one side, but partaking largely of the spirit of American institutions on the other. In Canada, accordingly, a system of national education has been adopted and legalized similar in its main features to that of the state of New York, but containing some peculiar details of its own. Here, as in several of the states of America, the religious question has presented some difficulties; but it has in each case been solved virtually in the same way, namely, by showing that the school is, properly speaking, a national institution,—that it must hold an equally impartial position towards all classes of the community who support it; and that, in consequence, only those elements of Christianity which are common to all can be introduced into the plan of public instruction. I cannot give a better view of the grounds on which this point is argued than by quoting the words of Dr Ryerson, the chief superintendent of the Canadian schools. "To require the teacher," he says, "in any common day-school to teach the catechism of any religious persuasion, is not only a work of supererogation, but a direct interference with the disciplinary order of each religious persuasion; and instead of providing by law for the extension of religious instruction, and the promotion of Christian morality, it is providing by law for the neglect of pastoral and parental duty, by transferring to the common-school teacher the duties which their church enjoins upon them, and thus sanctioning immoralities in pastors and parents, which must in a high degree be injurious to the interests of public morals, no less than to the interests of children and of the common schools. The demand to make the teacher do the canonical work of the clergyman is as impolitic as it is selfish. Economy, as well as patriotism, requires that the schools established for all should be open to all upon equal terms, and upon principles common to all, leaving to each religious persuasion the performance of its own recognised and appropriate duties in the teaching of its own catechism to its own children. Surely it is not the province of government to usurp the functions of the religious persuasions of the country; but it should recognise their existence, and therefore not provide for denominational teaching to the pupils in the day-schools, any more than it should provide such pupils with daily food and raiment, or weekly preaching, or places of worship. As the state recognises the existence of parents, and the performance of parental duties, by not providing children with what should be provided by their parents, namely, clothing and food, so should it recognise the existence of the religious persuasions, and the performance of their duties, by not providing for the teaching in the schools of that which each religious persuasion declares should be taught by its own ministers and the parents of its children. But it may be asked, Ought not religious instruction to be given in day-schools, and ought not government to require this in every school? I answer, what may or ought to be done in regard to religious instruction, and what the *government ought to require*, are two different things. Who doubts that public worship should be attended and family duties performed? But does it therefore follow that government is to compel attendance upon the one or the performance of the other? If our government were a despotism, and if there were no law or no liberty, civil or religious, but the absolute will of the sovereign, then government would of course compel such religious and other instruction as it pleased, as is the case under despotisms in Europe. But as our government is a constitutional and a popular government, it is to com-

National
Education.

pel no farther in matters of religious instruction than it is itself the expression of the mind of the country, and than it is authorized by law to do. Therefore, in the *General Regulations on the Constitution and Government of Schools respecting Religious Instruction*, it is made the duty of every teacher to inculcate those principles and duties of piety and virtue which form the basis of morality and order in a state; while parents and school teachers, or school managers, are left to provide for and give such further religious instruction as they shall desire and deem expedient."

By this it will be seen that in Canada the state does not ignore religious instruction, nay, rather sanctions it; but it says,—“Religion in the denominational sense is not our province. So far as we are concerned with the schools, we can only recognise what is common to all; and whatever religious instruction is demanded over and above this must be left either to the supplementary education of the family and the church, or must be a personal arrangement between the school managers and the parents of the scholars.”

The system of secondary education in Canada is not as yet so far developed as in some of the United States, but the question is in progress, and will no doubt end in the establishment of grammar schools for a higher and classical culture in all the larger towns or parishes. With regard to *university education*, this, both in Canada and the States, rests at present mainly upon private foundations.

Education
in the
British
Isles.

It is time, now, that we come to our own country, which, so far as England at least is concerned, has proved the most backward of any of the more progressive nations in adopting any system of national education. Those who can look back upon the state of education in England some twenty or thirty years ago, can well remember what a blank this whole department of our national life presented. The educational zeal, indeed, which the Reformation called into play provided an extraordinary number of charities and bequests to be appropriated to this purpose. Some of these were devoted to those usually very useless institutions called grammar schools, and some others more directly to clothe and teach a limited number of poor children in the parish. It is believed, indeed, that if the whole of the property accruing from such charities were consolidated and properly applied, it would prove a most important element in carrying forward the entire education of the country. In spite of all this, however, the mass of the people remained in gross ignorance down to the early part of the present century.

Lancasterian
schools.

About the year 1808 Joseph Lancaster, a member of the Society of Friends, began his labours in London on the site now occupied by the British and Foreign School Society, and not only gathered a vast number of children around him, but imbued a number of young men and women with his principles and methods, who were sent out into various parts of the country to carry on the same work there. This was the germ of the present normal school in the Borough Road, Southwark.

Bell's
schools.

Lancaster, as a teacher, admitted no catechism or form of denominational doctrine into the schools, but gave daily religious instruction from the Bible, avoiding all points of difference or dispute. Nearly at the same time Andrew Bell, who had been previously engaged in the instruction of the Orphan School at Madras, returned to England, and was employed to use his experience in organizing schools very similar to those of Joseph Lancaster, in connection with the National Society of the Church of England. The starting-point of popular education in England, therefore, was the institution of the British and Foreign, and of the National School societies, under whose patronage a number of so-called British and National schools were gradually spread throughout the country. It need not be added, that the quantity of education thus provided could bear no sort of relation to the actual wants of the country. Neither was the quality of the instruction for a time much better.

The funds of the schools were usually small,—the teachers ill educated. No normal schools, in the proper sense of the word, existed, and the monitorial or mutual system of instruction alone prevailed.

National
Education

This state of things went on till about the year 1833, Privy when the lords of the Privy Council, seeing the great destitution of the country, began to give small grants from the Treasury in aid of school buildings, through the British and Foreign and the National School Societies respectively. In 1839, when the demands for such grants began to increase, a Committee of Council on Education was formed in order the better to regulate and extend them. Aid was also afforded to normal schools; and the resolution was passed, that every government grant should henceforth carry with it the right of government inspection. With reference to the inspectors, however, the archbishops were to have the right of veto upon their appointment on behalf of the National schools, and the British and Foreign School Committee to have the same right on behalf of the British schools. This state of things continued till the year 1846, when Sir James Shuttleworth, who had been acting from the first as the secretary of the Education Committee, brought forward a series of minutes for apprenticing pupil teachers in schools; for granting augmentation to teachers' stipends, on their submitting to an examination and receiving a certificate of competency; and for making grants of books, maps, and apparatus.

These minutes of 1846 were only the commencement of a series of developments which have been going on to the present time. The grants have since then been thrown open virtually to *all religious denominations*, and indeed to all private individuals or commercial companies who choose to take the initiative in providing education for the people; the only stipulation in regard to religious teaching being, that some portion of the authorized version of the Scriptures be daily read in all the Protestant schools receiving grants.

To give some idea of the *extent* to which popular education, as aided by the state, has now been developed, the following statistical facts, taken from the minutes of the Committee of Council on Education for 1856–57, will be sufficient, without going into minor details. It should be observed, however, that the grants to schools in Scotland are here included:—

1. *Money expended by Government in England and Scotland for Educational purposes between December 31, 1855, and December 31, 1856.*

In building and enlarging elementary schools	L.74,470	11	1
Do. normal schools	9,586	18	11
In providing books and maps	3,199	5	7
Do. scientific apparatus	757	10	11
In aiding the salaries of certificated teachers.....	52,088	6	10
In stipends to assistant teachers.....	5,050	3	6
In stipends to pupil teachers	158,228	16	2
In capitation grants	20,079	15	0
In grants to training schools	45,785	6	8
Reformatory and industrial schools	8,158	15	10
Pensions to teachers.....	393	13	0
Inspection	30,829	15	10
Expenses of administration in London	15,004	3	1

Total..... L.423,633 2 4

2. *The above amount has been divided amongst the different classes of schools as follows:—*

Church of England schools	L.268,230	2	1
British and foreign schools	39,474	4	7
Wesleyan schools	22,789	16	1
Roman Catholic schools.....	19,185	1	0
Parochial Union schools.....	5,509	11	8
Church of Scotland schools	28,534	14	8
Free Church schools	23,520	3	11
Episcopal Church schools	3,308	9	4
Administration	13,080	19	0

Total..... L.423,633 2 4

National
Education.

3. Miscellaneous Facts.

Number of certificated teachers paid by government	4,373
Number of assistant teachers paid by government.....	225
Number of pupil teachers	10,245
Number of training schools aided by government.....	32
Number of schools under inspection.....	7,454
Number of children provided for in the same.....	877,762
Number of masters and mistresses annually supplied by the training schools, about	1,300

It would give a totally false estimate of popular education in England and Scotland to regard this as being any kind of approximation to its whole extent. The government grants are merely *offered* to those who wish to accept them, under condition of being inspected and reported on. A large number of schools of all denominations still exist, which have made no application for government aid; some because they disagree altogether with the *principle* of state interference, some because the teachers are unwilling to submit to inspection or examination, and some because the managers are not prepared to fulfil the pecuniary or other conditions on which the grants are awarded. Added to this there is yet a vast number of schools of private adventure, each of which manages to gather together sufficient scholars to yield some kind of maintenance to the teachers. All this put together furnishes a tolerable idea of the nature and amount of primary instruction in the elementary schools of the country. A large portion of the smaller towns and country parishes are now well supplied with the means of instruction, and great efforts have been made to meet the wants of the large and populous towns also; but still, if we are to judge by what presents itself to the eye of an attentive observer, as also by the statistics of the population of the country, placed side by side with those of the primary school, we must come to the conclusion that a very great deficiency of school accommodation yet exists. This conclusion is fully borne out by the education returns of the last census. The total number of scholars returned by the registrar-general as being an average attendance in *all kinds of schools* in March 1851, was 1,754,814, which is only a centesimal proportion of 43·8 of the whole population of England and Wales between the ages of five and fifteen. When we consider, moreover, that the children of the middle and upper classes are nearly all included in this aggregate, and that of the rest a large number of children are only in dame schools, or other similar schools of private adventure, where the instruction is hardly worth the name, the result must appear anything but flattering in regard to the amount and character of the education gained by the children of the labouring classes in primary schools.

English,
European,
and American
educational
agencies
compared.

Let us next compare the agencies by which the elementary education of this country is administered with those which we have already noticed in Europe and America. In the other countries of Europe the initiative and the direction of all popular education lie with the governments. The people, indeed, are called upon to find the funds requisite for supporting the schools, but they have nothing to do with what is taught, nor with the manner of teaching; and very little with the appointment of the teachers or the superintendence of the schools. It is true that liberty of teaching exists under certain conditions, and that there are institutions scattered here and there which have sprung up from private adventure or from religious benevolence; but the great mass of the schools are *governmental*. In England, on the contrary (if we except the pauper schools, and those belonging to naval, military, and penal establishments), no schools whatever are *initiated* by the government, neither does it reserve for itself any voice whatever in the management of them. It simply comes to the aid of private efforts, and proffers grants, on certain conditions.

If we turn to America, another and a wholly different principle prevails. Here the government *does* take the

initiative. It says there *must* be schools of such and such a character in proportion to a given population, and holds itself responsible for seeing that this obligation is carried out. Here, however, the governmental functions end. It is the people, in their capacity as free citizens, who determine all the rest,—the nature of the buildings, the salary of the teacher, the methods of instruction, the plan of supervision, the amount of school fees, and the whole apparatus of instruction.

The English method stands alike apart from both the continental and American schemes. Perhaps the best idea we can give of the system is this,—That the religious denominations undertake to educate the people, but that the government comes to the aid of all alike, so far as they choose to avail themselves of its assistance.

There are some advantages, perhaps, attached to the English system of popular education which could hardly exist in the other cases. The most obvious of these is the amount of local interest which they gather round them. A governmental or municipal institution is ordinarily put under some kind of official management, and is carried forward by the power of authority only. Such authority is no doubt highly useful, and tends to keep the institutions to which it applies in excellent working order. We must remember, however, that in the case of the more ignorant classes something different from a school worked by authority is desirable. The children, and their parents as well, need humanizing and softening. They want to come into contact with those above them in the social scale, and regard them in the light of men desirous to take a personal interest in their welfare. The real value of the voluntary principle, accordingly, lies in the healthy impulses, the daily encouragements, and the moral aids that are afforded both to the teacher and scholar by the presence and personal interest of those who occupy stations of influence in the several localities where the schools are situated. However possible it might be to have schools formally as complete, and education quite as widely extended, by the instrumentality of paid officials only, yet no such instrumentality could wholly supply the loss of that daily personal influence which is exerted so largely on the present system by those who seek to further the education of the poorer classes around them, simply and solely with a desire to promote their welfare. This is certainly an element in our present national education which may be well guarded with some degree of jealousy, and which must not be lightly swept away by the rising tide of any universal national system.

Advantages of
the English
system.

When we have said this, however, we have said *nearly all* that can be urged in favour of the present system. Its disadvantages are obvious at first sight:—1st, As a system of primary education it entirely fails in completeness. The supply of school accommodation through the country is entirely left to chance. If persons *happen* to be interested in a given locality they may originate schools in it; but there is no guarantee for any such schools being set on foot. Accordingly, some districts have more school accommodation than is at all necessary; while others, perhaps more populous ones, are entirely destitute. Nay, the more poor and needy a locality is, the less likely is it to be supplied, because there are fewer residents of a class who are able and willing to do anything to supply the want. This is not a mere theoretical objection based on the natural tendencies of the plan, but a fact of actual experience. In most of our large and populous towns we find ample school accommodation in the *more favoured localities*, but a vast destitution in the densely-populated districts, where it is most of all required. 2d, The plan has nothing national about it. The English people, as such, have nothing to do with schools,—nothing to do, therefore, with their own education. They are left to the all-absorbing interests of commerce, and never called upon to take part in any great plans of popular

Disadvantages of
the English
system.

National
Education

reformation and improvement. If individuals or religious congregations choose to busy themselves about these matters they can,—and fortunately for the country many do; but the few are really undertaking the work of the many; that which ought to be a matter of national importance, in the burden of which every one ought to take his share—I mean the education of the whole community—is left to the comparatively feeble efforts of a small philanthropic minority, little able to cope with the magnitude of the question, though aided liberally from the public purse. 3d, The plan is by far too sectarian in its whole character. Had the government taken a perfectly uniform attitude towards all classes of schools; had it simply agreed to aid the secular and moral education in which the whole country is equally interested, appointed inspectors to report on *all schools alike*, and left the religious element to each party to supply for themselves, as in Canada, there would have been at least *one central point of unity* around which the whole education of the country might eventually have gathered, so as to form some approach to nationality; but in place of this, sectarian trust-deeds, *even more stringent than they were before*, have been sanctioned; the system of sectarian inspectors has been admitted; the religious element has been included in the government reports in the case of the national schools, thus severing them in their relation to government from the rest; and the denominational system has accordingly been rendered *complete*. In this way, the government aid and inspection, which might have gradually softened down the sectarian spirit and formed a rallying-point of national unity, has really legalized it and made it permanent; and schools are now seen rising up in rivalry one over against the other, both of which are equally paid for from the national funds. 4th, The present plan is not to be recommended on the score of economy. Were the country divided into districts, and the educational wants of each district taken into account and properly supplied, the school question would assume an *economic* form. At present the partial distribution of school accommodation, assuming as it does a *denominational* form, goes directly contrary to all principles of economy. Large sums are spent in districts where schools are not all required. One denomination planting a school in a given locality excites the envy and jealousy of another; and straightway a rival establishment must appear, both of which languish for want of scholars, and perhaps of funds also, just because the neighbourhood is only sufficient to support one good school. Double the school accommodation that is requisite will have to be supplied on the present principles before the wants of the whole country are met.

The same want of economy exists in all the details of the government administration. Instead of the inspectors being purely governmental officers, which they were first intended to be; instead of each having a limited district within which he reports upon all classes of schools; there are no less than seven different classes of inspectors roaming the country, and crossing each other's orbits in every direction, in order to suit some particular denominational type of schools. Thus there are National school inspectors, British school inspectors, poor-law inspectors, Church of Scotland inspectors, Free Church inspectors, and an Episcopal Church of Scotland inspector. All the official documents and books at the office of administration, moreover, have to be kept separately, for each of these different classes of schools, so that the whole work is complicated in every possible way.

The consequence of possessing a system of education so partial in its extent, and incomplete in its scheme of operation, is that a great number of spontaneous institutions have sprung up to supply the deficiency. The number of dame schools, and schools of private adventure held by wholly incompetent persons, is still *incredibly great* in all the more populous towns of the country.

National
Education

Again, with regard to middle education, this is thrown almost entirely upon the principle of supply and demand. The grammar-school charities which exist throughout the country are so inconsiderable, as compared to the whole of the middle classes, and those which do exist are for the most part so imperfectly administered, that they can hardly be taken into account as any valid element in the higher education of the country. Nearly the whole of the middle classes in England are virtually shut up to the principle of *boarding-schools*, in which we find of course every possible variety both of matter and of method. A few well-endowed grammarschools, and a few other proprietary day schools, form the only exceptions to this general statement. This may certainly add somewhat to the individuality of the English people; but as a system of national education for the middle classes it is, as a whole, the least efficient and the most expensive of any that could possibly be devised. A good rating system like that of America, which should supply higher as well as primary schools in every district throughout the country, would be an enormous saving to the whole of the middle classes of the community, and give them as well a guarantee of efficiency such as they cannot now possibly possess.

Another and very important mode in which private effort has sought spontaneously to supply the deficiency of popular education, is by putting the means of improvement into the hands of the *adult population*. I refer now to the rise of mechanics' institutes, mutual improvement societies, and other institutions of a similar nature.

The rise of these institutes and societies may be traced to the efforts of Dr Birkbeck in Glasgow, in the year 1800, to form a class of mechanics in connection with the Andersonian Institution, to whom he proposed giving instruction in the rudiments of natural and mechanical philosophy. Their further development, however, amongst the larger towns of the country generally dates no earlier than about the year 1823. Their primary intention was to impart instruction to working men in the rules and principles of the various arts with which they were already practically acquainted. Hence, for a considerable time after their first rise the prevailing tone and tendency of their operation was *scientific*. Lectures were given on the elements of natural philosophy, on chemistry, on mechanics, on geometric drawing, and on a variety of other topics bearing more directly upon the occupations of the artisans. In addition to this, libraries were collected, and the books lent out to the members at a very low rate; evening classes were also formed in some places for regular *courses* of instruction in the various arts and sciences.

In the course of some years, however, the general features of these institutions began to change. Scientific lectures lost their novelty; the expenses attendant upon the regular engagement of scientific men were found to be too great a drain upon the institutions; a large number of the subscribers preferred to hear something more light and amusing; and thus the scientific element began to make way for music, poetry, and light literature.

The following table gives a fair idea of the process of this change, as seen in the Mechanics' Institution at Manchester:—

Number of Lectures on	1835 to 1839.	1840 to 1844.	1845 to 1849.
Science.....	295	127	88
Mental Philosophy.....	8	16	2
Literature and Education...	53	80	84
Fine Arts and Drama.....	99	55	55
Total.....	395	278	229

If a similar list were continued down to the present time, the same two results would be still visible,—namely, first

National Education. a gradual falling off of the aggregate number of lectures given; and secondly, a pretty steady tendency toward light and literary subjects, in place of philosophy and science.

At the same time, it is but just to say that many *improvements* have been introduced. Day and evening classes for boys and girls, as well as adults, have in many instances been added to the ordinary programme; and in some instances, as in Liverpool, a flourishing middle school of a very superior character has been gradually developed.

The statistics of mechanics' institutes for the United Kingdom, in the year 1853, were as follows:—

	Number of Institutes.	Members.	Vols.	Issues of Books, 1850.	Number of persons attending Evening Classes.	Number of Lectures delivered in 1850.
England.....	610	102,050	691,500	1,820,748	16,020	5,084
Wales.....	12	1,472	6,855	16,900	280	115
Scotland.....	55	12,554	59,681	154,747	1,638	431
Ireland.....	25	4,005	57,500	33,800	182	310
Total.....	702	120,081	815,516	2,026,095	18,120	5,940

This table shows that there is at least a very large amount of machinery at work, which if not *all* of the most improving character, yet cannot fail, as a whole, to exert a very considerable influence upon the population of our large towns. The great drawback to their further efficiency lies in the want of early school training amongst the working classes. This want renders it extremely difficult to interest them in useful objects of study, and tends, consequently, to divert the very purposes of the institutions raised for their benefit, from what is solid and useful, to subjects which are harmlessly amusing. We may hope, however, that this is only a passing phase of the question. Education is now advancing amongst the juvenile population; a large amount of mind is being called out by the improvements made in the primary schools; and this will, ere long, produce a corresponding call for mental food amongst adults.

In addition to this, the union now formed amongst mechanics' institutes in the different counties is tending greatly to their improvement and their more complete organization, and it appears likely that they may yet, ere long, become a more powerful engine than ever in the education of the people. Indeed, there are already symptoms of the co-operation of the government with popular institutions of this character, which, if properly carried out, cannot fail to give them a still wider range and more abiding influence.

In the view which has been given of the state of public education in England, it is not intended to include the case either of Scotland or Ireland; in both which countries peculiar institutions exist that greatly modify the whole complexion of the subject.

Scottish education.

Scotland started on the pathway of education from the very time of the Reformation. The early Reformers, in adopting the parochial divisions of the country, did not apply them simply to an *ecclesiastical*, but also to an *educational* purpose. In every parish they procured the establishment of a school as well as a church, with the right of presbyterial inspection, and endowed it with landed property. These schools were the centres of much unobtrusive educational activity throughout those long years of the seventeenth and eighteenth centuries, when England and Ireland were almost in a state of *Egyptian darkness* in regard to the education of the masses of the people. The parish schools of Scotland having originated at a time when Latin was the almost universal medium of mental culture, have always retained more or less of a higher and classical element; and by so doing have nurtured the taste for a middle-class day-school education to a much larger extent than what has ever existed in England. The preference of the *day* to the *boarding* school, indeed, is one of the

VOL. XV.

educational features in which Scotland differs most obviously from England in relation to the training of the middle classes.

National Education.

As the population of Scotland increased, it was found that the original parochial endowments proved wholly insufficient to meet the growing wants of the people. This has led to a series of voluntary efforts, for the most part denominational, intended either to supplement the deficiency, or to give its proper weight to each sect in the educational concerns of the country. So early as the year 1701 the Society for Promoting Christian Knowledge was formed with the especial design of supplying the wants of districts where the parochial education was not sufficient.

Early in the present century the Inverness Society for the Education of the Poor, and the Ladies' Gaelic School Association, were formed chiefly to aid the cause of education in the Northern and Western Highlands. About the year 1812 the Sessional School was formed in Edinburgh, which gave a great impetus to education in the right direction, by the adoption of more modern and approved plans. In 1824 the General Assembly education scheme was carried into execution, which has now 180 schools under its jurisdiction; and in 1843 the disruption of the Church of Scotland led to a new series of efforts on the part of the seceding body, which has ended in the establishment of between seven and eight hundred schools throughout the country. All these different bodies have now availed themselves of the aid held out by the Committee of Council on Education; so that the denominational principle has now come into play precisely in the same manner as we have shown it in regard to England, and has attempted to supply its own deficiency by means of the government grants now held out for acceptance.

The net result of all these efforts is, that Scotland is now supplied with schools, numerically considered, perhaps equivalent, or nearly so, to the wants of the whole population. "What is now required," says one of the government inspectors in the report of 1856, "seems to be not so much any great accession to the *number* of the schools, as a more real, vital, availing character in the instruction which many of the existing schools afford." This does not at all imply that the defect pointed out attaches to the Scottish primary education generally; for it is in fact quite the reverse; but that a considerable number of the schools are languishing from insufficient funds, which tends to paralyze the efforts of the teacher and render the whole school dull and ineffective.

We must refer, lastly, to Ireland, which contains many peculiar features of its own. Grants of public money began to be voted for Irish education from the commencement of the last century, but they were given almost exclusively for the benefit of the Protestant population. The great mass of the people, who consisted of Roman Catholics, remained wholly uneducated. A number of schools thus sprung up through the country, patronized chiefly by different societies and aided by the state. Amongst these were the Protestant charter schools, the Protestant English schools, schools of the Society for Discountenancing Vice, and the schools of the Kildare Society. In 1806 a crown commission was appointed to inquire into the state of schools on public or charitable foundations in Ireland. In 1824 another commission was appointed, whose object was "to discover a mode in which the combined education of Protestants and Catholics might be carried on, resting on religious instruction, but free from the suspicion of proselytism." These efforts ended by the appointment in 1831 of a board of commissioners for national education, whose efforts during the last twenty years in introducing popular education into Ireland have been crowned with the most marked success.

The Irish school plan comes far nearer to the idea of a real *system* of national education than what we have shown

5 M

National Education. to exist either in England or Scotland. It is true there is no educational division of the country, no legal obligation to erect a school in every parish, no public tax for school purposes; but a plan of operation has been laid down which compels the schools aided by government to be open to all, without distinction of religious creed, and which confines the religious instruction to specific periods, in which the children can receive it from their own pastors or teachers.

Under the liberal patronage of government primary schools have been now largely extended, model and normal schools erected, evening schools, industrial schools, agricultural schools, set on foot, and a general stimulus given to social improvement. A vigorous system of inspection is also kept up by the government commissioners. In addition to three head inspectors there are no less than thirty-four district inspectors, who visit each school at least three times every year, and report its progress or deficiencies to the central office in Dublin.

The following statistical details are taken from the reports of the commissioners for the year 1855:—

Number of schools under inspection	5124
Number of children in attendance	538,246
Number of teachers in training	288
Number of workhouse schools	139
Number of model-farm schools	37
Total expenditure by government during the year, L.212,017, 4s. 9d.	

Hints for the improvement of British education.

We have now shown, in regard to our own country, who are the educators, what are the principal agencies employed, and to what extent those agencies are operative. The whole subject presents certainly a very heterogeneous aspect. While on the continent of Europe and in America we have systems of primary education, which carry instruction by force of law into every village and every district; while we see this system of primary instruction still further supplemented by high schools adapted to the commercial and middle classes generally, and these, again, crowned by universities, accessible to all at a very moderate rate of expenditure, England presents nothing whatever of the same kind. We have denominational schools, adventure schools, schools supported by individuals and by commercial companies, schools aided by government and schools not aided, endowed schools, subscription schools, with duplicate variations of every class, in Scotland and Ireland. Similar diversities are also to be seen in the *character* as well as the constitution of the schools. Some are excellent, some miserably bad; some teach religion and theology to the utmost extent, some limit it to a verse or two from the Bible, and some are wholly secular. In relation to *method*, some are monitorial, some collective, some sectional, and some have no system whatever; while, in relation to *locality*, some places are overdone with school accommodation, and others have no accommodation at all. The question therefore comes, Whether it is possible to adjust these facts so as to bring out of them a theory and a practice of education that shall be sound in itself, and suited to the wants of the country at large?

This question no doubt presents many difficulties; neither is it possible to say how many unforeseen obstacles may arise before any plan, however simple and apparently unobjectionable, could be realized. First of all, it is not possible in a country like this to begin virtually *de novo*, as in France and Prussia. The ground is already to a large extent occupied. Charities exist all over the country which have been left expressly for educational purposes. The state church has begun to work the parochial division of the country into an educational as well as an ecclesiastical system, and claims the schools thus originated as an appendage to the church, with which the nation, as such, has no right to interfere. Denominational schools have been planted all over the country in common with almost every sect, who are equally jealous of any foreign interposition.

National Education. The Committee of Council on Education have recognised all these classes of schools, have aided all alike, and have pledged themselves to a certain extent to the denominational system. The stimulus given by the government system of aid and inspection has been, it is true, almost incalculable; and the improvement in elementary schools within the last ten years *unprecedented*. And yet, with all this, the step which the government has taken, when viewed in relation to a future complete system of national education, has been obviously *a step in the wrong direction*. No truly national system can by any possibility grow out of the present minutes of council, unless they are greatly modified in their whole structure and tendency. This is virtually acknowledged by all practical men; and the very attempts which have been made in the House of Commons within the two or three last sessions of Parliament to introduce an education bill, show that some totally new principle must be introduced before any broad or satisfactory system for the country can be realized. In what way, then, can these improvements be introduced so as to co-operate with the agencies already in existence? This is the great practical question of the present moment in regard to national education. To build up any complete theory would be visionary. We shall merely give a few hints to show the direction which we conceive the development of education must take in order to have any chance of present success.

1. First of all, the country should be divided into educational districts. The present parochial divisions of the country are on many grounds objectionable. Not only are they extremely unequal in population and extent, but it is extremely difficult to dispossess the present functionaries, both ecclesiastical and municipal, of the idea that they have some especial claim to precedence in any matters which assume a parochial character. Such claims applied to education would at once prove fatal to any really national system, as it would set the different parties now engaged in it in direct opposition to each other.

2. Having divided the country into districts, the next thing would be to find out, not by *local* but by *governmental* authorities, what is the educational supply, and what are the educational wants of each. To determine this, note must be taken of all the existing schools, of whatever denomination, distinguishing those which are already under the inspection of the Committee of Council from those which are not. Care should be especially taken to look into the amount and the application of all charitable trusts for education, and to report definitely upon them.

3. A third step of great importance would be, to pass an act of Parliament empowering a board of charitable trust commissioners to take these trusts for a time into their own hands, to find out what they will realize by proper management, and to appropriate the amount (according to the spirit, if not to the letter, of the founder's will) to the general education of the district in which the property is situated.

4. The next point would be for a school-rate to be levied on actual property in each district, according to its requirements. This school-rate might take the place of the grants now made to teachers, pupil-teachers, and managers, from the Committee of Council on Education, as well as the voluntary contributions of managers, and would also be employed to plant new schools in the district, wherever the present provisions arising from existing schools and charitable endowments were found to be insufficient.

5. The rate-payers in each district would elect a committee of management totally distinct from any existing parochial authorities, into whose hands the rate funds would be paid, and who would be responsible for its partition to every school, fulfilling certain conditions, according to the number of children in average attendance. They would also carry out the provisions of this act in regard to new schools to be erected in destitute localities.

National
Education.

6. All schools applying for the rate should be examined and reported on by inspectors appointed by government, who should have power to determine whether a school was deserving of support from public funds or not.

7. The *local management* of *existing* schools should not be interfered with; only provision should be made that the religious instruction should be given at a specified time (as in the Irish schools), that parents should have the power to withdraw the child from any kind of religious teaching to which they object, and that the day-school should involve no conditions in regard to attendance at any particular place of worship on the Sunday.

8. The government should not interfere with the religious element of the schools beyond the above stipulations, and demand no reports on it, but should leave it in each case to the local managers to provide for as they think best.

This is of course only a rough sketch of the direction in which education might move forward. All the existing machinery on this plan would remain untouched; all the provisions of the Committee of Council on Education respecting normal schools, examinations for certificates of merit, pupil-teachers, inspection, &c., could be still carried out as before; the only new elements would be the education districts, the principle of a rate, and a school committee in each district,—not to manage the institutions, but to apportion the funds according to the details of the measure. All schools, of course, as far as the government is concerned, would lose their denominational character, and be inspected and reported on by one general class of inspectors, simply as *elementary schools*. In this way, without doing any great violence to the present organized state of things in the country, a system of national education might be gradually consolidated which would combine the advantages of local management and local support with the numerous benefits derived from governmental inspection. Already strong indications have been given that we may look for a union of all political parties in some measure of this kind. For the system of government aid has now gone so far, that it can neither recede nor fully develop itself without certain organic changes.

To make the plan above sketched out *complete*, of course it must comprehend the establishment of middle or high schools, as well as schools for the working-classes. This might at first sight *seem* to involve an outlay which would press too heavily to be endured upon the rate-payers of each district. But, in point of fact, the mere circumstance of comprehending a plan of *middle-class* schools in the general system of national education would be an actual relief to the great majority of the persons upon whom the rate must fall. The middle classes in this country are *now* educating their children in boarding-schools at a very great expense, and are usually getting a very inferior article for their money. By paying a moderate rate, they might have excellent grammar schools brought to their very doors, and thus secure a superior education for their own families, *as well as* adequate instruction for the labouring classes, for a sum far less than what they are now usually paying for the very desultory training which they are obliged to put up with in the boarding-schools of the country. There certainly is no valid reason why a series of higher institutions should not flourish under government patronage and inspection in England, as well as the “gymnasias” do in Germany, the “colleges” in France, and the higher English and classical schools in America.

III. HOW A SYSTEM OF NATIONAL EDUCATION SHOULD BE PRACTICALLY ARRANGED AND CARRIED FORWARD.

Normal
schools.

The first, and perhaps most important point, in a practical system of national education, is to have efficient normal schools for the proper training of teachers. Without these,

National
Education.

no effective instruction is likely to be realized throughout the country at large. It is not enough that a teacher be a man of sufficient learning; his learning must be ready for use. He must understand the character of childhood, and know how to interest it; he must be able to exercise strict discipline without severity; he must comprehend the best methods of school organization, and adapt his plans to the precise wants of his scholars; he must be able to anticipate their difficulties, smooth their path, encourage their efforts, chide their indolence, excite their emulation, and lead them on from one step of mental development to another. All this can only be accomplished by a *special training* for the purpose, and such a training it is the office of the normal school to afford. Study and practice must there go together, so that when the student goes forth to his labour, he may *at once* know what to teach and understand how to teach it. All the countries where education is successfully carried on have laid the foundation for that success in the normal schools; and the best earnest we now have for continued progress in the department of public instruction in our own country lies in those thirty or more normal schools which are forming the minds of more than 2000 pupils for future efficiency as public teachers throughout the country.

The next thing that claims attention is the *organization* of the primary school, and the *method* of instruction. School methods may, by a broad classification, be reduced to three principal types,—these are, *1st*, The monitorial or mutual system; *2d*, The collective or simultaneous system; and *3d*, The sectional system. The monitorial system consists in the employment for a certain period every day of some of the elder boys to assist in the instruction of the younger. The method of Lancaster, who chiefly introduced this system, was to form a monitors' class from the more advanced scholars, to give them special instruction, and then to employ them in giving *back* the lessons they had received to the other children in small groups or drafts. The extravagant expectations which were at first entertained of the efficiency of this method have not been by any means realized. A certain amount of *mechanical* work can be performed by monitors with good effect, and a large amount of drudgery thus taken out of the hands of the teacher; but here their utility ceases. That which the child most needs (and which is the principal educating element in every good school) is, to come into close contact with some superior mind, who knows how to foster and stimulate the germs of thought, to instil sound principles, to correct false or vicious habits, and to insinuate knowledge into the young mind through every avenue by which he can reach it. The idea of committing the education of children, either wholly or principally, to monitors, could only be entertained where the standard aimed at is extremely low and imperfect, neither can the mutual system itself be ever regarded in any other light than a mere substitute for better teaching, where that better teaching cannot be procured.

The collective or simultaneous method errs on the opposite extreme. It collects the whole school together upon a *stage* or *gallery* adapted for the purpose, and attempts to construct a system of lessons such that the whole of the scholars may be taught *at once* by a single master. That this method may serve well for a certain amount of moral training is not to be denied; but as an intellectual instrument it proves extremely defective. Children of different degrees of mental development cannot possibly profit by the same lessons. If those lessons are adapted to the elder scholars, the younger ones are wholly unable to follow them; if they are adapted to the younger scholars, then they are useless to the rest. The simultaneous school is good for making a display, and often surprises those who do not look beneath the surface; but it almost inevitably fosters superficial knowledge, and leaves the child helpless when thrown *alone* upon his own individual resources.

National
Education.

The sectional method is a *via media* between the two extremes I have just described. It goes on the principle that children ought to be classified according to their age and attainments, and a suitable teacher employed for every section. In Prussia the almost universal plan is to make each school-house consist of a number of class-rooms, each class-room being adapted to a single section under one teacher. The same method is followed in the schools of the Christian Brothers in France. When *sufficient*, and at the same time *efficient* teachers can be procured, there can be little doubt that this is the best possible organization for a school, whether primary or secondary. It combines in it every requisite for complete training, whether moral or intellectual. The difficulty of carrying out this system properly, however, becomes great, just in proportion as the number of scholars becomes large. Both in the Prussian schools and those of the Christian Brothers in France, the sections are apt to swell amidst dense populations, to such proportions, that the task becomes too great for a single teacher, and imperfection naturally results.

Various plans have been formed to obviate this difficulty. Amongst others, it was arranged in some of the larger primary schools of Holland that a few of the elder and more advanced scholars should be taken as apprentices in the schools, and employed to teach the lower classes. It was a development of this idea which led to the organization of the pupil-teacher system in England under the Committee of Council on Education.

According to this plan, candidates are examined by the inspectors and reported on to the council-office. If their qualifications are found satisfactory, an indenture is made out, and they are apprenticed to the school for five years; the master being made responsible for their proper training, and their progress being tested by yearly examinations on the ordinary visit of the inspector. The advantages of this plan have proved great. It has enabled every school to adopt a sectional classification; it secures the services continuously, from year to year, of under-teachers, who ordinarily increase every year in intelligence and efficiency; and what is more, it fills the normal schools, not, as was previously the case, with crude, unformed material, but with young men and women who have been well disciplined in the art of teaching, and have had already five years' training in those branches which are most necessary for a teacher thoroughly to understand. Thus, by one and the same arrangement, the schools have been re-organized on sounder principles, and provision has been made for a constant succession of well-trained and well-qualified teachers.

Graduation
of public
schools.

A third important point is the proper *gradation* of public schools. In Prussia there are three principal grades,—viz., 1st, The country school, in which only elementary instruction is given; 2^d, The town school, in which some amount of mathematical and scientific teaching, as well as modern languages, are introduced; and 3^d, The high school or gymnasium, which is throughout constructed on a classical and professional basis.

In Holland there are five grades,—1st, The poor schools, which are wholly gratuitous; 2^d, The intermediate schools, in which a very small fee is paid; 3^d, Town schools, in which there is a higher fee and a higher range of instruction; 4th, The French schools, which prepare for active and commercial life; and 5th, The grammar schools, which prepare for the learned professions antecedently to the universities. The subject of the gradation of schools is now becoming one of the prominent questions in the educational system of America, and will have to become so ere long in our own country.

Schools ne-
cessary in
England.

The simplest classification that can be made for a country like England, where the gradations in society are so marked, will probably be found to be a classification into four distinct grades.—First, we want in all the large towns a series

National
Education.

of *free schools* for the *lowest strata* of society, to occupy thoroughly the whole ground that is now very inadequately taken by the *ragged school*. Next to this come those schools which are at present being so largely established through the country, in which both the nature of the instruction and the entrance-fee are adapted to the wants and resources of the working-classes. Thirdly, we should require a series of town schools, adapted more peculiarly for the mercantile classes, including, in addition to all that is taught in the primary school, the departments of mathematics, science, and modern languages. Fourthly, we should need a proper number of grammar schools, answering to the gymnasia of Germany and the royal or municipal colleges in France, and united to those who intend to embrace a professional life. If such a plan were carried out, every father of a family upon whom a portion of the rates fell would, whatever his sphere in life, get a return far more than equivalent to what he is required to pay. Lastly, with regard to the teachers themselves, if we expect to keep up an efficient staff, two conditions are necessary:—1st, That they be adequately remunerated; and 2^d, That their position be made sufficiently *independent*. The remuneration of teachers must of course depend upon the average rate of payment for men in a similar position of life throughout the country. It must, at any rate, be such that the teacher can live and bring up his family *according to his station*, without seeking extraneous help from other sources. Anything less than this will be sure to deteriorate the profession, by presenting too little inducement for the more energetic minds to continue within its ranks.

The teacher, however, must not only have sufficient remuneration, but his position must be secure and independent so long as he labours with zeal and efficiency. For this purpose, his salary should not depend upon voluntary contributions, which are always fluctuating, and likewise place the teacher too much in the power of the donor; neither should it depend mainly on school-fees, which leads him to pander to the prejudices of parents in order to increase the number of the scholars. The teacher is undoubtedly in the best position when his salary depends on public funds, whether local or governmental, and is responsible, not to any individual, but to a regularly-constituted authority. Where this is the case, he can labour alone for the good of his pupils, and be sure of approbation and support so long as he labours earnestly and intelligently in his sphere.

Conclusion.

In conclusion, let us not forget that the whole subject we have been discussing is one of supreme importance to every country. There is no part of the surface of our globe but bears traces of nations who were once flourishing and progressive, but who have now disappeared, or nearly so, from the rank of civilized communities. The fortunes of every country lie in the spirit of the citizens. Where this is vigorous, enlightened, and moral, the country must *stand*,—nay, must even *advance* on the road towards a still higher and more developed state of society. But where the public mind becomes a prey to ignorance, superstition, and vice, a retrograde movement sets in which leads gradually to disorganization, and finally to absolute dissolution. The history of Germany and of Spain since the time of Charles V. may be taken as an illustration of these two tendencies, presented to us, moreover, in modern times, and in connection with two of the principal nations of Europe. There can be no doubt but that the future of every nation now existing is equally bound up with the cause of popular enlightenment. Whether we regard ourselves, therefore, as philanthropists or as patriots, it is *equally* incumbent upon us to take a *personal* interest in the national education of our country; for it is the sum of *personal interest* which in every free country forms and moulds the character of public opinion; and then it is public opinion which ordains the statutes and shapes the institutions of the realm. (J. D. M.)

Nations,
Law of
||
Nature.

NATIONS, LAW OF. See LAW OF NATIONS.

NATOLIA. See ASIA MINOR.

NATURAL HISTORY. The objects of nature may be considered under two points of view; first, with respect to their form, structure, habits, and individual properties, when viewed in a state of inactivity; and secondly, with respect to the mutual changes which they produce when made to act upon each other. Hence the study of nature may be divided into two parts, namely, Natural History and Natural Science,—the former considering bodies in a comparatively inactive state, and the latter in a state of mutual action. Natural history, then, is that part of natural knowledge which teaches us to distinguish and describe the objects of nature—to examine their appearance, structure, properties, and uses—and to collect, preserve, and arrange them. Some writers divide natural history into *general* and *particular*, which have been accurately defined by Cuvier. *General natural history* considers, under a single point of view, all natural bodies, and the common result of all their actions in the great whole of nature. It determines the laws of the co-existence of their properties; it establishes the degrees of resemblance which exist between different bodies; and it classes them according to these degrees. The *particular natural history* of any body, to be perfect, should comprehend, first, the description of all the sensible properties of that body, and of all its parts; secondly, the mutual relations of these parts, the motions which they produce, and the changes which they undergo whilst they remain united; thirdly, the active and passive relations of this body with every other body in the universe; and fourthly, the explanation of all these phenomena. (See *Tableau Élémentaire d'Histoire Naturelle*.)

(Detailed information respecting the various branches of NATURAL HISTORY will be found under ANIMAL KINGDOM, at the end of which will be found the systematic and alphabetical arrangement of the different sections of the animal kingdom; also under METEOROLOGY, PHYSICAL GEOGRAPHY, MINERALOGICAL SCIENCE, and BOTANY.)

NATURAL PHILOSOPHY is commonly described as that branch of knowledge which treats of the properties of natural bodies, and their actions on one another. This term serves to indicate not one but a cluster of sciences. Those generally comprehended under it are the following, viz.,—Mechanics, theoretical and practical; Hydrostatics and Hydrodynamics; Optics; Astronomy; Magnetism; Electricity. There are, in this work, distinct treatises on all these different branches, introduced in the order of the alphabet; whilst the history of the whole is traced, in a connected method, in the *Fourth, Fifth, and Sixth Preliminary Dissertations*.

NATURALIZATION, the act of naturalizing an alien, or putting him into the condition of a natural-born subject, and entitling him to the rights and privileges of that condition. Previous to the new act (7 and 8 Vict., c. 66) there could be no naturalization except by act of Parliament; but this statute has materially facilitated naturalization, and has made important alterations in the law referring to aliens. (See ALIEN.)

NATURE (*natura*, φύσις) signifies by its etymology the origin and production of existences. But usage has assigned to the term a great number of significations, which are not always clearly distinguished. They are all referable to two classes, however, according as they apply to the nature of some particular thing, or to nature in general. I. When the word is applied to some particular existence, it is used in three distinct senses:—1. As descriptive of the essential qualities of any concrete existence, as distinguished from those qualities which are accidental. 2. As descriptive of the essential qualities of a given genus or species, and by which it is distinguished from every other genus or species. 3. As descriptive of the essence and at-

tributes of the absolute, or of the essence of abstract existences,—as when we speak of the nature of Deity, the nature of the Divine wisdom, the nature of duty, the nature of such and such a law. II. When the word is applied to nature in general, it is employed in four distinct significations:—1. As a collective name for all the forces exerted by man beyond the region of reflective intelligence and will. It is in this sense that *nature* is distinguished from *art* in the development of the human faculties, and in the power put forth by man on the animal, vegetable, and inorganic kingdoms. 2. As a collective term for all corporeal existences as distinguished from incorporeal. It is in this sense that those sciences which deal with material phenomena are termed *natural sciences*. 3. As a term used to designate the permanent but inexplicable fact of the constant production, destruction, and general variability of the phenomena of the universe. Sometimes this fact has been personified and metaphorically endowed with intelligence, volition, desire, and even moral qualities; and philosophers have not unfrequently been the dupes of this figure of speech. Nature, which in this sense was the expression of a fact to be explained, thus became, in the hands of not a few, the general explanation of all the special phenomena connected with this universal fact. 4. As the name given to that productive, destructive, or modifying force, which, whether considered as one or many, created or uncreated, possessing self-intelligence or the blind work of a creating intelligence, is the cause of all the changes which take place in the universe beyond the sphere of the volition of men and animals. The laws of this force are the principal objects of the physical sciences; the objects of natural history are the results of the operations of those laws.

NAUDÉ, GABRIEL, an eminent French bibliographer, was born in Paris in 1600. His love of learning was displayed at an early age, and procured for him the post of librarian to President de Mesmes. But his taste for the science of medicine induced him to remove to Padua in 1626; and there he began that course of medical studies which he afterwards returned to complete in 1633. The death of his father obliged him to repair abruptly to Paris. He lived in the capital till 1631, when he was invited to Rome to become librarian to Cardinal de Baqui. It was while he held this office that the Benedictines and the regular canons of St Geneviève, both zealous for the honour of their respective orders, began their famous controversy concerning the authorship of *De Imitatione Christi*. The former claimed the honour for John Gerson, and the latter for Thomas à Kempis. (See KEMPIS.) Naudé was employed by his master to examine into the dispute, and to give a decision. He decided in favour of à Kempis. This produced a controversy between him and the Benedictines, which passed from a mere literary quarrel into a law-suit, but was ended without a decision in 1652. By this time Cardinal de Baqui had died, and Naudé, after remaining a few months in the service of Cardinal Barberini, had returned to Paris in 1642, and, becoming librarian to Cardinal Mazarin, had enriched with many valuable books and MSS. the library of his master. However, Mazarin was forced to retire from office, and his splendid collection of books was sold by an act of the Parliament of Paris. Naudé accordingly did not hesitate in the same year to accept of the office of librarian to Queen Christina of Sweden; but not long after his arrival at Stockholm his health began rapidly to decline. He set out for his native city, but died by the way, at Abbeville, in July 1653.

The principal of Naudé's numerous works are,—*Apologie pour les Grandes Personnes fausement accusés de Magie*, 8vo, Paris, 1625; *Bibliographia Politica*, Leyden, 1642; *Avis pour Dresser une Bibliothèque*, 8vo, 1644; *Syntagma de Studio Liberali*, 4to, 1632; *Considérations Politiques sur les Coups d'Etat*, 1639; *Instruction à la*

Naudé.

Nauen
||
Naunton.

France sur la Vérité de l'Histoire des Frères de la Rose-Croix, 8vo, Paris, 1623; and *Jugement de tout ce qui a été imprimé contre le Cardinal Mazarin*, 4to, 1650. A book entitled *Naudéana* was published at Paris in 1701.

NAUEN, a town of Prussia, province of Brandenburg, and government of Potsdam, on the Havelbach, 23 miles W.N.W. of Berlin. It contains a church, town-house, and hospital; and has manufactures of linen, beer, and brandy. The greater part of the town was burnt down in 1830. Pop. 4220.

NAUMACHIA, an ancient Roman spectacle representing a sea-fight. It was sometimes exhibited in a circus or amphitheatre filled with water for the occasion; but more generally naval theatres, surrounded with seats and porticoes, and named after the spectacle itself *naumachie*, were constructed. The most celebrated of these were that of Julius Cæsar in the Campus Martius, that of Augustus near the Tiber, and that of Domitian surrounded with an erection of stone. Claudius preferred to exhibit his naval shows on the Lake Fucinus. The *naumachiarii*, as the combatants were called, were usually captives or condemned malefactors. They were drawn up in two great opposing squadrons, distinguished by the names of any two maritime nations, and were doomed to fight until the one party had exterminated the other, unless the emperor, or the private person who had given the entertainment, put a stop to the engagement. The *naumachie*, like other Roman games, were often celebrated with the most extravagant pomp and magnificence. Artificial nereids and sea-monsters were sometimes seen swimming among the ships; and the sight of two large fleets grappling with each other in deadly combat, to amuse a crowd of idle spectators, was no uncommon occurrence.

NAUMBURG, a town of Prussia, province of Saxony, pleasantly situated in the midst of vine-covered hills in the valley of the Saale, 18 miles S.S.W. of Merseburg. The town consists of a walled portion and three suburbs. It is well built, and contains some fine streets and public buildings. The cathedral, which is partly in the Gothic and partly in the Romanesque style, was completed in 1249; but several additions have since been made. It has a choir at each end, and of these the western is the more ancient. The interior contains many curious monuments, sculptures, and specimens of painted glass. There are several other churches in the town, one of which, that of St Wenzel, contains a fine painting by L. Cranach. Naumburg has also a citadel, town-hall, arsenal, a high school, an industrial school, and several hospitals. Manufactures of carriages, woollen cloth, hosiery, shoes, chemicals, &c., are carried on. This is one of the most northerly places in Europe where the vine is cultivated, but the wine produced is little better than vinegar. Some trade is carried on in the articles of manufacture, as well as in oil, wine, wool, &c.; and two fairs are annually held. Naumburg was besieged in 1482 by the Hussites under Procopius; but they were induced to raise the siege by the entreaties of the children of the town. This event has been dramatized by Kotzebue, and is still celebrated by an annual children's festival on the 28th of July. Naumburg was a place of importance in the Thirty Years' War, as well as in the campaigns of 1806 and 1813. Pop. 13,802.

NAUNTON, SIR ROBERT, secretary of state to James I., was born in 1563 in Suffolk, and was educated at Trinity College, Cambridge. His public life was begun by an embassy to Scotland in 1589. The Earl of Essex afterwards employed him to reside in France under the guise of tutor to a young gentleman named Vernon, but in reality as a spy on the French government. On the fall of his patron, he seems to have returned home; and in 1601 was elected public orator in the university of Cam-

bridge. It was there that his learning introduced him to the notice and patronage of James I. After passing through several political offices, he was appointed secretary of state in 1618. Sir Robert Naunton died in 1635. His chief work, *Fragmenta Regalia, or Observations on the late Queen Elizabeth, her Times and Favourites*, was published in 4to, 1641. He is also the author of *Arcana Aulica*, 8vo, 1694; and *Memoirs of Robert Cary, Earl of Monmouth*.

NAUPACTUS. See LEPANTO.

NAUPLIA, or NAPOLI-DI-ROMANIA, a town of Greece, in the Morea, at the head of the gulf formerly called the Argolic, but which now bears the name of the town; in N. Lat. 37. 34., E. Long. 22. 48. It stands on the N.E. side of a flat-topped hill, on the summit of which is a castle called Palamidhi, one of the strongest places in Europe. This hill stands on a peninsula, to the N. of which is the harbour of the town, large and well sheltered, but not deep enough to admit large vessels. The most of the streets of Nauplia are narrow, though straight; but several wide and handsome streets have been recently built; while the whole town, instead of the wretched and dirty appearance which it formerly presented, has now a neat and clean appearance, like that of a second-rate Italian seaport. There are two squares, which are connected by the main street running through the middle of the town; and the principal public buildings, besides the churches, are the royal palace, the court-house, and the barracks. Nauplia has a military academy, a school for the middle classes, a circulating library, and other literary establishments. The town is surrounded by Venetian fortifications, and is defended by a battery and by another fortress besides the one which stands on the top of the hill. A considerable trade was formerly carried on here by Greek vessels in corn, wine, oil, silk, fruits, &c.; but this has considerably declined, and the only articles in which there is now any commerce are the necessaries of life. The climate is unhealthy, and the town has been frequently exposed to the ravages of pestilence. In ancient times the site was occupied by a town of the same name. It was of great antiquity, and is said by Pausanias to have been founded by the colony of Egyptians whom Danaus brought with him. That it was a town of foreign origin may be inferred with probability from the contrast between its situation, on a promontory of the coast, and those of the other ancient Greek towns among the mountains and glens of the interior. It was at first an independent town, but in the seventh century B.C. was conquered by the Argives, and Nauplia then became merely the seaport of Argos. In the second century it is described by Pausanias as deserted, and as having some remains of a temple of Neptune. About the time of the Crusades, it rose to be a town of some importance, under the name of *Anaplion* or *Anaplia*, which has since been changed by the restoration of the ancient appellation. It was occupied in the thirteenth century by the Venetians, and made by them the chief of their settlements in the Morea. Taken by the Sultan Solymán in 1537, but soon afterwards retaken, it was not finally added to the dominions of the Porte till 1718. The Turks again lost it on the outbreak of the Greek insurrection, and it was the seat of the new government from 1829 till 1834, when that honour was transferred to Athens. It is peopled to a large extent by foreigners from France, Germany, and Italy. Pop. estimated at 15,000.

NAUVOO, a town of the United States, North America, state of Illinois, on the left bank of the Mississippi, 52 miles above Quincy, and 220 above St Louis. It was founded by the Mormons in 1840, and laid out with great regularity on a tract of ground gradually sloping upwards from the river's edge. The principal building was the Mormon temple, a large limestone edifice, containing a stone baptistry

Naupactus
||
Nauvoo.

Navan
||
Navarra.

supported by twelve large oxen. This building was burned down in 1848; when the Mormons were forcibly expelled from the state and obliged to emigrate to Utah. A company of French socialists have recently established themselves here. The population while the Mormons occupied the town was from 15,000 to 18,000, but in 1850 it was only 1130.

NAVAN, a market-town of Ireland, county of Meath, pleasantly situated on a hill at the confluence of the rivers Boyne and Blackwater, 28 miles N.W. of Dublin. The town is not well built; and the principal streets, of which there are four, though straight, are not clean. A bridge over the Boyne connects it with the suburb of Athlumney, and another over the Blackwater with that of Donaghmore. The parish church is a neat building, erected in 1818; and there is also a fine Roman Catholic chapel. There are also a court-house and market-house, bridewell, cavalry barracks, infirmary, dispensary, fever hospital, union workhouse, Roman Catholic convent and diocesan seminary, and national and other schools. It is connected with Drogheda by a railway and canal, by means of which it carries on some trade, chiefly in corn and other agricultural produce. There are in the town several flour, flax, and paper mills, a tannery, brewery, and two distilleries. Previous to the union, Navan returned two members to the Irish Parliament. Pop. 3626.

NAVARINO, a town of Greece in the Morea, stands at the south end of a bay of the same name, 136 miles S.W. of Athens, and 92. S. by W. of Patras; N. Lat. 36. 54., E. Long. 21. 41. It consists of a citadel, situated on a high rock, and a lower town; the whole being surrounded by walls, but having no ditch. The streets are narrow, steep, and dirty, and the houses meanly and irregularly built, many of them being also in a ruinous condition. Those near the sea, however, are of a somewhat better sort. The town contains the remains of an old aqueduct and some ancient marble pillars, which now adorn the front of the principal mosque. The Bay of Navarino forms one of the best harbours in Greece. It is about 4 miles in length by 2 in breadth, and the depth varies from 12 to 26 fathoms. It is protected towards the W. by the long and narrow island of Sphagia (anciently *Sphacteria*), to the S.E. of which lies the entrance, which is nearly a mile wide. The ancient town of Pylos stood at the northern end of the bay; and there was formerly a navigable channel to the north of the island, though narrower than that to the south; but it is now so shallow as not to admit of the passage of ships. In the sixth century a colony of the Avars settled here, from whom probably the place got the name of *Avarino*, which has been changed, like many other modern names in Greece, by prefixing the terminal letter of the accusative of the article. Navarino is famous in modern history for the victory gained here over the Turkish and Egyptian fleets by those of Great Britain, France, and Russia, October 20, 1827. This engagement was occasioned by the breach of an armistice on the part of the Turks, and the result was the destruction of nearly the whole Ottoman fleet, and the establishment of the independence of the Greeks. The population of the town at present does not exceed 2000.

NAVARRA, a province of Spain, in the N.E., between 41. 55. 34. and 43. 18. 36. N. Lat., with the following boundaries:—N., France and the province of Guipuzcoa; E., Zaragoza; S., Zaragoza and Logroño; W., Alava. In shape it is an irregular square, 80 miles long and about 70 broad, and has an area of about 2450 square miles. Three-fourths of the surface (its northern and eastern districts) are mountainous and rugged, broken by ramifications of the Pyrenees, which present on the N.E. an almost impassable barrier, and inclose numberless secluded pastoral valleys. The northern frontier is pierced by several defiles, well-known passes,—as Roncesvallés, Bastan, and Roncal,—

Navarra.

thoroughfares of war and commerce between France and the Peninsula. The highest summits in Navarra are those of Altoviscar and Adi,—the former 5380, the latter 5220 feet above the sea. South of a line from Sanguesa by Tafalla to Estella, the country presents a series of descending terraces, extending towards Zaragoza, Soria, and Logroño. The principal rivers of the province are the Bidasoa and the Ebro; the former in the N.W., formed by the confluence of the Baztan and the Ezcurra; the latter in the S. The rivers, which, according to the proverb, "make a man of the Ebro," are the Aragon, which enters Navarra on the E. from Aragon, and has a course in the province of about 80 miles; the Ega, which enters from Guipuzcoa, and falls into the Ebro near Uzaire, after a course of about 100 miles; and the Arga, which descends from the Pyrenees, and has a course of 120 miles before its confluence with the Aragon. The mountainous region contains numerous quarries of gypsum, limestone of various kinds, and free-stone. Granite, slate, jasper, black and other marbles, frequently occur. There are also numerous mines of iron, lead, and copper, the most important of which have been found in the argillaceous slate; as of copper in the neighbourhood of Leiza, of lead near Vera and Leiza, of iron in many places, as near Goizueta, Vera, and in the valley of Aezcoa. These mines employ a considerable population; but for want of capital and enterprise, and good communication, have never been very flourishing, and mining industry has now much decayed. There are two large mines of rock-salt at Funes and Valtierra; and salt is also obtained in various places by atmospheric and artificial evaporation. Agriculture, properly speaking, is confined to the plain, much of which is rich, well cultivated, and fertile, producing wheat, maize, hemp, flax, oil, and wine. The wines of Tudela and Peralta are celebrated. Were full advantage taken of the numerous streams for irrigation, the hilly district might be extensively cultivated; as it is, it is almost exclusively appropriated to forests and pasture. The oak, beech, and pine are grown for wood; and the chestnut affords an article of home consumption. The cultivation of the mulberry for the silk-worm is not unknown. Great quantities of horned cattle, sheep, goats, pigs, and mules are reared. Game of all kinds is abundant in the mountains; and the streams abound with trout and other fish.

The manufactures of Navarra are insignificant. Linen cloth is made in Pamplona; paper in Villaba; in various places, silk, woollens, pottery, soap, chocolate, liquorice, and some other articles. Iron is exported to America by San Sebastian and Bilbao; the exports to France are wool, iron, salt, hides, and liquorice, in exchange for silks, linens, woollens, and hardware. To Aragon and Castile are exported wheat, beans, iron, articles in boxwood, brandy, fruit, and vegetables; and to the Basque provinces, wheat, oil, brandy, cattle, salt, and wine. For the internal trade, there are the fairs of Tafalla, Tudela, Sanguesa, and Pamplona, in February, March, and June, respectively. There are two institutions of secondary instruction in Pamplona and Tudela, and 508 schools of different kinds in the province, mostly elementary, and ill supported. Education is in a very backward state. The two great districts of the province, hill and plain, are inhabited by distinct races, of different language, dress, and customs; the prevailing language in the north being Basque, in the south Castilian. The population of the plain are rude, addicted to drunkenness and crime; those of the mountains are hospitable, polite, and honest. The Navarrese are noted in the Peninsula for integrity, sagacity, and enterprise. During the war of independence and the civil war, the province produced bands of formidable guerilleros; and it still produces, owing to the position and nature of the frontier, daring and formidable contrabandistas. Large numbers emigrate to other parts of the Peninsula, and recently to America. The ancient

Navarrete. kingdom of Navarra included the French or Lower Navarre, and was a separate Spanish monarchy from A.D. 1114. Jean d'Albert, to whom it came by marriage, was despoiled by Ferdinand the Catholic of the Spanish portion in 1512. Till lately that portion had a much wider boundary, and was governed by its own laws as a vice-royalty. Navarra suffered severely in the French and civil wars. The united population of the five partidos, Aviz, Estella, Pamplona, Tafalla, and Tudela, amounted in 1849 to 235,874.

NAVARRETE, DOMINGO FERNANDEZ, a Spanish missionary, was born at Peñafiel in the first half of the seventeenth century, and was educated at Valladolid as a Dominican. In 1647 he set sail on a mission to the Philippine Islands. There his learning soon recommended him to the post of first professor of theology in the college of Manila. He repaired, however, in 1659 to China, and was busily engaged in the interior of the country studying the Chinese language, manners, and customs, when the jealous natives raised a persecution against the Christian missionaries. Navarrete, along with some of his brethren, was sent a prisoner to Canton; but contriving to escape to Macao, he set sail homewards, and arrived in Europe in 1673. In the same year he paid a visit to Rome, and had an interview with the Pope. His account before the Supreme Pontiff of the state of the Chinese mission was accompanied with a strong protest against the temporizing policy which the Jesuit missionaries used in dealing with the superstitions of the natives. After his return to Spain, Navarrete published his principal work, entitled *Tratados, historicos, politicos, ethicos, y religiosos de la Monarchia de China*, fol., Madrid, 1676. At length, in 1678, he was rewarded for his eminent services by being appointed archbishop of San Domingo in the West Indies. His death happened there in 1689. The sixth book of the above-mentioned work of Navarrete was translated into English under the title of *A Collection of Voyages and Travels*, fol., Lond. 1704.

NAVARRETE, Juan Fernandez, surnamed *El Mudo* ("the Mute"), an eminent Spanish painter, was born at Logroño in Castile in 1526. In early infancy an attack of disease quenched entirely his sense of hearing, and consequently left him without the faculty of acquiring speech. But the quick and intelligent boy soon contrived to express his wants by sketching objects with a piece of charcoal. The practice thus begun as, a necessity was soon prosecuted as an art. He was placed under the tuition of Fray Vicente de Santo Domingo, a monkish painter, at Estrella. Meanwhile the rest of his training was not neglected. He learned to read and write, became well versed in history, both sacred and profane, and acquired a remarkable skill in expressing his ideas by signs. His ready talents also soon exhausted all the lessons in art that his master could give him, and he repaired to Italy to finish his studies there. He visited Florence, Rome, Naples, and Milan; and, according to the ordinary account, sat for a considerable time in the school of Titian at Venice. But it was long before the labours of the poor dumb artist attracted much notice. At length, in 1568, the Spanish king, Philip II., summoned him to Madrid, conferred upon him the title of royal painter and a salary of 200 ducats a year, and employed him to execute

pictures for the Escorial. The peculiar style of *El Mudo* now developed itself. His pencil exhibited a striking boldness and freedom in design, and his rich, warm colouring acquired for him the surname of "the Spanish Titian." These qualities were well exemplified in "The Assumption," "The Martyrdom of St James the Great," "St Philip," and a "Repenting St Jerome," all of which he had executed by 1571. During the next four years he was engaged in painting "The Nativity," "The Scourging of Christ," and "The Holy Family." A life-like yet somewhat incongruous feature in the last of these was the representation of a cat and a dog in the foreground showing fight over a bone. His great work, "Abraham receiving the Three Angels," followed in 1576. The two remaining years of his life were spent in painting for the chapel of the Escorial eight altar-pieces, which still excite the admiration of visitors by their noble figures and their full and warmly-coloured draperies. *El Mudo* died at Toledo in February 1579. (See Stirling's *Annals of the Artists of Spain*, in 3 vols., London, 1848.)

NAVARRETE, Martin Fernandez de, a Spanish historian, was born at Abalos in Old Castile in 1765. After receiving his education at Vergara, he entered the navy as a midshipman in 1780. His ship was engaged in the unsuccessful siege of Gibraltar in 1782, and afterwards in the cruises against the Algerines and other pirates that infested the Mediterranean. Declining health, however, forced him to retire from active service in 1789. Meanwhile, in addition to his professional knowledge, he had been steadily acquiring an accurate acquaintance with history. The Spanish king, Charles IV., therefore fixed upon him as the proper person for compiling a collection of documents touching the maritime history of the country; and Navarrete set himself perseveringly to search the national archives. But new duties and other causes of interruption repeatedly retarded his great undertaking. The war, first against the French and subsequently against the British, kept him at his post on board the fleet from 1793 to 1797. Then he received an appointment in the office of the minister of marine. The invasion of the French happened in 1808, and forced him to remove to Seville. Other tasks occupied his attention after the restoration of Ferdinand VII. At length, in 1825, the first and second volumes of his gigantic work appeared under the title of *Coleccion de los Viajes y Descubrimientos que hicieron por mar los Españoles desde fines del siglo XV*. The third followed in 1829, and the fourth and fifth in 1837. Before the sixth and seventh could be published the author died in 1844.

The work of Navarrete, already mentioned, has been described by Humboldt as "one of the most important historical monuments of modern times." The industrious compiler was also assisting at the time of his death in the publishing of the *Coleccion de Documentos Ineditos para la Historia de España*. A Life of Cervantes by Navarrete, printed in 8vo, Madrid, 1819, is said by Ticknor to be "one of the most judicious and best-arranged biographical works that have been published in any country." It furnished the materials for Thomas Roscoe's Life of the same author, published in 18mo, London, 1839. Navarrete was also the author of several lesser historical and biographical works.
